
**import\_proj** (*proj*)

Import spatial reference from PROJ.4 string.

**import\_user\_input** (*user\_input*)

**import\_wkt** (*wkt*)

Import spatial reference from WKT.

**import\_xml** (*xml*)

Import spatial reference from XML.

**name**

Returns the name of this Spatial Reference.

**srid**

Returns the SRID of top-level authority, or `None` if undefined.

**linear\_name**

Returns the name of the linear units.

**linear\_units**

Returns the value of the linear units.

**angular\_name**

Returns the name of the angular units.”

**angular\_units**

Returns the value of the angular units.

**units**

Returns a 2-tuple of the units value and the units name and will automatically determines whether to return the linear or angular units.

**ellipsoid**

Returns a tuple of the ellipsoid parameters for this spatial reference: (semimajor axis, semiminor axis, and inverse flattening).

**semi\_major**

Returns the semi major axis of the ellipsoid for this spatial reference.

**semi\_minor**

Returns the semi minor axis of the ellipsoid for this spatial reference.

**inverse\_flattening**

Returns the inverse flattening of the ellipsoid for this spatial reference.

**geographic**

Returns `True` if this spatial reference is geographic (root node is GEOGCS).

**local**

Returns `True` if this spatial reference is local (root node is LOCAL\_CS).

**projected**

Returns `True` if this spatial reference is a projected coordinate system (root node is PROJCS).

**wkt**

Returns the WKT representation of this spatial reference.

**pretty\_wkt**

Returns the 'pretty' representation of the WKT.

**proj**

Returns the PROJ.4 representation for this spatial reference.

**proj4**

Alias for `SpatialReference.proj`.

**xml**

Returns the XML representation of this spatial reference.

**CoordTransform**

**class** `CoordTransform` (*source*, *target*)

Represents a coordinate system transform. It is initialized with two `SpatialReference`, representing the source and target coordinate systems, respectively. These objects should be used when performing the same coordinate transformation repeatedly on different geometries:

```
>>> ct = CoordTransform(SpatialReference('WGS84'), SpatialReference('NAD83'))
>>> for feat in layer:
...     geom = feat.geom # getting clone of feature geometry
...     geom.transform(ct) # transforming
```

## Raster Data Objects

### GDALRaster

*GDALRaster* is a wrapper for the GDAL raster source object that supports reading data from a variety of GDAL-supported geospatial file formats and data sources using a simple, consistent interface. Each data source is represented by a *GDALRaster* object which contains one or more layers of data named bands. Each band, represented by a *GDALBand* object, contains georeferenced image data. For example, an RGB image is represented as three bands: one for red, one for green, and one for blue.

**Note:** For raster data there is no difference between a raster instance and its data source. Unlike for the Geometry objects, *GDALRaster* objects are always a data source. Temporary rasters can be instantiated in memory using the corresponding driver, but they will be of the same class as file-based raster sources.

**class** *GDALRaster* (*ds\_input*, *write=False*)

The constructor for *GDALRaster* accepts two parameters. The first parameter defines the raster source, it is either a path to a file or spatial data with values defining the properties of a new raster (such as size and name). If the input is a file path, the second parameter specifies if the raster should be opened with write access. If the input is raw data, the parameters *width*, *height*, and *srid* are required. The following example shows how rasters can be created from different input sources (using the sample data from the GeoDjango tests, see also the *Sample Data* section):

```
>>> from django.contrib.gis.gdal import GDALRaster
>>> rst = GDALRaster('/path/to/your/raster.tif', write=False)
>>> rst.name
'/path/to/your/raster.tif'
>>> rst.width, rst.height           # This file has 163 x 174 pixels
(163, 174)
>>> rst = GDALRaster({'srid': 4326, 'width': 1, 'height': 2, 'datatype': 1
...                  'bands': [{'data': [0, 1]}]}) # Creates in-memory raster
>>> rst.srs.srid
4326
>>> rst.width, rst.height
(1, 2)
>>> rst.bands[0].data()
array([[0, 1]], dtype=int8)
```

*GDALRaster* objects can now be instantiated directly from raw data. Setters have been added for the following properties: *srs*, *geotransform*, *origin*, *scale*, and *skew*.

#### name

The name of the source which is equivalent to the input file path or the name provided upon instantiation.

```
>>> GDALRaster({'width': 10, 'height': 10, 'name': 'myraster', 'srid': 4326}).
↪name
'myraster'
```

#### driver

The name of the GDAL driver used to handle the input file. For *GDALRasters* created from a file, the driver type is detected automatically. The creation of rasters from scratch is an in-memory raster by default ('MEM'), but can be altered as needed. For instance, use *GTiff* for a *GeoTiff* file. For a list of file types, see also the [GDAL Raster Formats](#) list.

An in-memory raster is created through the following example:

```
>>> GDALRaster({'width': 10, 'height': 10, 'srid': 4326}).driver.name
'MEM'
```

A file based GeoTiff raster is created through the following example:

```
>>> import tempfile
>>> rstfile = tempfile.NamedTemporaryFile(suffix='.tif')
>>> rst = GDALRaster({'driver': 'GTiff', 'name': rstfile.name, 'srid': 4326,
...                  'width': 255, 'height': 255, 'nr_of_bands': 1})
>>> rst.name
'/tmp/tmp7x9H4J.tif'          # The exact filename will be different on your_
↪computer
>>> rst.driver.name
'GTiff'
```

### width

The width of the source in pixels (X-axis).

```
>>> GDALRaster({'width': 10, 'height': 20, 'srid': 4326}).width
10
```

### height

The height of the source in pixels (Y-axis).

```
>>> GDALRaster({'width': 10, 'height': 20, 'srid': 4326}).height
20
```

### srs

The spatial reference system of the raster, as a *SpatialReference* instance. The SRS can be changed by setting it to an other *SpatialReference* or providing any input that is accepted by the *SpatialReference* constructor.

```
>>> rst = GDALRaster({'width': 10, 'height': 20, 'srid': 4326})
>>> rst.srs.srid
4326
>>> rst.srs = 3086
>>> rst.srs.srid
3086
```

### srid

The Spatial Reference System Identifier (SRID) of the raster. This property is a shortcut to getting or setting the SRID through the *srs* attribute.

```
>>> rst = GDALRaster({'width': 10, 'height': 20, 'srid': 4326})
>>> rst.srid
4326
>>> rst.srid = 3086
>>> rst.srid
3086
>>> rst.srs.srid # This is equivalent
3086
```

### geotransform

The affine transformation matrix used to georeference the source, as a tuple of six coefficients which map pixel/line coordinates into georeferenced space using the following relationship:

```
Xgeo = GT(0) + Xpixel*GT(1) + Yline*GT(2)
Ygeo = GT(3) + Xpixel*GT(4) + Yline*GT(5)
```

The same values can be retrieved by accessing the *origin* (indices 0 and 3), *scale* (indices 1 and 5) and *skew* (indices 2 and 4) properties.

The default is `[0.0, 1.0, 0.0, 0.0, 0.0, -1.0]`.

```
>>> rst = GDALRaster({'width': 10, 'height': 20, 'srid': 4326})
>>> rst.geotransform
[0.0, 1.0, 0.0, 0.0, 0.0, -1.0]
```

### origin

Coordinates of the top left origin of the raster in the spatial reference system of the source, as a point object with *x* and *y* members.

```
>>> rst = GDALRaster({'width': 10, 'height': 20, 'srid': 4326})
>>> rst.origin
[0.0, 0.0]
>>> rst.origin.x = 1
>>> rst.origin
[1.0, 0.0]
```

### scale

Pixel width and height used for georeferencing the raster, as a as a point object with *x* and *y* members. See *geotransform* for more information.

```
>>> rst = GDALRaster({'width': 10, 'height': 20, 'srid': 4326})
>>> rst.scale
[1.0, -1.0]
>>> rst.scale.x = 2
>>> rst.scale
[2.0, -1.0]
```

### skew

Skew coefficients used to georeference the raster, as a point object with *x* and *y* members. In case of north up images, these coefficients are both 0.

```
>>> rst = GDALRaster({'width': 10, 'height': 20, 'srid': 4326})
>>> rst.skew
[0.0, 0.0]
>>> rst.skew.x = 3
>>> rst.skew
[3.0, 0.0]
```

### extent

Extent (boundary values) of the raster source, as a 4-tuple (*xmin*, *ymin*, *xmax*, *ymax*) in the spatial reference system of the source.

```
>>> rst = GDALRaster({'width': 10, 'height': 20, 'srid': 4326})
>>> rst.extent
(0.0, -20.0, 10.0, 0.0)
>>> rst.origin.x = 100
>>> rst.extent
(100.0, -20.0, 110.0, 0.0)
```

### bands

List of all bands of the source, as *GDALBand* instances.

```
>>> rst = GDALRaster({"width": 1, "height": 2, 'srid': 4326,
...                  "bands": [{"data": [0, 1]}, {"data": [2, 3]}]})
>>> len(rst.bands)
2
>>> rst.bands[1].data()
array([[ 2.,  3.]], dtype=float32)
```

**warp** (*ds\_input*, *resampling='NearestNeighbour'*, *max\_error=0.0*)

Returns a warped version of this raster.

The warping parameters can be specified through the *ds\_input* argument. The use of *ds\_input* is analogous to the corresponding argument of the class constructor. It is a dictionary with the characteristics of the target raster. Allowed dictionary key values are width, height, SRID, origin, scale, skew, datatype, driver, and name (filename).

By default, the warp functions keeps most parameters equal to the values of the original source raster, so only parameters that should be changed need to be specified. Note that this includes the driver, so for file-based rasters the warp function will create a new raster on disk.

The only parameter that is set differently from the source raster is the name. The default value of the the raster name is the name of the source raster appended with `'_copy' + source_driver_name`. For file-based rasters it is recommended to provide the file path of the target raster.

The resampling algorithm used for warping can be specified with the *resampling* argument. The default is `NearestNeighbor`, and the other allowed values are `Bilinear`, `Cubic`, `CubicSpline`, `Lanczos`, `Average`, and `Mode`.

The *max\_error* argument can be used to specify the maximum error measured in input pixels that is allowed in approximating the transformation. The default is 0.0 for exact calculations.

For users familiar with GDAL, this function has a similar functionality to the `gdalwarp` command-line utility.

For example, the warp function can be used for aggregating a raster to the double of its original pixel scale:

```
>>> rst = GDALRaster({
...     "width": 6, "height": 6, "srid": 3086,
...     "origin": [500000, 400000],
...     "scale": [100, -100],
...     "bands": [{"data": range(36), "nodata_value": 99}]
... })
>>> target = rst.warp({"scale": [200, -200], "width": 3, "height": 3})
>>> target.bands[0].data()
array([[ 7.,  9., 11.],
       [19., 21., 23.],
       [31., 33., 35.]], dtype=float32)
```

**transform** (*srid*, *driver=None*, *name=None*, *resampling='NearestNeighbour'*, *max\_error=0.0*)

Returns a transformed version of this raster with the specified SRID.

This function transforms the current raster into a new spatial reference system that can be specified with an *srid*. It calculates the bounds and scale of the current raster in the new spatial reference system and warps the raster using the *warp* function.

By default, the driver of the source raster is used and the name of the raster is the original name appended with `'_copy' + source_driver_name`. A different driver or name can be specified with the *driver* and *name* arguments.

The default resampling algorithm is `NearestNeighbour` but can be changed using the *resampling* argument. The default maximum allowed error for resampling is 0.0 and can be changed using the

`max_error` argument. Consult the *warp* documentation for detail on those arguments.

```
>>> rst = GDALRaster({
...     "width": 6, "height": 6, "srid": 3086,
...     "origin": [500000, 400000],
...     "scale": [100, -100],
...     "bands": [{"data": range(36), "nodata_value": 99}]
... })
>>> target = rst.transform(4326)
>>> target.origin
[-82.98492744885776, 27.601924753080144]
```

## GDALBand

### class GDALBand

GDALBand instances are not created explicitly, but rather obtained from a *GDALRaster* object, through its *bands* attribute. The GDALBands contain the actual pixel values of the raster.

#### description

The name or description of the band, if any.

#### width

The width of the band in pixels (X-axis).

#### height

The height of the band in pixels (Y-axis).

#### pixel\_count

The total number of pixels in this band. Is equal to `width * height`.

#### statistics (*refresh=False, approximate=False*)

Compute statistics on the pixel values of this band. The return value is a tuple with the following structure: (minimum, maximum, mean, standard deviation).

If the `approximate` argument is set to `True`, the statistics may be computed based on overviews or a subset of image tiles.

If the `refresh` argument is set to `True`, the statistics will be computed from the data directly, and the cache will be updated with the result.

If a persistent cache value is found, that value is returned. For raster formats using Persistent Auxiliary Metadata (PAM) services, the statistics might be cached in an auxiliary file. In some cases this metadata might be out of sync with the pixel values or cause values from a previous call to be returned which don't reflect the value of the `approximate` argument. In such cases, use the `refresh` argument to get updated values and store them in the cache.

For empty bands (where all pixel values are “no data”), all statistics are returned as `None`.

The statistics can also be retrieved directly by accessing the *min*, *max*, *mean*, and *std* properties.

#### min

The minimum pixel value of the band (excluding the “no data” value).

#### max

The maximum pixel value of the band (excluding the “no data” value).

#### mean

The mean of all pixel values of the band (excluding the “no data” value).

**std**

The standard deviation of all pixel values of the band (excluding the “no data” value).

**nodata\_value**

The “no data” value for a band is generally a special marker value used to mark pixels that are not valid data. Such pixels should generally not be displayed, nor contribute to analysis operations.

To delete an existing “no data” value, set this property to `None` (requires GDAL  $\geq$  2.1).

This property can now be set as well.

The “no data” value can now be deleted by setting the `nodata_value` attribute to `None`.

**datatype** (*as\_string=False*)

The data type contained in the band, as an integer constant between 0 (Unknown) and 11. If `as_string` is `True`, the data type is returned as a string with the following possible values: `GDT_Unknown`, `GDT_Byte`, `GDT_UInt16`, `GDT_Int16`, `GDT_UInt32`, `GDT_Int32`, `GDT_Float32`, `GDT_Float64`, `GDT_CInt16`, `GDT_CInt32`, `GDT_CFloat32`, and `GDT_CFloat64`.

**data** (*data=None, offset=None, size=None, shape=None*)

The accessor to the pixel values of the `GDALBand`. Returns the complete data array if no parameters are provided. A subset of the pixel array can be requested by specifying an offset and block size as tuples.

If NumPy is available, the data is returned as NumPy array. For performance reasons, it is highly recommended to use NumPy.

Data is written to the `GDALBand` if the `data` parameter is provided. The input can be of one of the following types - packed string, buffer, list, array, and NumPy array. The number of items in the input should normally correspond to the total number of pixels in the band, or to the number of pixels for a specific block of pixel values if the `offset` and `size` parameters are provided.

If the number of items in the input is different from the target pixel block, the `shape` parameter must be specified. The shape is a tuple that specifies the width and height of the input data in pixels. The data is then replicated to update the pixel values of the selected block. This is useful to fill an entire band with a single value, for instance.

For example:

```
>>> rst = GDALRaster({'width': 4, 'height': 4, 'srid': 4326, 'datatype': 1,
↳ 'nr_of_bands': 1})
>>> bnd = rst.bands[0]
>>> bnd.data(range(16))
>>> bnd.data()
array([[ 0,  1,  2,  3],
       [ 4,  5,  6,  7],
       [ 8,  9, 10, 11],
       [12, 13, 14, 15]], dtype=int8)
>>> bnd.data(offset=(1, 1), size=(2, 2))
array([[ 5,  6],
       [ 9, 10]], dtype=int8)
>>> bnd.data(data=[-1, -2, -3, -4], offset=(1, 1), size=(2, 2))
>>> bnd.data()
array([[ 0,  1,  2,  3],
       [ 4, -1, -2,  7],
       [ 8, -3, -4, 11],
       [12, 13, 14, 15]], dtype=int8)
>>> bnd.data(data='\x9d\xa8\xb3\xbe', offset=(1, 1), size=(2, 2))
>>> bnd.data()
array([[ 0,  1,  2,  3],
       [ 4, -99, -88,  7],
```

```

    [ 8, -77, -66, 11],
    [12, 13, 14, 15]], dtype=int8)
>>> bnd.data([1], shape=(1, 1))
>>> bnd.data()
array([[1, 1, 1, 1],
       [1, 1, 1, 1],
       [1, 1, 1, 1],
       [1, 1, 1, 1]], dtype=uint8)
>>> bnd.data(range(4), shape=(1, 4))
array([[0, 0, 0, 0],
       [1, 1, 1, 1],
       [2, 2, 2, 2],
       [3, 3, 3, 3]], dtype=uint8)

```

The shape parameter and the ability to replicate data input when setting GDALBand data was added.

## Settings

### GDAL\_LIBRARY\_PATH

A string specifying the location of the GDAL library. Typically, this setting is only used if the GDAL library is in a non-standard location (e.g., /home/john/lib/libgdal.so).

## Geolocation with GeoIP

Deprecated since version 1.9: This module is deprecated in favor of [django.contrib.gis.geopip2](#), which supports IPv6 and the GeoLite2 database format.

The *GeoIP* object is a ctypes wrapper for the [MaxMind GeoIP C API](#).<sup>1</sup>

In order to perform IP-based geolocation, the *GeoIP* object requires the GeoIP C library and either the GeoIP Country or City datasets in binary format (the CSV files will not work!). These datasets may be [downloaded from MaxMind](#). Grab the GeoLiteCountry/GeoIP.dat.gz and GeoLiteCity.dat.gz files and unzip them in a directory corresponding to what you set *GEOIP\_PATH* with in your settings. See the example and reference below for more details.

## Example

Assuming you have the GeoIP C library installed, here is an example of its usage:

```

>>> from django.contrib.gis.geopip import GeoIP
>>> g = GeoIP()
>>> g.country('google.com')
{'country_code': 'US', 'country_name': 'United States'}
>>> g.city('72.14.207.99')
{'area_code': 650,
 'city': 'Mountain View',
 'country_code': 'US',
 'country_code3': 'USA',
 'country_name': 'United States',
 'dma_code': 807,
 'latitude': 37.419200897216797,

```

<sup>1</sup> GeoIP(R) is a registered trademark of MaxMind, LLC of Boston, Massachusetts.

```
'longitude': -122.05740356445312,
'postal_code': '94043',
'region': 'CA'}
>>> g.lat_lon('salon.com')
(37.789798736572266, -122.39420318603516)
>>> g.lon_lat('uh.edu')
(-95.415199279785156, 29.77549934387207)
>>> g.geos('24.124.1.80').wkt
'POINT (-95.2087020874023438 39.0392990112304688)'
```

## GeoIP Settings

### GEOIP\_PATH

A string specifying the directory where the GeoIP data files are located. This setting is *required* unless manually specified with `path` keyword when initializing the `GeoIP` object.

### GEOIP\_LIBRARY\_PATH

A string specifying the location of the GeoIP C library. Typically, this setting is only used if the GeoIP C library is in a non-standard location (e.g., `/home/sue/lib/libGeoIP.so`).

### GEOIP\_COUNTRY

The basename to use for the GeoIP country data file. Defaults to `'GeoIP.dat'`.

### GEOIP\_CITY

The basename to use for the GeoIP city data file. Defaults to `'GeoLiteCity.dat'`.

## GeoIP API

**class** `GeoIP` (*path=None, cache=0, country=None, city=None*)

The `GeoIP` object does not require any parameters to use the default settings. However, at the very least the `GEOIP_PATH` setting should be set with the path of the location of your GeoIP data sets. The following initialization keywords may be used to customize any of the defaults.

Keyword Arguments	Description
<code>path</code>	Base directory to where GeoIP data is located or the full path to where the city or country data files (.dat) are located. Assumes that both the city and country data sets are located in this directory; overrides the <code>GEOIP_PATH</code> settings attribute.
<code>cache</code>	The cache settings when opening up the GeoIP datasets, and may be an integer in (0, 1, 2, 4) corresponding to the <code>GEOIP_STANDARD</code> , <code>GEOIP_MEMORY_CACHE</code> , <code>GEOIP_CHECK_CACHE</code> , and <code>GEOIP_INDEX_CACHE</code> <code>GeoIPOptions</code> C API settings, respectively. Defaults to 0 ( <code>GEOIP_STANDARD</code> ).
<code>country</code>	The name of the GeoIP country data file. Defaults to <code>GeoIP.dat</code> . Setting this keyword overrides the <code>GEOIP_COUNTRY</code> settings attribute.
<code>city</code>	The name of the GeoIP city data file. Defaults to <code>GeoLiteCity.dat</code> . Setting this keyword overrides the <code>GEOIP_CITY</code> settings attribute.

## GeoIP Methods

### Querying

All the following querying routines may take either a string IP address or a fully qualified domain name (FQDN). For example, both `'205.186.163.125'` and `'djangoproject.com'` would be valid query parameters.

`GeoIP.city(query)`

Returns a dictionary of city information for the given query. Some of the values in the dictionary may be undefined (`None`).

`GeoIP.country(query)`

Returns a dictionary with the country code and country for the given query.

`GeoIP.country_code(query)`

Returns only the country code corresponding to the query.

`GeoIP.country_name(query)`

Returns only the country name corresponding to the query.

### Coordinate Retrieval

`GeoIP.coords(query)`

Returns a coordinate tuple of (longitude, latitude).

`GeoIP.lon_lat(query)`

Returns a coordinate tuple of (longitude, latitude).

`GeoIP.lat_lon(query)`

Returns a coordinate tuple of (latitude, longitude),

`GeoIP.geos(query)`

Returns a `django.contrib.gis.geos.Point` object corresponding to the query.

## Database Information

`GeoIP.country_info`

This property returns information about the GeoIP country database.

`GeoIP.city_info`

This property returns information about the GeoIP city database.

`GeoIP.info`

This property returns information about all GeoIP databases (both city and country), and the version of the GeoIP C library (if supported).

## GeoIP-Python API compatibility methods

These methods exist to ease compatibility with any code using MaxMind's existing Python API.

**classmethod** `GeoIP.open` (*path*, *cache*)

This classmethod instantiates the GeoIP object from the given database path and given cache setting.

`GeoIP.region_by_addr` (*query*)

`GeoIP.region_by_name` (*query*)

`GeoIP.record_by_addr` (*query*)

`GeoIP.record_by_name` (*query*)

`GeoIP.country_code_by_addr` (*query*)

`GeoIP.country_code_by_name` (*query*)

`GeoIP.country_name_by_addr` (*query*)

`GeoIP.country_name_by_name` (*query*)

## Geolocation with GeoIP2

The `GeoIP2` object is a wrapper for the [MaxMind geoip2 Python library](#).<sup>1</sup>

In order to perform IP-based geolocation, the `GeoIP2` object requires the [geoip2 Python library](#) and the [GeoIP Country and/or City datasets in binary format](#) (the CSV files will not work!). Grab the `GeoLite2-Country.mmdb.gz` and `GeoLite2-City.mmdb.gz` files and unzip them in a directory corresponding to the `GEOIP_PATH` setting.

Additionally, it is recommended to install the [libmaxminddb C library](#), so that `geoip2` can leverage the C library's faster speed.

## Example

Here is an example of its usage:

```
>>> from django.contrib.gis.geoip2 import GeoIP2
>>> g = GeoIP2()
>>> g.country('google.com')
{'country_code': 'US', 'country_name': 'United States'}
```

---

<sup>1</sup> GeoIP(R) is a registered trademark of MaxMind, Inc.

```
>>> g.city('72.14.207.99')
{'city': 'Mountain View',
 'country_code': 'US',
 'country_name': 'United States',
 'dma_code': 807,
 'latitude': 37.419200897216797,
 'longitude': -122.05740356445312,
 'postal_code': '94043',
 'region': 'CA'}
>>> g.lat_lon('salon.com')
(39.0437, -77.4875)
>>> g.lon_lat('uh.edu')
(-95.4342, 29.834)
>>> g.geos('24.124.1.80').wkt
'POINT (-97 38)'
```

## GeoIP Settings

### **GEOIP\_PATH**

A string specifying the directory where the GeoIP data files are located. This setting is *required* unless manually specified with `path` keyword when initializing the `GeoIP2` object.

### **GEOIP\_COUNTRY**

The basename to use for the GeoIP country data file. Defaults to `'GeoLite2-Country.mmdb'`.

### **GEOIP\_CITY**

The basename to use for the GeoIP city data file. Defaults to `'GeoLite2-City.mmdb'`.

## GeoIP API

**class GeoIP2** (*path=None, cache=0, country=None, city=None*)

The `GeoIP` object does not require any parameters to use the default settings. However, at the very least the `GEOIP_PATH` setting should be set with the path of the location of your GeoIP datasets. The following initialization keywords may be used to customize any of the defaults.

Keyword Arguments	Description
<code>path</code>	Base directory to where GeoIP data is located or the full path to where the city or country data files (.mddb) are located. Assumes that both the city and country datasets are located in this directory; overrides the <code>GEOIP_PATH</code> setting.
<code>cache</code>	The cache settings when opening up the GeoIP datasets. May be an integer in (0, 1, 2, 4, 8) corresponding to the <code>MODE_AUTO</code> , <code>MODE_MMAP_EXT</code> , <code>MODE_MMAP</code> , and <code>GEOIP_INDEX_CACHE</code> <code>MODE_MEMORY</code> C API settings, respectively. Defaults to 0 ( <code>MODE_AUTO</code> ).
<code>country</code>	The name of the GeoIP country data file. Defaults to <code>GeoLite2-Country.mddb</code> . Setting this keyword overrides the <code>GEOIP_COUNTRY</code> setting.
<code>city</code>	The name of the GeoIP city data file. Defaults to <code>GeoLite2-City.mddb</code> . Setting this keyword overrides the <code>GEOIP_CITY</code> setting.

## GeoIP Methods

### Instantiating

**classmethod** `GeoIP2.open` (*path*, *cache*)

This classmethod instantiates the GeoIP object from the given database path and given cache setting.

### Querying

All the following querying routines may take either a string IP address or a fully qualified domain name (FQDN). For example, both `'205.186.163.125'` and `'djangoproject.com'` would be valid query parameters.

`GeoIP2.city` (*query*)

Returns a dictionary of city information for the given query. Some of the values in the dictionary may be undefined (`None`).

`GeoIP2.country` (*query*)

Returns a dictionary with the country code and country for the given query.

`GeoIP2.country_code` (*query*)

Returns the country code corresponding to the query.

`GeoIP2.country_name` (*query*)

Returns the country name corresponding to the query.

### Coordinate Retrieval

`GeoIP2.coords` (*query*)

Returns a coordinate tuple of (longitude, latitude).

`GeoIP2.lon_lat` (*query*)

Returns a coordinate tuple of (longitude, latitude).

`GeoIP2.lat_lon` (*query*)

Returns a coordinate tuple of (latitude, longitude),

GeoIP2.`geos` (*query*)

Returns a `Point` object corresponding to the query.

## GeoDjango Utilities

The `django.contrib.gis.utils` module contains various utilities that are useful in creating geospatial Web applications.

### LayerMapping data import utility

The `LayerMapping` class provides a way to map the contents of vector spatial data files (e.g. shapefiles) into GeoDjango models.

This utility grew out of the author's personal needs to eliminate the code repetition that went into pulling geometries and fields out of a vector layer, converting to another coordinate system (e.g. WGS84), and then inserting into a GeoDjango model.

---

**Note:** Use of `LayerMapping` requires GDAL.

---

**Warning:** GIS data sources, like shapefiles, may be very large. If you find that `LayerMapping` is using too much memory, set `DEBUG` to `False` in your settings. When `DEBUG` is set to `True`, Django *automatically logs every SQL query* – thus, when SQL statements contain geometries, it is easy to consume more memory than is typical.

## Example

1. You need a GDAL-supported data source, like a shapefile (here we're using a simple polygon shapefile, `test_poly.shp`, with three features):

```
>>> from django.contrib.gis.gdal import DataSource
>>> ds = DataSource('test_poly.shp')
>>> layer = ds[0]
>>> print(layer.fields) # Exploring the fields in the layer, we only want the 'str
→' field.
['float', 'int', 'str']
>>> print(len(layer)) # getting the number of features in the layer (should be 3)
3
>>> print(layer.geom_type) # Should be 'Polygon'
Polygon
>>> print(layer.srs) # WGS84 in WKT
GEOGCS["GCS_WGS_1984",
    DATUM["WGS_1984",
        SPHEROID["WGS_1984",6378137,298.257223563]],
    PRIMEM["Greenwich",0],
    UNIT["Degree",0.017453292519943295]]
```

2. Now we define our corresponding Django model (make sure to use `migrate`):

```

from django.contrib.gis.db import models

class TestGeo(models.Model):
    name = models.CharField(max_length=25) # corresponds to the 'str' field
    poly = models.PolygonField(srid=4269) # we want our model in a different SRID

    def __str__(self):
        # __unicode__ on Python 2
        return 'Name: %s' % self.name

```

3. Use *LayerMapping* to extract all the features and place them in the database:

```

>>> from django.contrib.gis.utils import LayerMapping
>>> from geoapp.models import TestGeo
>>> mapping = {'name' : 'str', # The 'name' model field maps to the 'str' layer_
↳field.
                'poly' : 'POLYGON', # For geometry fields use OGC name.
            } # The mapping is a dictionary
>>> lm = LayerMapping(TestGeo, 'test_poly.shp', mapping)
>>> lm.save(verbose=True) # Save the layermap, imports the data.
Saved: Name: 1
Saved: Name: 2
Saved: Name: 3

```

Here, *LayerMapping* just transformed the three geometries from the shapefile in their original spatial reference system (WGS84) to the spatial reference system of the GeoDjango model (NAD83). If no spatial reference system is defined for the layer, use the `source_srs` keyword with a *SpatialReference* object to specify one.

### LayerMapping API

```

class LayerMapping(model, data_source, mapping, layer=0, source_srs=None, encoding=None, transaction_mode='commit_on_success', transform=True, unique=True, using='default')

```

The following are the arguments and keywords that may be used during instantiation of *LayerMapping* objects.

Argument	Description
<code>model</code>	The geographic model, <i>not</i> an instance.
<code>data_source</code>	The path to the OGR-supported data source file (e.g., a shapefile). Also accepts <i>django.contrib.gis.gdal.DataSource</i> instances.
<code>mapping</code>	A dictionary: keys are strings corresponding to the model field, and values correspond to string field names for the OGR feature, or if the model field is a geographic then it should correspond to the OGR geometry type, e.g., 'POINT', 'LINESTRING', 'POLYGON'.

Keyword Arguments	
<code>layer</code>	The index of the layer to use from the Data Source (defaults to 0)
<code>source_srs</code>	Use this to specify the source SRS manually (for example, some shapefiles don't come with a '.prj' file). An integer SRID, WKT or PROJ.4 strings, and <code>django.contrib.gis.gdal.SpatialReference</code> objects are accepted.
<code>encoding</code>	Specifies the character set encoding of the strings in the OGR data source. For example, 'latin-1', 'utf-8', and 'cp437' are all valid encoding parameters.
<code>transaction_mode</code>	May be 'commit_on_success' (default) or 'autocommit'.
<code>transform</code>	Setting this to False will disable coordinate transformations. In other words, geometries will be inserted into the database unmodified from their original state in the data source.
<code>unique</code>	Setting this to the name, or a tuple of names, from the given model will create models unique only to the given name(s). Geometries from each feature will be added into the collection associated with the unique model. Forces the transaction mode to be 'autocommit'.
<code>using</code>	Sets the database to use when importing spatial data. Default is 'default'.

### save () Keyword Arguments

`LayerMapping.save(verbose=False, fid_range=False, step=False, progress=False, silent=False, stream=sys.stdout, strict=False)`

The `save ()` method also accepts keywords. These keywords are used for controlling output logging, error handling, and for importing specific feature ranges.

Save Keyword Arguments	Description
<code>fid_range</code>	May be set with a slice or tuple of (begin, end) feature ID's to map from the data source. In other words, this keyword enables the user to selectively import a subset range of features in the geographic data source.
<code>progress</code>	When this keyword is set, status information will be printed giving the number of features processed and successfully saved. By default, progress information will be printed every 1000 features processed, however, this default may be overridden by setting this keyword with an integer for the desired interval.
<code>silent</code>	By default, non-fatal error notifications are printed to <code>sys.stdout</code> , but this keyword may be set to disable these notifications.
<code>step</code>	If set with an integer, transactions will occur at every step interval. For example, if <code>step=1000</code> , a commit would occur after the 1,000th feature, the 2,000th feature etc.
<code>stream</code>	Status information will be written to this file handle. Defaults to using <code>sys.stdout</code> , but any object with a <code>write</code> method is supported.
<code>strict</code>	Execution of the model mapping will cease upon the first error encountered. The default value (False) behavior is to attempt to continue.
<code>verbose</code>	If set, information will be printed subsequent to each model save executed on the database.

## Troubleshooting

### Running out of memory

As noted in the warning at the top of this section, Django stores all SQL queries when `DEBUG=True`. Set `DEBUG=False` in your settings, and this should stop excessive memory use when running `LayerMapping` scripts.

## MySQL: max\_allowed\_packet error

If you encounter the following error when using LayerMapping and MySQL:

```
OperationalError: (1153, "Got a packet bigger than 'max_allowed_packet' bytes")
```

Then the solution is to increase the value of the `max_allowed_packet` setting in your MySQL configuration. For example, the default value may be something low like one megabyte – the setting may be modified in MySQL's configuration file (`my.cnf`) in the `[mysqld]` section:

```
max_allowed_packet = 10M
```

## OGR Inspection

### `ogrinspect`

`ogrinspect` (*data\_source*, *model\_name*, *\*\*kwargs*)

### `mapping`

`mapping` (*data\_source*, *geom\_name='geom'*, *layer\_key=0*, *multi\_geom=False*)

## GeoJSON Serializer

GeoDjango provides a specific serializer for the GeoJSON format. See *Serializing Django objects* for more information on serialization.

The GDAL library is required if any of the serialized geometries need coordinate transformations (that is if the geometry's spatial reference system differs from the `srid` serializer option).

The GeoJSON serializer no longer needs GDAL if all geometries are in the same coordinate system as the `srid` serializer option.

The `geojson` serializer is not meant for round-tripping data, as it has no deserializer equivalent. For example, you cannot use `loaddata` to reload the output produced by this serializer. If you plan to reload the outputted data, use the plain `json serializer` instead.

In addition to the options of the `json` serializer, the `geojson` serializer accepts the following additional option when it is called by `serializers.serialize()`:

- `geometry_field`: A string containing the name of a geometry field to use for the `geometry` key of the GeoJSON feature. This is only needed when you have a model with more than one geometry field and you don't want to use the first defined geometry field (by default, the first geometry field is picked).
- `srid`: The SRID to use for the geometry content. Defaults to 4326 (WGS 84).

The `fields` option can be used to limit fields that will be present in the `properties` key, as it works with all other serializers.

Example:

```
from django.core.serializers import serialize
from my_app.models import City

serialize('geojson', City.objects.all(),
```

```
geometry_field='point',
fields=('name',))
```

Would output:

```
{
  'type': 'FeatureCollection',
  'crs': {
    'type': 'name',
    'properties': {'name': 'EPSG:4326'}
  },
  'features': [
    {
      'type': 'Feature',
      'geometry': {
        'type': 'Point',
        'coordinates': [-87.650175, 41.850385]
      },
      'properties': {
        'name': 'Chicago'
      }
    }
  ]
}
```

When the `fields` parameter is not specified, the `geojson` serializer adds a `pk` key to the `properties` dictionary with the primary key of the object as the value.

The `pk` key was added to the `properties` dictionary.

## GeoDjango Management Commands

### `inspectdb`

#### `django-admin inspectdb`

When `django.contrib.gis` is in your `INSTALLED_APPS`, the `inspectdb` management command is overridden with one from GeoDjango. The overridden command is spatially-aware, and places geometry fields in the auto-generated model definition, where appropriate.

### `ogrinspect`

#### `django-admin ogrinspect data_source model_name`

The `ogrinspect` management command will inspect the given OGR-compatible `DataSource` (e.g., a shapefile) and will output a GeoDjango model with the given model name. There's a detailed example of using `ogrinspect` *in the tutorial*.

#### `--blank` BLANK

Use a comma separated list of OGR field names to add the `blank=True` keyword option to the field definition. Set with `true` to apply to all applicable fields.

#### `--decimal` DECIMAL

Use a comma separated list of OGR float fields to generate `DecimalField` instead of the default `FloatField`. Set to `true` to apply to all OGR float fields.

- geom-name** GEOM\_NAME  
Specifies the model attribute name to use for the geometry field. Defaults to 'geom'.
- layer** LAYER\_KEY  
The key for specifying which layer in the OGR *DataSource* source to use. Defaults to 0 (the first layer). May be an integer or a string identifier for the *Layer*. When inspecting databases, *layer* is generally the table name you want to inspect.
- mapping**  
Automatically generate a mapping dictionary for use with *LayerMapping*.
- multi-geom**  
When generating the geometry field, treat it as a geometry collection. For example, if this setting is enabled then a *MultiPolygonField* will be placed in the generated model rather than *PolygonField*.
- name-field** NAME\_FIELD  
Generates a `__str__` routine (`__unicode__` on Python 2) on the model that will return the given field name.
- no-imports**  
Suppresses the `from django.contrib.gis.db import models` import statement.
- null** NULL  
Use a comma separated list of OGR field names to add the `null=True` keyword option to the field definition. Set with `true` to apply to all applicable fields.
- srid** SRID  
The SRID to use for the geometry field. If not set, `ogrinspect` attempts to automatically determine of the SRID of the data source.

## GeoDjango's admin site

### GeoModelAdmin

class `GeoModelAdmin`

`default_lon`

The default center longitude.

`default_lat`

The default center latitude.

`default_zoom`

The default zoom level to use. Defaults to 18.

`extra_js`

Sequence of URLs to any extra JavaScript to include.

`map_template`

Override the template used to generate the JavaScript slippy map. Default is 'gis/admin/openlayers.html'.

`map_width`

Width of the map, in pixels. Defaults to 600.

`map_height`

Height of the map, in pixels. Defaults to 400.

**openlayers\_url**

Link to the URL of the OpenLayers JavaScript. Defaults to 'http://openlayers.org/api/2.13.1/OpenLayers.js'.

**modifiable**

Defaults to True. When set to False, disables editing of existing geometry fields in the admin.

---

**Note:** This is different from adding the geometry field to *readonly\_fields*, which will only display the WKT of the geometry. Setting `modifiable=False`, actually displays the geometry in a map, but disables the ability to edit its vertices.

---

**OSMGeoAdmin****class OSMGeoAdmin**

A subclass of *GeoModelAdmin* that uses a spherical mercator projection with *OpenStreetMap* street data tiles. See the *OSMGeoAdmin introduction* in the tutorial for a usage example.

**Geographic Feeds**

GeoDjango has its own *Feed* subclass that may embed location information in RSS/Atom feeds formatted according to either the *Simple GeoRSS* or *W3C Geo* standards. Because GeoDjango's syndication API is a superset of Django's, please consult *Django's syndication documentation* for details on general usage.

**Example****API Reference****Feed Subclass****class Feed**

In addition to methods provided by the *django.contrib.syndication.views.Feed* base class, GeoDjango's *Feed* class provides the following overrides. Note that these overrides may be done in multiple ways:

```
from django.contrib.gis.feeds import Feed

class MyFeed(Feed):

    # First, as a class attribute.
    geometry = ...
    item_geometry = ...

    # Also a function with no arguments
    def geometry(self):
        ...

    def item_geometry(self):
        ...
```

```
# And as a function with a single argument
def geometry(self, obj):
    ...

def item_geometry(self, item):
    ...
```

#### **geometry** (*obj*)

Takes the object returned by `get_object()` and returns the *feed's* geometry. Typically this is a `GEOSGeometry` instance, or can be a tuple to represent a point or a box. For example:

```
class ZipcodeFeed(Feed):

    def geometry(self, obj):
        # Can also return: `obj.poly`, and `obj.poly.centroid`.
        return obj.poly.extent # tuple like: (X0, Y0, X1, Y1).
```

#### **item\_geometry** (*item*)

Set this to return the geometry for each *item* in the feed. This can be a `GEOSGeometry` instance, or a tuple that represents a point coordinate or bounding box. For example:

```
class ZipcodeFeed(Feed):

    def item_geometry(self, obj):
        # Returns the polygon.
        return obj.poly
```

## SyndicationFeed Subclasses

The following `django.utils.feedgenerator.SyndicationFeed` subclasses are available:

```
class GeoRSSFeed
```

```
class GeoAtom1Feed
```

```
class W3CGeoFeed
```

---

**Note:** W3C Geo formatted feeds only support `PointField` geometries.

---

## Geographic Sitemaps

KML is an XML language focused on geographic visualization<sup>1</sup>. `KMLSiteMap` and its compressed counterpart `KMZSiteMap` allow you to present geolocated data in a machine-readable format.

---

<sup>1</sup> <http://www.opengeospatial.org/standards/kml>

## Example

## Reference

[KML Sitemap](#)

[KMZ Sitemap](#)

## Testing GeoDjango apps

Included in this documentation are some additional notes and settings for *PostGIS* users.

## PostGIS

### Settings

---

**Note:** The settings below have sensible defaults, and shouldn't require manual setting.

---

#### POSTGIS\_VERSION

When GeoDjango's spatial backend initializes on PostGIS, it has to perform an SQL query to determine the version in order to figure out what features are available. Advanced users wishing to prevent this additional query may set the version manually using a 3-tuple of integers specifying the major, minor, and micro version numbers for PostGIS. For example, to configure for PostGIS X.Y.Z you would use:

```
POSTGIS_VERSION = (X, Y, Z)
```

### Obtaining sufficient privileges

Depending on your configuration, this section describes several methods to configure a database user with sufficient privileges to run tests for GeoDjango applications on PostgreSQL. If your *spatial database template* was created like in the instructions, then your testing database user only needs to have the ability to create databases. In other configurations, you may be required to use a database superuser.

#### Create database user

To make a database user with the ability to create databases, use the following command:

```
$ createuser --createdb -R -S <user_name>
```

The `-R -S` flags indicate that we do not want the user to have the ability to create additional users (roles) or to be a superuser, respectively.

Alternatively, you may alter an existing user's role from the SQL shell (assuming this is done from an existing superuser account):

```
postgres# ALTER ROLE <user_name> CREATEDB NOSUPERUSER NOCREATEROLE;
```

## Create database superuser

This may be done at the time the user is created, for example:

```
$ createuser --superuser <user_name>
```

Or you may alter the user's role from the SQL shell (assuming this is done from an existing superuser account):

```
postgres# ALTER ROLE <user_name> SUPERUSER;
```

## Windows

On Windows platforms the pgAdmin III utility may also be used as a simple way to add superuser privileges to your database user.

By default, the PostGIS installer on Windows includes a template spatial database entitled `template_postgis`.

## GeoDjango tests

To have the GeoDjango tests executed when *running the Django test suite* with `runtests.py` all of the databases in the settings file must be using one of the *spatial database backends*.

## Example

The following is an example bare-bones settings file with spatial backends that can be used to run the entire Django test suite, including those in *django.contrib.gis*:

```
DATABASES = {
    'default': {
        'ENGINE': 'django.contrib.gis.db.backends.postgis',
        'NAME': 'geodjango',
        'USER': 'geodjango',
    },
    'other': {
        'ENGINE': 'django.contrib.gis.db.backends.postgis',
        'NAME': 'other',
        'USER': 'geodjango',
    },
}

SECRET_KEY = 'django_tests_secret_key'
```

Assuming the settings above were in a `postgis.py` file in the same directory as `runtests.py`, then all Django and GeoDjango tests would be performed when executing the command:

```
$ ./runtests.py --settings=postgis
```

To run only the GeoDjango test suite, specify `gis_tests`:

```
$ ./runtests.py --settings=postgis gis_tests
```

## Deploying GeoDjango

Basically, the deployment of a GeoDjango application is not different from the deployment of a normal Django application. Please consult Django's *deployment documentation*.

**Warning:** GeoDjango uses the GDAL geospatial library which is not thread safe at this time. Thus, it is *highly* recommended to not use threading when deploying – in other words, use an appropriate configuration of Apache.

For example, when configuring your application with `mod_wsgi`, set the `WSGIDaemonProcess` attribute `threads` to 1, unless Apache may crash when running your GeoDjango application. Increase the number of processes instead.

### 6.5.6 `django.contrib.humanize`

A set of Django template filters useful for adding a “human touch” to data.

To activate these filters, add `'django.contrib.humanize'` to your `INSTALLED_APPS` setting. Once you've done that, use `{% load humanize %}` in a template, and you'll have access to the following filters.

#### `apnumber`

For numbers 1-9, returns the number spelled out. Otherwise, returns the number. This follows Associated Press style.

Examples:

- 1 becomes one.
- 2 becomes two.
- 10 becomes 10.

You can pass in either an integer or a string representation of an integer.

#### `intcomma`

Converts an integer or float (or a string representation of either) to a string containing commas every three digits.

Examples:

- 4500 becomes 4,500.
- 4500.2 becomes 4,500.2.
- 45000 becomes 45,000.
- 450000 becomes 450,000.
- 4500000 becomes 4,500,000.

*Format localization* will be respected if enabled, e.g. with the `'de'` language:

- 45000 becomes `'45.000'`.
- 450000 becomes `'450.000'`.

### `intword`

Converts a large integer (or a string representation of an integer) to a friendly text representation. Works best for numbers over 1 million.

Examples:

- 1000000 becomes 1.0 million.
- 1200000 becomes 1.2 million.
- 1200000000 becomes 1.2 billion.

Values up to  $10^{100}$  (Googol) are supported.

*Format localization* will be respected if enabled, e.g. with the 'de' language:

- 1000000 becomes '1,0 Million'.
- 1200000 becomes '1,2 Million'.
- 1200000000 becomes '1,2 Milliarden'.

### `naturalday`

For dates that are the current day or within one day, return “today”, “tomorrow” or “yesterday”, as appropriate. Otherwise, format the date using the passed in format string.

**Argument:** Date formatting string as described in the *date* tag.

Examples (when ‘today’ is 17 Feb 2007):

- 16 Feb 2007 becomes yesterday.
- 17 Feb 2007 becomes today.
- 18 Feb 2007 becomes tomorrow.
- Any other day is formatted according to given argument or the *DATE\_FORMAT* setting if no argument is given.

### `naturaltime`

For datetime values, returns a string representing how many seconds, minutes or hours ago it was – falling back to the *timesince* format if the value is more than a day old. In case the datetime value is in the future the return value will automatically use an appropriate phrase.

Examples (when ‘now’ is 17 Feb 2007 16:30:00):

- 17 Feb 2007 16:30:00 becomes now.
- 17 Feb 2007 16:29:31 becomes 29 seconds ago.
- 17 Feb 2007 16:29:00 becomes a minute ago.
- 17 Feb 2007 16:25:35 becomes 4 minutes ago.
- 17 Feb 2007 15:30:29 becomes 59 minutes ago.
- 17 Feb 2007 15:30:01 becomes 59 minutes ago.
- 17 Feb 2007 15:30:00 becomes an hour ago.
- 17 Feb 2007 13:31:29 becomes 2 hours ago.
- 16 Feb 2007 13:31:29 becomes 1 day, 2 hours ago.

- 16 Feb 2007 13:30:01 becomes 1 day, 2 hours ago.
- 16 Feb 2007 13:30:00 becomes 1 day, 3 hours ago.
- 17 Feb 2007 16:30:30 becomes 30 seconds from now.
- 17 Feb 2007 16:30:29 becomes 29 seconds from now.
- 17 Feb 2007 16:31:00 becomes a minute from now.
- 17 Feb 2007 16:34:35 becomes 4 minutes from now.
- 17 Feb 2007 17:30:29 becomes an hour from now.
- 17 Feb 2007 18:31:29 becomes 2 hours from now.
- 18 Feb 2007 16:31:29 becomes 1 day from now.
- 26 Feb 2007 18:31:29 becomes 1 week, 2 days from now.

### ordinal

Converts an integer to its ordinal as a string.

Examples:

- 1 becomes 1st.
- 2 becomes 2nd.
- 3 becomes 3rd.

You can pass in either an integer or a string representation of an integer.

## 6.5.7 The messages framework

Quite commonly in web applications, you need to display a one-time notification message (also known as “flash message”) to the user after processing a form or some other types of user input.

For this, Django provides full support for cookie- and session-based messaging, for both anonymous and authenticated users. The messages framework allows you to temporarily store messages in one request and retrieve them for display in a subsequent request (usually the next one). Every message is tagged with a specific `level` that determines its priority (e.g., `info`, `warning`, or `error`).

### Enabling messages

Messages are implemented through a *middleware* class and corresponding *context processor*.

The default `settings.py` created by `django-admin startproject` already contains all the settings required to enable message functionality:

- `'django.contrib.messages'` is in `INSTALLED_APPS`.
- `MIDDLEWARE` contains `'django.contrib.sessions.middleware.SessionMiddleware'` and `'django.contrib.messages.middleware.MessageMiddleware'`.

The default *storage backend* relies on *sessions*. That’s why `SessionMiddleware` must be enabled and appear before `MessageMiddleware` in `MIDDLEWARE`.

- The `'context_processors'` option of the DjangoTemplates backend defined in your `TEMPLATES` setting contains `'django.contrib.messages.context_processors.messages'`.

If you don't want to use messages, you can remove `'django.contrib.messages'` from your `INSTALLED_APPS`, the `MessageMiddleware` line from `MIDDLEWARE`, and the messages context processor from `TEMPLATES`.

## Configuring the message engine

### Storage backends

The messages framework can use different backends to store temporary messages.

Django provides three built-in storage classes in `django.contrib.messages`:

**class** `storage.session.SessionStorage`

This class stores all messages inside of the request's session. Therefore it requires Django's `contrib.sessions` application.

**class** `storage.cookie.CookieStorage`

This class stores the message data in a cookie (signed with a secret hash to prevent manipulation) to persist notifications across requests. Old messages are dropped if the cookie data size would exceed 2048 bytes.

**class** `storage.fallback.FallbackStorage`

This class first uses `CookieStorage`, and falls back to using `SessionStorage` for the messages that could not fit in a single cookie. It also requires Django's `contrib.sessions` application.

This behavior avoids writing to the session whenever possible. It should provide the best performance in the general case.

`FallbackStorage` is the default storage class. If it isn't suitable to your needs, you can select another storage class by setting `MESSAGE_STORAGE` to its full import path, for example:

```
MESSAGE_STORAGE = 'django.contrib.messages.storage.cookie.CookieStorage'
```

**class** `storage.base.BaseStorage`

To write your own storage class, subclass the `BaseStorage` class in `django.contrib.messages.storage.base` and implement the `_get` and `_store` methods.

## Message levels

The messages framework is based on a configurable level architecture similar to that of the Python logging module. Message levels allow you to group messages by type so they can be filtered or displayed differently in views and templates.

The built-in levels, which can be imported from `django.contrib.messages` directly, are:

Constant	Purpose
<code>DEBUG</code>	Development-related messages that will be ignored (or removed) in a production deployment
<code>INFO</code>	Informational messages for the user
<code>SUCCESS</code>	An action was successful, e.g. "Your profile was updated successfully"
<code>WARNING</code>	A failure did not occur but may be imminent
<code>ERROR</code>	An action was <b>not</b> successful or some other failure occurred

The `MESSAGE_LEVEL` setting can be used to change the minimum recorded level (or it can be *changed per request*). Attempts to add messages of a level less than this will be ignored.

## Message tags

Message tags are a string representation of the message level plus any extra tags that were added directly in the view (see *Adding extra message tags* below for more details). Tags are stored in a string and are separated by spaces. Typically, message tags are used as CSS classes to customize message style based on message type. By default, each level has a single tag that's a lowercase version of its own constant:

Level Constant	Tag
DEBUG	debug
INFO	info
SUCCESS	success
WARNING	warning
ERROR	error

To change the default tags for a message level (either built-in or custom), set the `MESSAGE_TAGS` setting to a dictionary containing the levels you wish to change. As this extends the default tags, you only need to provide tags for the levels you wish to override:

```
from django.contrib.messages import constants as messages
MESSAGE_TAGS = {
    messages.INFO: '',
    50: 'critical',
}
```

## Using messages in views and templates

`add_message` (*request*, *level*, *message*, *extra\_tags*='', *fail\_silently*=False)

### Adding a message

To add a message, call:

```
from django.contrib import messages
messages.add_message(request, messages.INFO, 'Hello world.')
```

Some shortcut methods provide a standard way to add messages with commonly used tags (which are usually represented as HTML classes for the message):

```
messages.debug(request, '%s SQL statements were executed.' % count)
messages.info(request, 'Three credits remain in your account.')
messages.success(request, 'Profile details updated.')
messages.warning(request, 'Your account expires in three days.')
messages.error(request, 'Document deleted.')
```

## Displaying messages

`get_messages` (*request*)

In your template, use something like:

```
{% if messages %}
<ul class="messages">
  {% for message in messages %}
```

```
<li{% if message.tags %} class="{{ message.tags }}"{% endif %}>{{ message }}</li>
{% endfor %}
</ul>
{% endif %}
```

If you're using the context processor, your template should be rendered with a `RequestContext`. Otherwise, ensure `messages` is available to the template context.

Even if you know there is only just one message, you should still iterate over the `messages` sequence, because otherwise the message storage will not be cleared for the next request.

The context processor also provides a `DEFAULT_MESSAGE_LEVELS` variable which is a mapping of the message level names to their numeric value:

```
{% if messages %}
<ul class="messages">
  {% for message in messages %}
    <li{% if message.tags %} class="{{ message.tags }}"{% endif %}>
      {% if message.level == DEFAULT_MESSAGE_LEVELS.ERROR %}Important: {% endif %}
      {{ message }}
    </li>
  {% endfor %}
</ul>
{% endif %}
```

Outside of templates, you can use `get_messages()`:

```
from django.contrib.messages import get_messages

storage = get_messages(request)
for message in storage:
    do_something_with_the_message(message)
```

For instance, you can fetch all the messages to return them in a `JSONResponseMixin` instead of a `TemplateResponseMixin`.

`get_messages()` will return an instance of the configured storage backend.

## The Message class

**class** `storage.base.Message`

When you loop over the list of messages in a template, what you get are instances of the `Message` class. It's quite a simple object, with only a few attributes:

- `message`: The actual text of the message.
- `level`: An integer describing the type of the message (see the *message levels* section above).
- `tags`: A string combining all the message's tags (`extra_tags` and `level_tag`) separated by spaces.
- `extra_tags`: A string containing custom tags for this message, separated by spaces. It's empty by default.
- `level_tag`: The string representation of the level. By default, it's the lowercase version of the name of the associated constant, but this can be changed if you need by using the `MESSAGE_TAGS` setting.

## Creating custom message levels

Messages levels are nothing more than integers, so you can define your own level constants and use them to create more customized user feedback, e.g.:

```
CRITICAL = 50

def my_view(request):
    messages.add_message(request, CRITICAL, 'A serious error occurred.')
```

When creating custom message levels you should be careful to avoid overloading existing levels. The values for the

Level Constant	Value
DEBUG	10
INFO	20
SUCCESS	25
WARNING	30
ERROR	40

built-in levels are:

If you need to identify the custom levels in your HTML or CSS, you need to provide a mapping via the `MESSAGE_TAGS` setting.

**Note:** If you are creating a reusable application, it is recommended to use only the built-in *message levels* and not rely on any custom levels.

## Changing the minimum recorded level per-request

The minimum recorded level can be set per request via the `set_level` method:

```
from django.contrib import messages

# Change the messages level to ensure the debug message is added.
messages.set_level(request, messages.DEBUG)
messages.debug(request, 'Test message...')

# In another request, record only messages with a level of WARNING and higher
messages.set_level(request, messages.WARNING)
messages.success(request, 'Your profile was updated.') # ignored
messages.warning(request, 'Your account is about to expire.') # recorded

# Set the messages level back to default.
messages.set_level(request, None)
```

Similarly, the current effective level can be retrieved with `get_level`:

```
from django.contrib import messages
current_level = messages.get_level(request)
```

For more information on how the minimum recorded level functions, see *Message levels* above.

## Adding extra message tags

For more direct control over message tags, you can optionally provide a string containing extra tags to any of the add methods:

```
messages.add_message(request, messages.INFO, 'Over 9000!', extra_tags='dragonball')
messages.error(request, 'Email box full', extra_tags='email')
```

Extra tags are added before the default tag for that level and are space separated.

### Failing silently when the message framework is disabled

If you're writing a reusable app (or other piece of code) and want to include messaging functionality, but don't want to require your users to enable it if they don't want to, you may pass an additional keyword argument `fail_silently=True` to any of the `add_message` family of methods. For example:

```
messages.add_message(
    request, messages.SUCCESS, 'Profile details updated.',
    fail_silently=True,
)
messages.info(request, 'Hello world.', fail_silently=True)
```

---

**Note:** Setting `fail_silently=True` only hides the `MessageFailure` that would otherwise occur when the messages framework disabled and one attempts to use one of the `add_message` family of methods. It does not hide failures that may occur for other reasons.

---

### Adding messages in class-based views

#### `class` `views.SuccessMessageMixin`

Adds a success message attribute to *FormView* based classes

#### `get_success_message` (*cleaned\_data*)

*cleaned\_data* is the cleaned data from the form which is used for string formatting

#### Example views.py:

```
from django.contrib.messages.views import SuccessMessageMixin
from django.views.generic.edit import CreateView
from myapp.models import Author

class AuthorCreate(SuccessMessageMixin, CreateView):
    model = Author
    success_url = '/success/'
    success_message = "%(name)s was created successfully"
```

The cleaned data from the form is available for string interpolation using the `%(field_name)s` syntax. For `ModelForms`, if you need access to fields from the saved object override the `get_success_message()` method.

#### Example views.py for `ModelForms`:

```
from django.contrib.messages.views import SuccessMessageMixin
from django.views.generic.edit import CreateView
from myapp.models import ComplicatedModel

class ComplicatedCreate(SuccessMessageMixin, CreateView):
    model = ComplicatedModel
    success_url = '/success/'
    success_message = "%(calculated_field)s was created successfully"
```

```
def get_success_message(self, cleaned_data):
    return self.success_message % dict(
        cleaned_data,
        calculated_field=self.object.calculated_field,
    )
```

## Expiration of messages

The messages are marked to be cleared when the storage instance is iterated (and cleared when the response is processed).

To avoid the messages being cleared, you can set the messages storage to `False` after iterating:

```
storage = messages.get_messages(request)
for message in storage:
    do_something_with(message)
storage.used = False
```

## Behavior of parallel requests

Due to the way cookies (and hence sessions) work, **the behavior of any backends that make use of cookies or sessions is undefined when the same client makes multiple requests that set or get messages in parallel**. For example, if a client initiates a request that creates a message in one window (or tab) and then another that fetches any uniterated messages in another window, before the first window redirects, the message may appear in the second window instead of the first window where it may be expected.

In short, when multiple simultaneous requests from the same client are involved, messages are not guaranteed to be delivered to the same window that created them nor, in some cases, at all. Note that this is typically not a problem in most applications and will become a non-issue in HTML5, where each window/tab will have its own browsing context.

## Settings

A few *settings* give you control over message behavior:

- `MESSAGE_LEVEL`
- `MESSAGE_STORAGE`
- `MESSAGE_TAGS`

For backends that use cookies, the settings for the cookie are taken from the session cookie settings:

- `SESSION_COOKIE_DOMAIN`
- `SESSION_COOKIE_SECURE`
- `SESSION_COOKIE_HTTPONLY`

## 6.5.8 django.contrib.postgres

PostgreSQL has a number of features which are not shared by the other databases Django supports. This optional module contains model fields and form fields for a number of PostgreSQL specific data types.

Psycopg2 2.5 or higher is required, though we highly recommend using the latest release. Some fields require higher versions.

---

**Note:** Django is, and will continue to be, a database-agnostic web framework. We would encourage those writing reusable applications for the Django community to write database-agnostic code where practical. However, we recognize that real world projects written using Django need not be database-agnostic. In fact, once a project reaches a given size changing the underlying data store is already a significant challenge and is likely to require changing the code base in some ways to handle differences between the data stores.

Django provides support for a number of data types which will only work with PostgreSQL. There is no fundamental reason why (for example) a `contrib.mysql` module does not exist, except that PostgreSQL has the richest feature set of the supported databases so its users have the most to gain.

---

### PostgreSQL specific aggregation functions

These functions are described in more detail in the [PostgreSQL docs](#).

---

**Note:** All functions come without default aliases, so you must explicitly provide one. For example:

```
>>> SomeModel.objects.aggregate(arr=ArrayAgg('somefield'))
{'arr': [0, 1, 2]}
```

---

### General-purpose aggregation functions

#### ArrayAgg

**class** `ArrayAgg` (*expression*, *\*\*extra*)

Returns a list of values, including nulls, concatenated into an array.

#### BitAnd

**class** `BitAnd` (*expression*, *\*\*extra*)

Returns an `int` of the bitwise AND of all non-null input values, or `None` if all values are null.

#### BitOr

**class** `BitOr` (*expression*, *\*\*extra*)

Returns an `int` of the bitwise OR of all non-null input values, or `None` if all values are null.

#### BoolAnd

**class** `BoolAnd` (*expression*, *\*\*extra*)

Returns `True`, if all input values are true, `None` if all values are null or if there are no values, otherwise `False`.

## BoolOr

**class BoolOr** (*expression*, *\*\*extra*)

Returns True if at least one input value is true, None if all values are null or if there are no values, otherwise False.

## StringAgg

**class StringAgg** (*expression*, *delimiter*)

Returns the input values concatenated into a string, separated by the `delimiter` string.

**delimiter**

Required argument. Needs to be a string.

## Aggregate functions for statistics

### y and x

The arguments `y` and `x` for all these functions can be the name of a field or an expression returning a numeric data. Both are required.

## Corr

**class Corr** (*y*, *x*)

Returns the correlation coefficient as a `float`, or None if there aren't any matching rows.

## CovarPop

**class CovarPop** (*y*, *x*, *sample=False*)

Returns the population covariance as a `float`, or None if there aren't any matching rows.

Has one optional argument:

**sample**

By default `CovarPop` returns the general population covariance. However, if `sample=True`, the return value will be the sample population covariance.

## RegrAvgX

**class RegrAvgX** (*y*, *x*)

Returns the average of the independent variable ( $\text{sum}(x) / N$ ) as a `float`, or None if there aren't any matching rows.

## RegrAvgY

**class RegrAvgY** (*y*, *x*)

Returns the average of the dependent variable ( $\text{sum}(y) / N$ ) as a `float`, or None if there aren't any matching rows.

### RegrCount

**class** **RegrCount** (*y, x*)

Returns an `int` of the number of input rows in which both expressions are not null.

### RegrIntercept

**class** **RegrIntercept** (*y, x*)

Returns the y-intercept of the least-squares-fit linear equation determined by the (*x*, *y*) pairs as a `float`, or `None` if there aren't any matching rows.

### RegrR2

**class** **RegrR2** (*y, x*)

Returns the square of the correlation coefficient as a `float`, or `None` if there aren't any matching rows.

### RegrSlope

**class** **RegrSlope** (*y, x*)

Returns the slope of the least-squares-fit linear equation determined by the (*x*, *y*) pairs as a `float`, or `None` if there aren't any matching rows.

### RegrSXX

**class** **RegrSXX** (*y, x*)

Returns  $\text{sum}(x^2) - \text{sum}(x)^2/N$  ("sum of squares" of the independent variable) as a `float`, or `None` if there aren't any matching rows.

### RegrSXY

**class** **RegrSXY** (*y, x*)

Returns  $\text{sum}(x*y) - \text{sum}(x) * \text{sum}(y)/N$  ("sum of products" of independent times dependent variable) as a `float`, or `None` if there aren't any matching rows.

### RegrSYY

**class** **RegrSYY** (*y, x*)

Returns  $\text{sum}(y^2) - \text{sum}(y)^2/N$  ("sum of squares" of the dependent variable) as a `float`, or `None` if there aren't any matching rows.

## Usage examples

We will use this example table:

FIELD1	FIELD2	FIELD3
foo	1	13
bar	2	(null)
test	3	13

Here's some examples of some of the general-purpose aggregation functions:

```
>>> TestModel.objects.aggregate(result=StringAgg('field1', delimiter=';'))
{'result': 'foo;bar;test'}
>>> TestModel.objects.aggregate(result=ArrayAgg('field2'))
{'result': [1, 2, 3]}
>>> TestModel.objects.aggregate(result=ArrayAgg('field1'))
{'result': ['foo', 'bar', 'test']}
```

The next example shows the usage of statistical aggregate functions. The underlying math will be not described (you can read about this, for example, at [wikipedia](#)):

```
>>> TestModel.objects.aggregate(count=RegrCount(y='field3', x='field2'))
{'count': 2}
>>> TestModel.objects.aggregate(avgx=RegrAvgX(y='field3', x='field2'),
...                               avgy=RegrAvgY(y='field3', x='field2'))
{'avgx': 2, 'avgy': 13}
```

## PostgreSQL specific model fields

All of these fields are available from the `django.contrib.postgres.fields` module.

### ArrayField

**class** `ArrayField` (*base\_field*, *size=None*, *\*\*options*)

A field for storing lists of data. Most field types can be used, you simply pass another field instance as the *base\_field*. You may also specify a *size*. `ArrayField` can be nested to store multi-dimensional arrays.

If you give the field a *default*, ensure it's a callable such as `list` (for an empty default) or a callable that returns a list (such as a function). Incorrectly using `default=[]` creates a mutable default that is shared between all instances of `ArrayField`.

#### **base\_field**

This is a required argument.

Specifies the underlying data type and behavior for the array. It should be an instance of a subclass of `Field`. For example, it could be an `IntegerField` or a `CharField`. Most field types are permitted, with the exception of those handling relational data (`ForeignKey`, `OneToOneField` and `ManyToManyField`).

It is possible to nest array fields - you can specify an instance of `ArrayField` as the *base\_field*. For example:

```
from django.db import models
from django.contrib.postgres.fields import ArrayField

class ChessBoard(models.Model):
    board = ArrayField(
        ArrayField(
```

```
        models.CharField(max_length=10, blank=True),
        size=8,
    ),
    size=8,
)
```

Transformation of values between the database and the model, validation of data and configuration, and serialization are all delegated to the underlying base field.

**size**

This is an optional argument.

If passed, the array will have a maximum size as specified. This will be passed to the database, although PostgreSQL at present does not enforce the restriction.

---

**Note:** When nesting `ArrayField`, whether you use the `size` parameter or not, PostgreSQL requires that the arrays are rectangular:

```
from django.contrib.postgres.fields import ArrayField
from django.db import models

class Board(models.Model):
    pieces = ArrayField(ArrayField(models.IntegerField()))

# Valid
Board(pieces=[
    [2, 3],
    [2, 1],
])

# Not valid
Board(pieces=[
    [2, 3],
    [2],
])
```

If irregular shapes are required, then the underlying field should be made nullable and the values padded with `None`.

---

## Querying `ArrayField`

There are a number of custom lookups and transforms for `ArrayField`. We will use the following example model:

```
from django.db import models
from django.contrib.postgres.fields import ArrayField

class Post(models.Model):
    name = models.CharField(max_length=200)
    tags = ArrayField(models.CharField(max_length=200), blank=True)

    def __str__(self): # __unicode__ on Python 2
        return self.name
```

## contains

The `contains` lookup is overridden on `ArrayField`. The returned objects will be those where the values passed are a subset of the data. It uses the SQL operator `@>`. For example:

```
>>> Post.objects.create(name='First post', tags=['thoughts', 'django'])
>>> Post.objects.create(name='Second post', tags=['thoughts'])
>>> Post.objects.create(name='Third post', tags=['tutorial', 'django'])

>>> Post.objects.filter(tags__contains=['thoughts'])
<QuerySet [ <Post: First post>, <Post: Second post> ]>

>>> Post.objects.filter(tags__contains=['django'])
<QuerySet [ <Post: First post>, <Post: Third post> ]>

>>> Post.objects.filter(tags__contains=['django', 'thoughts'])
<QuerySet [ <Post: First post> ]>
```

## contained\_by

This is the inverse of the `contains` lookup - the objects returned will be those where the data is a subset of the values passed. It uses the SQL operator `<@`. For example:

```
>>> Post.objects.create(name='First post', tags=['thoughts', 'django'])
>>> Post.objects.create(name='Second post', tags=['thoughts'])
>>> Post.objects.create(name='Third post', tags=['tutorial', 'django'])

>>> Post.objects.filter(tags__contained_by=['thoughts', 'django'])
<QuerySet [ <Post: First post>, <Post: Second post> ]>

>>> Post.objects.filter(tags__contained_by=['thoughts', 'django', 'tutorial'])
<QuerySet [ <Post: First post>, <Post: Second post>, <Post: Third post> ]>
```

## overlap

Returns objects where the data shares any results with the values passed. Uses the SQL operator `&&`. For example:

```
>>> Post.objects.create(name='First post', tags=['thoughts', 'django'])
>>> Post.objects.create(name='Second post', tags=['thoughts'])
>>> Post.objects.create(name='Third post', tags=['tutorial', 'django'])

>>> Post.objects.filter(tags__overlap=['thoughts'])
<QuerySet [ <Post: First post>, <Post: Second post> ]>

>>> Post.objects.filter(tags__overlap=['thoughts', 'tutorial'])
<QuerySet [ <Post: First post>, <Post: Second post>, <Post: Third post> ]>
```

## len

Returns the length of the array. The lookups available afterwards are those available for `IntegerField`. For example:

```
>>> Post.objects.create(name='First post', tags=['thoughts', 'django'])
>>> Post.objects.create(name='Second post', tags=['thoughts'])

>>> Post.objects.filter(tags__len=1)
<QuerySet [<Post: Second post>]>
```

## Index transforms

This class of transforms allows you to index into the array in queries. Any non-negative integer can be used. There are no errors if it exceeds the *size* of the array. The lookups available after the transform are those from the *base\_field*. For example:

```
>>> Post.objects.create(name='First post', tags=['thoughts', 'django'])
>>> Post.objects.create(name='Second post', tags=['thoughts'])

>>> Post.objects.filter(tags__0='thoughts')
<QuerySet [<Post: First post>, <Post: Second post>]>

>>> Post.objects.filter(tags__1__iexact='Django')
<QuerySet [<Post: First post>]>

>>> Post.objects.filter(tags__276='javascript')
<QuerySet []>
```

---

**Note:** PostgreSQL uses 1-based indexing for array fields when writing raw SQL. However these indexes and those used in *slices* use 0-based indexing to be consistent with Python.

---

## Slice transforms

This class of transforms allow you to take a slice of the array. Any two non-negative integers can be used, separated by a single underscore. The lookups available after the transform do not change. For example:

```
>>> Post.objects.create(name='First post', tags=['thoughts', 'django'])
>>> Post.objects.create(name='Second post', tags=['thoughts'])
>>> Post.objects.create(name='Third post', tags=['django', 'python', 'thoughts'])

>>> Post.objects.filter(tags__0_1=['thoughts'])
<QuerySet [<Post: First post>, <Post: Second post>]>

>>> Post.objects.filter(tags__0_2__contains=['thoughts'])
<QuerySet [<Post: First post>, <Post: Second post>]>
```

---

**Note:** PostgreSQL uses 1-based indexing for array fields when writing raw SQL. However these slices and those used in *indexes* use 0-based indexing to be consistent with Python.

---

## Multidimensional arrays with indexes and slices

PostgreSQL has some rather esoteric behavior when using indexes and slices on multidimensional arrays. It will always work to use indexes to reach down to the final underlying data, but most other slices behave strangely at the

database level and cannot be supported in a logical, consistent fashion by Django.

---

## Indexing ArrayField

At present using `db_index` will create a `btree` index. This does not offer particularly significant help to querying. A more useful index is a GIN index, which you should create using a `RunSQL` operation.

## HStoreField

**class** `HStoreField` (\*\*options)

A field for storing mappings of strings to strings. The Python data type used is a `dict`.

To use this field, you'll need to:

1. Add `'django.contrib.postgres'` in your `INSTALLED_APPS`.
2. *Setup the `hstore` extension* in PostgreSQL.

You'll see an error like `can't adapt type 'dict'` if you skip the first step, or type `"hstore"` does not exist if you skip the second.

---

**Note:** On occasions it may be useful to require or restrict the keys which are valid for a given field. This can be done using the `KeysValidator`.

---

## Querying HStoreField

In addition to the ability to query by key, there are a number of custom lookups available for `HStoreField`.

We will use the following example model:

```
from django.contrib.postgres.fields import HStoreField
from django.db import models

class Dog(models.Model):
    name = models.CharField(max_length=200)
    data = HStoreField()

    def __str__(self): # __unicode__ on Python 2
        return self.name
```

## Key lookups

To query based on a given key, you simply use that key as the lookup name:

```
>>> Dog.objects.create(name='Rufus', data={'breed': 'labrador'})
>>> Dog.objects.create(name='Meg', data={'breed': 'collie'})

>>> Dog.objects.filter(data__breed='collie')
<QuerySet [<Dog: Meg>]>
```

You can chain other lookups after key lookups:

```
>>> Dog.objects.filter(data__breed__contains='l')
<QuerySet [<Dog: Rufus>, <Dog: Meg>]>
```

If the key you wish to query by clashes with the name of another lookup, you need to use the *hstorefield.contains* lookup instead.

**Warning:** Since any string could be a key in a hstore value, any lookup other than those listed below will be interpreted as a key lookup. No errors are raised. Be extra careful for typing mistakes, and always check your queries work as you intend.

### contains

The *contains* lookup is overridden on *HStoreField*. The returned objects are those where the given dict of key-value pairs are all contained in the field. It uses the SQL operator @>. For example:

```
>>> Dog.objects.create(name='Rufus', data={'breed': 'labrador', 'owner': 'Bob'})
>>> Dog.objects.create(name='Meg', data={'breed': 'collie', 'owner': 'Bob'})
>>> Dog.objects.create(name='Fred', data={})

>>> Dog.objects.filter(data__contains={'owner': 'Bob'})
<QuerySet [<Dog: Rufus>, <Dog: Meg>]>

>>> Dog.objects.filter(data__contains={'breed': 'collie'})
<QuerySet [<Dog: Meg>]>
```

### contained\_by

This is the inverse of the *contains* lookup - the objects returned will be those where the key-value pairs on the object are a subset of those in the value passed. It uses the SQL operator <@. For example:

```
>>> Dog.objects.create(name='Rufus', data={'breed': 'labrador', 'owner': 'Bob'})
>>> Dog.objects.create(name='Meg', data={'breed': 'collie', 'owner': 'Bob'})
>>> Dog.objects.create(name='Fred', data={})

>>> Dog.objects.filter(data__contained_by={'breed': 'collie', 'owner': 'Bob'})
<QuerySet [<Dog: Meg>, <Dog: Fred>]>

>>> Dog.objects.filter(data__contained_by={'breed': 'collie'})
<QuerySet [<Dog: Fred>]>
```

### has\_key

Returns objects where the given key is in the data. Uses the SQL operator ?. For example:

```
>>> Dog.objects.create(name='Rufus', data={'breed': 'labrador'})
>>> Dog.objects.create(name='Meg', data={'breed': 'collie', 'owner': 'Bob'})

>>> Dog.objects.filter(data__has_key='owner')
<QuerySet [<Dog: Meg>]>
```

### has\_any\_keys

Returns objects where any of the given keys are in the data. Uses the SQL operator `?|`. For example:

```
>>> Dog.objects.create(name='Rufus', data={'breed': 'labrador'})
>>> Dog.objects.create(name='Meg', data={'owner': 'Bob'})
>>> Dog.objects.create(name='Fred', data={})

>>> Dog.objects.filter(data__has_any_keys=['owner', 'breed'])
<QuerySet [<Dog: Rufus>, <Dog: Meg>]>
```

### has\_keys

Returns objects where all of the given keys are in the data. Uses the SQL operator `?&`. For example:

```
>>> Dog.objects.create(name='Rufus', data={})
>>> Dog.objects.create(name='Meg', data={'breed': 'collie', 'owner': 'Bob'})

>>> Dog.objects.filter(data__has_keys=['breed', 'owner'])
<QuerySet [<Dog: Meg>]>
```

### keys

Returns objects where the array of keys is the given value. Note that the order is not guaranteed to be reliable, so this transform is mainly useful for using in conjunction with lookups on `ArrayField`. Uses the SQL function `akeys()`. For example:

```
>>> Dog.objects.create(name='Rufus', data={'toy': 'bone'})
>>> Dog.objects.create(name='Meg', data={'breed': 'collie', 'owner': 'Bob'})

>>> Dog.objects.filter(data__keys__overlap=['breed', 'toy'])
<QuerySet [<Dog: Rufus>, <Dog: Meg>]>
```

### values

Returns objects where the array of values is the given value. Note that the order is not guaranteed to be reliable, so this transform is mainly useful for using in conjunction with lookups on `ArrayField`. Uses the SQL function `avalues()`. For example:

```
>>> Dog.objects.create(name='Rufus', data={'breed': 'labrador'})
>>> Dog.objects.create(name='Meg', data={'breed': 'collie', 'owner': 'Bob'})

>>> Dog.objects.filter(data__values__contains=['collie'])
<QuerySet [<Dog: Meg>]>
```

## JSONField

### class `JSONField` (\*\*options)

A field for storing JSON encoded data. In Python the data is represented in its Python native format: dictionaries, lists, strings, numbers, booleans and None.

If you want to store other data types, you'll need to serialize them first. For example, you might cast a `datetime` to a string. You might also want to convert the string back to a `datetime` when you retrieve the data from the database. There are some third-party `JSONField` implementations which do this sort of thing automatically.

If you give the field a `default`, ensure it's a callable such as `dict` (for an empty default) or a callable that returns a `dict` (such as a function). Incorrectly using `default={}` creates a mutable default that is shared between all instances of `JSONField`.

---

**Note:** PostgreSQL has two native JSON based data types: `json` and `jsonb`. The main difference between them is how they are stored and how they can be queried. PostgreSQL's `json` field is stored as the original string representation of the JSON and must be decoded on the fly when queried based on keys. The `jsonb` field is stored based on the actual structure of the JSON which allows indexing. The trade-off is a small additional cost on writing to the `jsonb` field. `JSONField` uses `jsonb`.

**As a result, this field requires PostgreSQL  $\geq$  9.4 and Psycogp2  $\geq$  2.5.4.**

---

## Querying `JSONField`

We will use the following example model:

```
from django.contrib.postgres.fields import JSONField
from django.db import models

class Dog(models.Model):
    name = models.CharField(max_length=200)
    data = JSONField()

    def __str__(self): # __unicode__ on Python 2
        return self.name
```

## Key, index, and path lookups

To query based on a given dictionary key, simply use that key as the lookup name:

```
>>> Dog.objects.create(name='Rufus', data={
...     'breed': 'labrador',
...     'owner': {
...         'name': 'Bob',
...         'other_pets': [{
...             'name': 'Fishy',
...         }],
...     },
... })
>>> Dog.objects.create(name='Meg', data={'breed': 'collie'})

>>> Dog.objects.filter(data__breed='collie')
<QuerySet [<Dog: Meg>]>
```

Multiple keys can be chained together to form a path lookup:

```
>>> Dog.objects.filter(data__owner__name='Bob')
<QuerySet [<Dog: Rufus>]>
```

If the key is an integer, it will be interpreted as an index lookup in an array:

```
>>> Dog.objects.filter(data__owner__other_pets__0__name='Fishy')
<QuerySet [ <Dog: Rufus> ]>
```

If the key you wish to query by clashes with the name of another lookup, use the `jsonfield.contains` lookup instead.

If only one key or index is used, the SQL operator `->` is used. If multiple operators are used then the `#>` operator is used.

**Warning:** Since any string could be a key in a JSON object, any lookup other than those listed below will be interpreted as a key lookup. No errors are raised. Be extra careful for typing mistakes, and always check your queries work as you intend.

## Containment and key operations

`JSONField` shares lookups relating to containment and keys with `HStoreField`.

- `contains` (accepts any JSON rather than just a dictionary of strings)
- `contained_by` (accepts any JSON rather than just a dictionary of strings)
- `has_key`
- `has_any_keys`
- `has_keys`

## Range Fields

There are five range field types, corresponding to the built-in range types in PostgreSQL. These fields are used to store a range of values; for example the start and end timestamps of an event, or the range of ages an activity is suitable for.

All of the range fields translate to `psycopg2 Range` objects in python, but also accept tuples as input if no bounds information is necessary. The default is lower bound included, upper bound excluded; that is, `[ )`.

### IntegerRangeField

**class IntegerRangeField** (*\*\*options*)

Stores a range of integers. Based on an `IntegerField`. Represented by an `int4range` in the database and a `NumericRange` in Python.

Regardless of the bounds specified when saving the data, PostgreSQL always returns a range in a canonical form that includes the lower bound and excludes the upper bound; that is `[ )`.

### BigIntegerRangeField

**class BigIntegerRangeField** (*\*\*options*)

Stores a range of large integers. Based on a `BigIntegerField`. Represented by an `int8range` in the database and a `NumericRange` in Python.

Regardless of the bounds specified when saving the data, PostgreSQL always returns a range in a canonical form that includes the lower bound and excludes the upper bound; that is `[ )`.

### FloatRangeField

**class** `FloatRangeField` (\*\*options)

Stores a range of floating point values. Based on a `FloatField`. Represented by a `numrange` in the database and a `NumericRange` in Python.

### DateTimeRangeField

**class** `DateTimeRangeField` (\*\*options)

Stores a range of timestamps. Based on a `DateTimeField`. Represented by a `tztsrange` in the database and a `DateTimeTZRange` in Python.

### DateRangeField

**class** `DateRangeField` (\*\*options)

Stores a range of dates. Based on a `DateField`. Represented by a `daterange` in the database and a `DateRange` in Python.

Regardless of the bounds specified when saving the data, PostgreSQL always returns a range in a canonical form that includes the lower bound and excludes the upper bound; that is `[]`.

## Querying Range Fields

There are a number of custom lookups and transforms for range fields. They are available on all the above fields, but we will use the following example model:

```
from django.contrib.postgres.fields import IntegerRangeField
from django.db import models

class Event(models.Model):
    name = models.CharField(max_length=200)
    ages = IntegerRangeField()
    start = models.DateTimeField()

    def __str__(self): # __unicode__ on Python 2
        return self.name
```

We will also use the following example objects:

```
>>> import datetime
>>> from django.utils import timezone
>>> now = timezone.now()
>>> Event.objects.create(name='Soft play', ages=(0, 10), start=now)
>>> Event.objects.create(name='Pub trip', ages=(21, None), start=now -
↳datetime.timedelta(days=1))
```

and `NumericRange`:

```
>>> from psycopg2.extras import NumericRange
```

## Containment functions

As with other PostgreSQL fields, there are three standard containment operators: `contains`, `contained_by` and `overlap`, using the SQL operators `@>`, `<@`, and `&&` respectively.

### `contains`

```
>>> Event.objects.filter(ages__contains=NumericRange(4, 5))
<QuerySet [<Event: Soft play>]>
```

### `contained_by`

```
>>> Event.objects.filter(ages__contained_by=NumericRange(0, 15))
<QuerySet [<Event: Soft play>]>
```

The `contained_by` lookup is also available on the non-range field types: `IntegerField`, `BigIntegerField`, `FloatField`, `DateField`, and `DateTimeField`. For example:

```
>>> from psycopg2.extras import DateTimeTZRange
>>> Event.objects.filter(start__contained_by=DateTimeTZRange(
...     timezone.now() - datetime.timedelta(hours=1),
...     timezone.now() + datetime.timedelta(hours=1),
... ))
<QuerySet [<Event: Soft play>]>
```

### `overlap`

```
>>> Event.objects.filter(ages__overlap=NumericRange(8, 12))
<QuerySet [<Event: Soft play>]>
```

## Comparison functions

Range fields support the standard lookups: `lt`, `gt`, `lte` and `gte`. These are not particularly helpful - they compare the lower bounds first and then the upper bounds only if necessary. This is also the strategy used to order by a range field. It is better to use the specific range comparison operators.

### `fully_lt`

The returned ranges are strictly less than the passed range. In other words, all the points in the returned range are less than all those in the passed range.

```
>>> Event.objects.filter(ages__fully_lt=NumericRange(11, 15))
<QuerySet [<Event: Soft play>]>
```

### fully\_gt

The returned ranges are strictly greater than the passed range. In other words, the all the points in the returned range are greater than all those in the passed range.

```
>>> Event.objects.filter(ages__fully_gt=NumericRange(11, 15))
<QuerySet [<Event: Pub trip>]>
```

### not\_lt

The returned ranges do not contain any points less than the passed range, that is the lower bound of the returned range is at least the lower bound of the passed range.

```
>>> Event.objects.filter(ages__not_lt=NumericRange(0, 15))
<QuerySet [<Event: Soft play>, <Event: Pub trip>]>
```

### not\_gt

The returned ranges do not contain any points greater than the passed range, that is the upper bound of the returned range is at most the upper bound of the passed range.

```
>>> Event.objects.filter(ages__not_gt=NumericRange(3, 10))
<QuerySet [<Event: Soft play>]>
```

### adjacent\_to

The returned ranges share a bound with the passed range.

```
>>> Event.objects.filter(ages__adjacent_to=NumericRange(10, 21))
<QuerySet [<Event: Soft play>, <Event: Pub trip>]>
```

## Querying using the bounds

There are three transforms available for use in queries. You can extract the lower or upper bound, or query based on emptiness.

### startswith

Returned objects have the given lower bound. Can be chained to valid lookups for the base field.

```
>>> Event.objects.filter(ages__startswith=21)
<QuerySet [<Event: Pub trip>]>
```

### endswith

Returned objects have the given upper bound. Can be chained to valid lookups for the base field.

```
>>> Event.objects.filter(ages__endswith=10)
<QuerySet [<Event: Soft play>]>
```

### **isempty**

Returned objects are empty ranges. Can be chained to valid lookups for a *BooleanField*.

```
>>> Event.objects.filter(ages__isempty=True)
<QuerySet []>
```

## Defining your own range types

PostgreSQL allows the definition of custom range types. Django's model and form field implementations use base classes below, and `psycpg2` provides a `register_range()` to allow use of custom range types.

```
class RangeField (**options)
```

Base class for model range fields.

**base\_field**

The model field class to use.

**range\_type**

The `psycpg2` range type to use.

**form\_field**

The form field class to use. Should be a subclass of `django.contrib.postgres.forms.BaseRangeField`.

```
class django.contrib.postgres.forms.BaseRangeField
```

Base class for form range fields.

**base\_field**

The form field to use.

**range\_type**

The `psycpg2` range type to use.

## PostgreSQL specific form fields and widgets

All of these fields and widgets are available from the `django.contrib.postgres.forms` module.

### Fields

#### **SimpleArrayField**

```
class SimpleArrayField (base_field, delimiter=',', max_length=None, min_length=None)
```

A simple field which maps to an array. It is represented by an HTML `<input>`.

**base\_field**

This is a required argument.

It specifies the underlying form field for the array. This is not used to render any HTML, but it is used to process the submitted data and validate it. For example:

```
>>> from django.contrib.postgres.forms import SimpleArrayField
>>> from django import forms

>>> class NumberListForm(forms.Form):
...     numbers = SimpleArrayField(forms.IntegerField())

>>> form = NumberListForm({'numbers': '1,2,3'})
>>> form.is_valid()
True
>>> form.cleaned_data
{'numbers': [1, 2, 3]}

>>> form = NumberListForm({'numbers': '1,2,a'})
>>> form.is_valid()
False
```

### delimiter

This is an optional argument which defaults to a comma: `,`. This value is used to split the submitted data. It allows you to chain `SimpleArrayField` for multidimensional data:

```
>>> from django.contrib.postgres.forms import SimpleArrayField
>>> from django import forms

>>> class GridForm(forms.Form):
...     places = SimpleArrayField(SimpleArrayField(IntegerField()), delimiter=
↳ '|')

>>> form = GridForm({'places': '1,2|2,1|4,3'})
>>> form.is_valid()
True
>>> form.cleaned_data
{'places': [[1, 2], [2, 1], [4, 3]]}
```

---

**Note:** The field does not support escaping of the delimiter, so be careful in cases where the delimiter is a valid character in the underlying field. The delimiter does not need to be only one character.

---

### max\_length

This is an optional argument which validates that the array does not exceed the stated length.

### min\_length

This is an optional argument which validates that the array reaches at least the stated length.

---

### User friendly forms

`SimpleArrayField` is not particularly user friendly in most cases, however it is a useful way to format data from a client-side widget for submission to the server.

---

## SplitArrayField

**class** `SplitArrayField` (*base\_field*, *size*, *remove\_trailing\_nulls=False*)

This field handles arrays by reproducing the underlying field a fixed number of times.

**base\_field**

This is a required argument. It specifies the form field to be repeated.

**size**

This is the fixed number of times the underlying field will be used.

**remove\_trailing\_nulls**

By default, this is set to `False`. When `False`, each value from the repeated fields is stored. When set to `True`, any trailing values which are blank will be stripped from the result. If the underlying field has `required=True`, but `remove_trailing_nulls` is `True`, then null values are only allowed at the end, and will be stripped.

Some examples:

```
SplitArrayField(IntegerField(required=True), size=3, remove_trailing_
↳nulls=False)

['1', '2', '3'] # -> [1, 2, 3]
['1', '2', ''] # -> ValidationError - third entry required.
['1', '', '3'] # -> ValidationError - second entry required.
['', '2', ''] # -> ValidationError - first and third entries required.

SplitArrayField(IntegerField(required=False), size=3, remove_trailing_
↳nulls=False)

['1', '2', '3'] # -> [1, 2, 3]
['1', '2', ''] # -> [1, 2, None]
['1', '', '3'] # -> [1, None, 3]
['', '2', ''] # -> [None, 2, None]

SplitArrayField(IntegerField(required=True), size=3, remove_trailing_
↳nulls=True)

['1', '2', '3'] # -> [1, 2, 3]
['1', '2', ''] # -> [1, 2]
['1', '', '3'] # -> ValidationError - second entry required.
['', '2', ''] # -> ValidationError - first entry required.

SplitArrayField(IntegerField(required=False), size=3, remove_trailing_
↳nulls=True)

['1', '2', '3'] # -> [1, 2, 3]
['1', '2', ''] # -> [1, 2]
['1', '', '3'] # -> [1, None, 3]
['', '2', ''] # -> [None, 2]
```

**HStoreField****class HStoreField**

A field which accepts JSON encoded data for an `HStoreField`. It will cast all the values to strings. It is represented by an HTML `<textarea>`.

**User friendly forms**

`HStoreField` is not particularly user friendly in most cases, however it is a useful way to format data from a client-side widget for submission to the server.

---

**Note:** On occasions it may be useful to require or restrict the keys which are valid for a given field. This can be done using the *KeysValidator*.

---

## JSONField

### class JSONField

A field which accepts JSON encoded data for a *JSONField*. It is represented by an HTML `<textarea>`.

---

### User friendly forms

*JSONField* is not particularly user friendly in most cases, however it is a useful way to format data from a client-side widget for submission to the server.

---

## Range Fields

This group of fields all share similar functionality for accepting range data. They are based on *MultiValueField*. They treat one omitted value as an unbounded range. They also validate that the lower bound is not greater than the upper bound. All of these fields use *RangeWidget*.

### IntegerRangeField

#### class IntegerRangeField

Based on *IntegerField* and translates its input into *NumericRange*. Default for *IntegerRangeField* and *BigIntegerRangeField*.

### FloatRangeField

#### class FloatRangeField

Based on *FloatField* and translates its input into *NumericRange*. Default for *FloatRangeField*.

### DateTimeRangeField

#### class DateTimeRangeField

Based on *DateTimeField* and translates its input into *DateTimeTZRange*. Default for *DateTimeRangeField*.

### DateRangeField

#### class DateRangeField

Based on *DateField* and translates its input into *DateRange*. Default for *DateRangeField*.

## Widgets

### RangeWidget

**class RangeWidget** (*base\_widget*, *attrs=None*)

Widget used by all of the range fields. Based on *MultiWidget*.

*RangeWidget* has one required argument:

**base\_widget**

A *RangeWidget* comprises a 2-tuple of *base\_widget*.

**decompress** (*value*)

Takes a single “compressed” value of a field, for example a *DateRangeField*, and returns a tuple representing and lower and upper bound.

## PostgreSQL specific database functions

All of these functions are available from the `django.contrib.postgres.functions` module.

### TransactionNow

**class TransactionNow**

Returns the date and time on the database server that the current transaction started. If you are not in a transaction it will return the date and time of the current statement. This is a complement to `django.db.models.functions.Now`, which returns the date and time of the current statement.

Note that only the outermost call to `atomic()` sets up a transaction and thus sets the time that `TransactionNow()` will return; nested calls create savepoints which do not affect the transaction time.

Usage example:

```
>>> from django.contrib.postgres.functions import TransactionNow
>>> Article.objects.filter(published__lte=TransactionNow())
<QuerySet [ <Article: How to Django > ]>
```

## PostgreSQL specific lookups

### Trigram similarity

The `trigram_similar` lookup allows you to perform trigram lookups, measuring the number of trigrams (three consecutive characters) shared, using a dedicated PostgreSQL extension. A trigram lookup is given an expression and returns results that have a similarity measurement greater than the current similarity threshold.

To use it, add `'django.contrib.postgres'` in your `INSTALLED_APPS` and activate the `pg_trgm` extension on PostgreSQL. You can install the extension using the `TrigramExtension` migration operation.

The `trigram_similar` lookup can be used on `CharField` and `TextField`:

```
>>> City.objects.filter(name__trigram_similar="Middlesborough")
[ <City: Middlesbrough > ]
```

## Unaccent

The `unaccent` lookup allows you to perform accent-insensitive lookups using a dedicated PostgreSQL extension.

This lookup is implemented using *Transform*, so it can be chained with other lookup functions. To use it, you need to add `'django.contrib.postgres'` in your `INSTALLED_APPS` and activate the `unaccent` extension on PostgreSQL. The `UnaccentExtension` migration operation is available if you want to perform this activation using migrations).

The `unaccent` lookup can be used on `CharField` and `TextField`:

```
>>> City.objects.filter(name__unaccent="México")
['<City: Mexico>']

>>> User.objects.filter(first_name__unaccent__startswith="Jerem")
['<User: Jeremy>', '<User: Jérémy>', '<User: Jérémie>', '<User: Jeremie>']
```

**Warning:** `unaccent` lookups should perform fine in most use cases. However, queries using this filter will generally perform full table scans, which can be slow on large tables. In those cases, using dedicated full text indexing tools might be appropriate.

## Database migration operations

All of these *operations* are available from the `django.contrib.postgres.operations` module.

### Creating extension using migrations

You can create a PostgreSQL extension in your database using a migration file. This example creates an `hstore` extension, but the same principles apply for other extensions.

Set up the `hstore` extension in PostgreSQL before the first `CreateModel` or `AddField` operation that involves `HStoreField` by adding a migration with the `HStoreExtension` operation. For example:

```
from django.contrib.postgres.operations import HStoreExtension

class Migration(migrations.Migration):
    ...

    operations = [
        HStoreExtension(),
        ...
    ]
```

Creating the extension requires a database user with superuser privileges. If the Django database user doesn't have superuser privileges, you'll have to create the extension outside of Django migrations with a user that has the appropriate privileges. In that case, connect to your Django database and run the query `CREATE EXTENSION IF NOT EXISTS hstore;`.

### CreateExtension

**class** `CreateExtension` (*name*)

An `Operation` subclass which installs PostgreSQL extensions.

**name**

This is a required argument. The name of the extension to be installed.

**HStoreExtension****class HStoreExtension**

Installs the `hstore` extension and also sets up the connection to interpret hstore data for possible use in subsequent migrations.

**TrigramExtension****class TrigramExtension**

Installs the `pg_trgm` extension.

**UnaccentExtension****class UnaccentExtension**

Installs the `unaccent` extension.

**Full text search**

The database functions in the `django.contrib.postgres.search` module ease the use of PostgreSQL's full text search engine.

For the examples in this document, we'll use the models defined in *Making queries*.

**See also:**

For a high-level overview of searching, see the *topic documentation*.

**The search lookup**

The simplest way to use full text search is to search a single term against a single column in the database. For example:

```
>>> Entry.objects.filter(body_text__search='Cheese')
[<Entry: Cheese on Toast recipes>, <Entry: Pizza Recipes>]
```

This creates a `to_tsvector` in the database from the `body_text` field and a `plainto_tsquery` from the search term 'Cheese', both using the default database search configuration. The results are obtained by matching the query and the vector.

To use the search lookup, 'django.contrib.postgres' must be in your `INSTALLED_APPS`.

**SearchVector****class SearchVector** (\*expressions, config=None, weight=None)

Searching against a single field is great but rather limiting. The `Entry` instances we're searching belong to a `Blog`, which has a `tagline` field. To query against both fields, use a `SearchVector`:

```
>>> from django.contrib.postgres.search import SearchVector
>>> Entry.objects.annotate(
...     search=SearchVector('body_text', 'blog_tagline'),
... ).filter(search='Cheese')
[<Entry: Cheese on Toast recipes>, <Entry: Pizza Recipes>]
```

The arguments to `SearchVector` can be any *Expression* or the name of a field. Multiple arguments will be concatenated together using a space so that the search document includes them all.

`SearchVector` objects can be combined together, allowing you to reuse them. For example:

```
>>> Entry.objects.annotate(
...     search=SearchVector('body_text') + SearchVector('blog_tagline'),
... ).filter(search='Cheese')
[<Entry: Cheese on Toast recipes>, <Entry: Pizza Recipes>]
```

See [Changing the search configuration](#) and [Weighting queries](#) for an explanation of the `config` and `weight` parameters.

## SearchQuery

**class SearchQuery** (*value, config=None*)

`SearchQuery` translates the terms the user provides into a search query object that the database compares to a search vector. By default, all the words the user provides are passed through the stemming algorithms, and then it looks for matches for all of the resulting terms.

`SearchQuery` terms can be combined logically to provide more flexibility:

```
>>> from django.contrib.postgres.search import SearchQuery
>>> SearchQuery('potato') & SearchQuery('ireland') # potato AND ireland
>>> SearchQuery('potato') | SearchQuery('penguin') # potato OR penguin
>>> ~SearchQuery('sausage') # NOT sausage
```

See [Changing the search configuration](#) for an explanation of the `config` parameter.

## SearchRank

**class SearchRank** (*vector, query, weights=None*)

So far, we've just returned the results for which any match between the vector and the query are possible. It's likely you may wish to order the results by some sort of relevancy. PostgreSQL provides a ranking function which takes into account how often the query terms appear in the document, how close together the terms are in the document, and how important the part of the document is where they occur. The better the match, the higher the value of the rank. To order by relevancy:

```
>>> from django.contrib.postgres.search import SearchQuery, SearchRank, SearchVector
>>> vector = SearchVector('body_text')
>>> query = SearchQuery('cheese')
>>> Entry.objects.annotate(rank=SearchRank(vector, query)).order_by('-rank')
[<Entry: Cheese on Toast recipes>, <Entry: Pizza recipes>]
```

See [Weighting queries](#) for an explanation of the `weights` parameter.

## Changing the search configuration

You can specify the `config` attribute to a `SearchVector` and `SearchQuery` to use a different search configuration. This allows using a different language parsers and dictionaries as defined by the database:

```
>>> from django.contrib.postgres.search import SearchQuery, SearchVector
>>> Entry.objects.annotate(
...     search=SearchVector('body_text', config='french'),
... ).filter(search=SearchQuery('œuf', config='french'))
[<Entry: Pain perdu>]
```

The value of `config` could also be stored in another column:

```
>>> from django.db.models import F
>>> Entry.objects.annotate(
...     search=SearchVector('body_text', config=F('blog__language')),
... ).filter(search=SearchQuery('œuf', config=F('blog__language')))
[<Entry: Pain perdu>]
```

## Weighting queries

Every field may not have the same relevance in a query, so you can set weights of various vectors before you combine them:

```
>>> from django.contrib.postgres.search import SearchQuery, SearchRank, SearchVector
>>> vector = SearchVector('body_text', weight='A') + SearchVector('blog__tagline',
↳ weight='B')
>>> query = SearchQuery('cheese')
>>> Entry.objects.annotate(rank=SearchRank(vector, query)).filter(rank__gte=0.3).
↳ order_by('rank')
```

The weight should be one of the following letters: D, C, B, A. By default, these weights refer to the numbers 0.1, 0.2, 0.4, and 1.0, respectively. If you wish to weight them differently, pass a list of four floats to `SearchRank` as weights in the same order above:

```
>>> rank = SearchRank(vector, query, weights=[0.2, 0.4, 0.6, 0.8])
>>> Entry.objects.annotate(rank=rank).filter(rank__gte=0.3).order_by('-rank')
```

## Performance

Special database configuration isn't necessary to use any of these functions, however, if you're searching more than a few hundred records, you're likely to run into performance problems. Full text search is a more intensive process than comparing the size of an integer, for example.

In the event that all the fields you're querying on are contained within one particular model, you can create a functional index which matches the search vector you wish to use. The PostgreSQL documentation has details on [creating indexes for full text search](#).

### SearchVectorField

```
class SearchVectorField
```

If this approach becomes too slow, you can add a `SearchVectorField` to your model. You'll need to keep it populated with triggers, for example, as described in the [PostgreSQL documentation](#). You can then query the field as if it were an annotated `SearchVector`:

```
>>> Entry.objects.update(search_vector=SearchVector('body_text'))
>>> Entry.objects.filter(search_vector='cheese')
[<Entry: Cheese on Toast recipes>, <Entry: Pizza recipes>]
```

## Trigram similarity

Another approach to searching is trigram similarity. A trigram is a group of three consecutive characters. In addition to the `trigram_similar` lookup, you can use a couple of other expressions.

To use them, you need to activate the `pg_trgm` extension on PostgreSQL. You can install it using the `TrigramExtension` migration operation.

### TrigramSimilarity

**class TrigramSimilarity** (*expression, string, \*\*extra*)

Accepts a field name or expression, and a string or expression. Returns the trigram similarity between the two arguments.

Usage example:

```
>>> from django.contrib.postgres.search import TrigramSimilarity
>>> Author.objects.create(name='Katy Stevens')
>>> Author.objects.create(name='Stephen Keats')
>>> test = 'Katie Stephens'
>>> Author.objects.annotate(
...     similarity=TrigramSimilarity('name', test),
... ).filter(similarity__gt=0.3).order_by('-similarity')
[<Author: Katy Stevens>, <Author: Stephen Keats>]
```

### TrigramDistance

**class TrigramDistance** (*expression, string, \*\*extra*)

Accepts a field name or expression, and a string or expression. Returns the trigram distance between the two arguments.

Usage example:

```
>>> from django.contrib.postgres.search import TrigramDistance
>>> Author.objects.create(name='Katy Stevens')
>>> Author.objects.create(name='Stephen Keats')
>>> test = 'Katie Stephens'
>>> Author.objects.annotate(
...     distance=TrigramDistance('name', test),
... ).filter(distance__lte=0.7).order_by('distance')
[<Author: Katy Stevens>, <Author: Stephen Keats>]
```

## Validators

### KeysValidator

**class KeysValidator** (*keys, strict=False, messages=None*)

Validates that the given keys are contained in the value. If `strict` is `True`, then it also checks that there are no other keys present.

The messages passed should be a dict containing the keys `missing_keys` and/or `extra_keys`.

---

**Note:** Note that this checks only for the existence of a given key, not that the value of a key is non-empty.

---

## Range validators

### RangeMaxValueValidator

**class RangeMaxValueValidator** (*limit\_value, message=None*)

Validates that the upper bound of the range is not greater than `limit_value`.

### RangeMinValueValidator

**class RangeMinValueValidator** (*limit\_value, message=None*)

Validates that the lower bound of the range is not less than the `limit_value`.

## 6.5.9 The redirects app

Django comes with an optional redirects application. It lets you store simple redirects in a database and handles the redirecting for you. It uses the HTTP response status code 301 `Moved Permanently` by default.

### Installation

To install the redirects app, follow these steps:

1. Ensure that the `django.contrib.sites` framework *is installed*.
2. Add `'django.contrib.redirects'` to your `INSTALLED_APPS` setting.
3. Add `'django.contrib.redirects.middleware.RedirectFallbackMiddleware'` to your `MIDDLEWARE` setting.
4. Run the command `manage.py migrate`.

### How it works

`manage.py migrate` creates a `django_redirect` table in your database. This is a simple lookup table with `site_id`, `old_path` and `new_path` fields.

The `RedirectFallbackMiddleware` does all of the work. Each time any Django application raises a 404 error, this middleware checks the redirects database for the requested URL as a last resort. Specifically, it checks for a redirect with the given `old_path` with a site ID that corresponds to the `SITE_ID` setting.

- If it finds a match, and `new_path` is not empty, it redirects to `new_path` using a 301 (“Moved Permanently”) redirect. You can subclass `RedirectFallbackMiddleware` and set `response_redirect_class` to `django.http.HttpResponseRedirect` to use a 302 Moved Temporarily redirect instead.
- If it finds a match, and `new_path` is empty, it sends a 410 (“Gone”) HTTP header and empty (content-less) response.
- If it doesn’t find a match, the request continues to be processed as usual.

The middleware only gets activated for 404s – not for 500s or responses of any other status code.

Note that the order of `MIDDLEWARE` matters. Generally, you can put `RedirectFallbackMiddleware` at the end of the list, because it’s a last resort.

For more on middleware, read the [middleware docs](#).

## How to add, change and delete redirects

### Via the admin interface

If you’ve activated the automatic Django admin interface, you should see a “Redirects” section on the admin index page. Edit redirects as you edit any other object in the system.

### Via the Python API

#### `class models.Redirect`

Redirects are represented by a standard *Django model*, which lives in `django/contrib/redirects/models.py`. You can access redirect objects via the *Django database API*.

## Middleware

#### `class middleware.RedirectFallbackMiddleware`

You can change the `HttpResponse` classes used by the middleware by creating a subclass of `RedirectFallbackMiddleware` and overriding `response_gone_class` and/or `response_redirect_class`.

##### `response_gone_class`

The `HttpResponse` class used when a `Redirect` is not found for the requested path or has a blank `new_path` value.

Defaults to `HttpResponseGone`.

##### `response_redirect_class`

The `HttpResponse` class that handles the redirect.

Defaults to `HttpResponsePermanentRedirect`.

## 6.5.10 The sitemap framework

Django comes with a high-level sitemap-generating framework that makes creating `sitemap` XML files easy.

## Overview

A sitemap is an XML file on your website that tells search-engine indexers how frequently your pages change and how “important” certain pages are in relation to other pages on your site. This information helps search engines index your site.

The Django sitemap framework automates the creation of this XML file by letting you express this information in Python code.

It works much like Django’s *syndication framework*. To create a sitemap, just write a *Sitemap* class and point to it in your *URLconf*.

## Installation

To install the sitemap app, follow these steps:

1. Add 'django.contrib.sitemaps' to your *INSTALLED\_APPS* setting.
2. Make sure your *TEMPLATES* setting contains a DjangoTemplates backend whose *APP\_DIRS* options is set to True. It’s in there by default, so you’ll only need to change this if you’ve changed that setting.
3. Make sure you’ve installed the *sites framework*.

(Note: The sitemap application doesn’t install any database tables. The only reason it needs to go into *INSTALLED\_APPS* is so that the *Loader()* template loader can find the default templates.)

## Initialization

```
views.sitemap(request, sitemaps, section=None, template_name='sitemap.xml', content_type='application/xml')
```

To activate sitemap generation on your Django site, add this line to your *URLconf*:

```
from django.contrib.sitemaps.views import sitemap

url(r'^sitemap\.xml$', sitemap, {'sitemaps': sitemaps},
    name='django.contrib.sitemaps.views.sitemap')
```

This tells Django to build a sitemap when a client accesses */sitemap.xml*.

The name of the sitemap file is not important, but the location is. Search engines will only index links in your sitemap for the current URL level and below. For instance, if *sitemap.xml* lives in your root directory, it may reference any URL in your site. However, if your sitemap lives at */content/sitemap.xml*, it may only reference URLs that begin with */content/*.

The sitemap view takes an extra, required argument: *{'sitemaps': sitemaps}*. *sitemaps* should be a dictionary that maps a short section label (e.g., *blog* or *news*) to its *Sitemap* class (e.g., *BlogSitemap* or *NewsSitemap*). It may also map to an *instance* of a *Sitemap* class (e.g., *BlogSitemap(some\_var)*).

## Sitemap classes

A *Sitemap* class is a simple Python class that represents a “section” of entries in your sitemap. For example, one *Sitemap* class could represent all the entries of your Weblog, while another could represent all of the events in your events calendar.

In the simplest case, all these sections get lumped together into one *sitemap.xml*, but it’s also possible to use the framework to generate a sitemap index that references individual sitemap files, one per section. (See *Creating a sitemap index* below.)

*Sitemap* classes must subclass `django.contrib.sitemaps.Sitemap`. They can live anywhere in your code-base.

## A simple example

Let's assume you have a blog system, with an `Entry` model, and you want your sitemap to include all the links to your individual blog entries. Here's how your sitemap class might look:

```
from django.contrib.sitemaps import Sitemap
from blog.models import Entry

class BlogSitemap(Sitemap):
    changefreq = "never"
    priority = 0.5

    def items(self):
        return Entry.objects.filter(is_draft=False)

    def lastmod(self, obj):
        return obj.pub_date
```

Note:

- *changefreq* and *priority* are class attributes corresponding to `<changefreq>` and `<priority>` elements, respectively. They can be made callable as functions, as *lastmod* was in the example.
- *items()* is simply a method that returns a list of objects. The objects returned will get passed to any callable methods corresponding to a sitemap property (*location*, *lastmod*, *changefreq*, and *priority*).
- *lastmod* should return a `datetime`.
- There is no *location* method in this example, but you can provide it in order to specify the URL for your object. By default, *location()* calls `get_absolute_url()` on each object and returns the result.

## Sitemap class reference

### class Sitemap

A `Sitemap` class can define the following methods/attributes:

#### **items**

**Required.** A method that returns a list of objects. The framework doesn't care what *type* of objects they are; all that matters is that these objects get passed to the *location()*, *lastmod()*, *changefreq()* and *priority()* methods.

#### **location**

**Optional.** Either a method or attribute.

If it's a method, it should return the absolute path for a given object as returned by *items()*.

If it's an attribute, its value should be a string representing an absolute path to use for *every* object returned by *items()*.

In both cases, "absolute path" means a URL that doesn't include the protocol or domain. Examples:

- Good:  `'/foo/bar/'`
- Bad:  `'example.com/foo/bar/'`
- Bad:  `'https://example.com/foo/bar/'`

If *location* isn't provided, the framework will call the `get_absolute_url()` method on each object as returned by `items()`.

To specify a protocol other than 'http', use *protocol*.

#### **lastmod**

**Optional.** Either a method or attribute.

If it's a method, it should take one argument – an object as returned by `items()` – and return that object's last-modified date/time as a `datetime`.

If it's an attribute, its value should be a `datetime` representing the last-modified date/time for *every* object returned by `items()`.

If all items in a sitemap have a *lastmod*, the sitemap generated by `views.sitemap()` will have a Last-Modified header equal to the latest *lastmod*. You can activate the `ConditionalGetMiddleware` to make Django respond appropriately to requests with an If-Modified-Since header which will prevent sending the sitemap if it hasn't changed.

#### **changefreq**

**Optional.** Either a method or attribute.

If it's a method, it should take one argument – an object as returned by `items()` – and return that object's change frequency as a string.

If it's an attribute, its value should be a string representing the change frequency of *every* object returned by `items()`.

Possible values for *changefreq*, whether you use a method or attribute, are:

- 'always'
- 'hourly'
- 'daily'
- 'weekly'
- 'monthly'
- 'yearly'
- 'never'

#### **priority**

**Optional.** Either a method or attribute.

If it's a method, it should take one argument – an object as returned by `items()` – and return that object's priority as either a string or float.

If it's an attribute, its value should be either a string or float representing the priority of *every* object returned by `items()`.

Example values for *priority*: 0.4, 1.0. The default priority of a page is 0.5. See the [sitemaps.org documentation](#) for more.

#### **protocol**

**Optional.**

This attribute defines the protocol ('http' or 'https') of the URLs in the sitemap. If it isn't set, the protocol with which the sitemap was requested is used. If the sitemap is built outside the context of a request, the default is 'http'.

#### **limit**

**Optional.**

This attribute defines the maximum number of URLs included on each page of the sitemap. Its value should not exceed the default value of 50000, which is the upper limit allowed in the [Sitemaps protocol](#).

#### **i18n** **Optional.**

A boolean attribute that defines if the URLs of this sitemap should be generated using all of your [LANGUAGES](#). The default is `False`.

## Shortcuts

The sitemap framework provides a convenience class for a common case:

### **class GenericSitemap**

The `django.contrib.sitemaps.GenericSitemap` class allows you to create a sitemap by passing it a dictionary which has to contain at least a `queryset` entry. This queryset will be used to generate the items of the sitemap. It may also have a `date_field` entry that specifies a date field for objects retrieved from the queryset. This will be used for the `lastmod` attribute in the generated sitemap. You may also pass `priority` and `changefreq` keyword arguments to the `GenericSitemap` constructor to specify these attributes for all URLs.

## Example

Here's an example of a [URLconf](#) using `GenericSitemap`:

```
from django.conf.urls import url
from django.contrib.sitemaps import GenericSitemap
from django.contrib.sitemaps.views import sitemap
from blog.models import Entry

info_dict = {
    'queryset': Entry.objects.all(),
    'date_field': 'pub_date',
}

urlpatterns = [
    # some generic view using info_dict
    # ...

    # the sitemap
    url(r'^sitemap\.xml$', sitemap,
        {'sitemaps': {'blog': GenericSitemap(info_dict, priority=0.6)}},
        name='django.contrib.sitemaps.views.sitemap'),
]
```

## Sitemap for static views

Often you want the search engine crawlers to index views which are neither object detail pages nor flatpages. The solution is to explicitly list URL names for these views in `items` and call `reverse()` in the `location` method of the sitemap. For example:

```
# sitemaps.py
from django.contrib import sitemaps
from django.urls import reverse
```

```

class StaticViewSitemap(sitemaps.Sitemap):
    priority = 0.5
    changefreq = 'daily'

    def items(self):
        return ['main', 'about', 'license']

    def location(self, item):
        return reverse(item)

# urls.py
from django.conf.urls import url
from django.contrib.sitemaps.views import sitemap

from .sitemaps import StaticViewSitemap
from . import views

sitemaps = {
    'static': StaticViewSitemap,
}

urlpatterns = [
    url(r'^$', views.main, name='main'),
    url(r'^about/$', views.about, name='about'),
    url(r'^license/$', views.license, name='license'),
    # ...
    url(r'^sitemap\.xml$', sitemap, {'sitemaps': sitemaps},
        name='django.contrib.sitemaps.views.sitemap')
]

```

## Creating a sitemap index

```
views.index(request, sitemaps, template_name='sitemap_index.xml', content_type='application/xml',
            sitemap_url_name='django.contrib.sitemaps.views.sitemap')
```

The sitemap framework also has the ability to create a sitemap index that references individual sitemap files, one per each section defined in your sitemaps dictionary. The only differences in usage are:

- You use two views in your URLconf: `django.contrib.sitemaps.views.index()` and `django.contrib.sitemaps.views.sitemap()`.
- The `django.contrib.sitemaps.views.sitemap()` view should take a section keyword argument.

Here's what the relevant URLconf lines would look like for the example above:

```

from django.contrib.sitemaps import views

urlpatterns = [
    url(r'^sitemap\.xml$', views.index, {'sitemaps': sitemaps}),
    url(r'^sitemap-(?P<section>+)\.xml$', views.sitemap, {'sitemaps': sitemaps},
        name='django.contrib.sitemaps.views.sitemap'),
]

```

This will automatically generate a `sitemap.xml` file that references both `sitemap-flatpages.xml` and `sitemap-blog.xml`. The *Sitemap* classes and the sitemaps dict don't change at all.

You should create an index file if one of your sitemaps has more than 50,000 URLs. In this case, Django will automatically paginate the sitemap, and the index will reflect that.

If you're not using the vanilla sitemap view – for example, if it's wrapped with a caching decorator – you must name your sitemap view and pass `sitemap_url_name` to the index view:

```
from django.contrib.sitemaps import views as sitemaps_views
from django.views.decorators.cache import cache_page

urlpatterns = [
    url(r'^sitemap\.xml$',
        cache_page(86400)(sitemaps_views.index),
        {'sitemaps': sitemaps, 'sitemap_url_name': 'sitemaps'}),
    url(r'^sitemap-(?P<section>+)\.xml$',
        cache_page(86400)(sitemaps_views.sitemap),
        {'sitemaps': sitemaps, 'name': 'sitemaps'}),
]
```

## Template customization

If you wish to use a different template for each sitemap or sitemap index available on your site, you may specify it by passing a `template_name` parameter to the `sitemap` and `index` views via the URLconf:

```
from django.contrib.sitemaps import views

urlpatterns = [
    url(r'^custom-sitemap\.xml$', views.index, {
        'sitemaps': sitemaps,
        'template_name': 'custom_sitemap.html'
    }),
    url(r'^custom-sitemap-(?P<section>+)\.xml$', views.sitemap, {
        'sitemaps': sitemaps,
        'template_name': 'custom_sitemap.html'
    }, name='django.contrib.sitemaps.views.sitemap'),
]
```

These views return `TemplateResponse` instances which allow you to easily customize the response data before rendering. For more details, see the [TemplateResponse documentation](#).

## Context variables

When customizing the templates for the `index()` and `sitemap()` views, you can rely on the following context variables.

### Index

The variable `sitemaps` is a list of absolute URLs to each of the sitemaps.

### Sitemap

The variable `urlset` is a list of URLs that should appear in the sitemap. Each URL exposes attributes as defined in the `Sitemap` class:

- `changefreq`
- `item`
- `lastmod`
- `location`
- `priority`

The `item` attribute has been added for each URL to allow more flexible customization of the templates, such as Google news sitemaps. Assuming Sitemap’s `items()` would return a list of items with `publication_data` and a `tags` field something like this would generate a Google News compatible sitemap:

```
<?xml version="1.0" encoding="UTF-8"?>
<urlset
  xmlns="http://www.sitemaps.org/schemas/sitemap/0.9"
  xmlns:news="http://www.google.com/schemas/sitemap-news/0.9">
{% spaceless %}
{% for url in urlset %}
  <url>
    <loc>{{ url.location }}</loc>
    {% if url.lastmod %}<lastmod>{{ url.lastmod|date:"Y-m-d" }}</lastmod>{% endif %}
    {% if url.changefreq %}<changefreq>{{ url.changefreq }}</changefreq>{% endif %}
    {% if url.priority %}<priority>{{ url.priority }}</priority>{% endif %}
    <news:news>
      {% if url.item.publication_date %}<news:publication_date>{{ url.item.
→publication_date|date:"Y-m-d" }}</news:publication_date>{% endif %}
      {% if url.item.tags %}<news:keywords>{{ url.item.tags }}</news:keywords>{%_
→endif %}
    </news:news>
  </url>
{% endfor %}
{% endspaceless %}
</urlset>
```

## Pinging Google

You may want to “ping” Google when your sitemap changes, to let it know to reindex your site. The sitemaps framework provides a function to do just that: `django.contrib.sitemaps.ping_google()`.

### `ping_google()`

`ping_google()` takes an optional argument, `sitemap_url`, which should be the absolute path to your site’s sitemap (e.g., `'/sitemap.xml'`). If this argument isn’t provided, `ping_google()` will attempt to figure out your sitemap by performing a reverse looking in your URLconf.

`ping_google()` raises the exception `django.contrib.sitemaps.SitemapNotFound` if it cannot determine your sitemap URL.

---

## Register with Google first!

The `ping_google()` command only works if you have registered your site with Google Webmaster Tools.

---

One useful way to call `ping_google()` is from a model’s `save()` method:

```
from django.contrib.sitemaps import ping_google

class Entry(models.Model):
```

```
# ...
def save(self, force_insert=False, force_update=False):
    super(Entry, self).save(force_insert, force_update)
    try:
        ping_google()
    except Exception:
        # Bare 'except' because we could get a variety
        # of HTTP-related exceptions.
        pass
```

A more efficient solution, however, would be to call `ping_google()` from a cron script, or some other scheduled task. The function makes an HTTP request to Google’s servers, so you may not want to introduce that network overhead each time you call `save()`.

### Pinging Google via `manage.py`

```
django-admin ping_google [sitemap_url]
```

Once the sitemaps application is added to your project, you may also ping Google using the `ping_google` management command:

```
python manage.py ping_google [/sitemap.xml]
```

## 6.5.11 The “sites” framework

Django comes with an optional “sites” framework. It’s a hook for associating objects and functionality to particular websites, and it’s a holding place for the domain names and “verbose” names of your Django-powered sites.

Use it if your single Django installation powers more than one site and you need to differentiate between those sites in some way.

The sites framework is mainly based on a simple model:

```
class models.Site
```

A model for storing the domain and name attributes of a website.

**domain**

The fully qualified domain name associated with the website. For example, `www.example.com`.

The domain field was set to be *unique*.

**name**

A human-readable “verbose” name for the website.

The `SITE_ID` setting specifies the database ID of the `Site` object associated with that particular settings file. If the setting is omitted, the `get_current_site()` function will try to get the current site by comparing the `domain` with the host name from the `request.get_host()` method.

How you use this is up to you, but Django uses it in a couple of ways automatically via simple conventions.

### Example usage

Why would you use sites? It’s best explained through examples.

## Associating content with multiple sites

The Django-powered sites [LJWorld.com](#) and [Lawrence.com](#) are operated by the same news organization – the Lawrence Journal-World newspaper in Lawrence, Kansas. LJWorld.com focuses on news, while Lawrence.com focuses on local entertainment. But sometimes editors want to publish an article on *both* sites.

The naive way of solving the problem would be to require site producers to publish the same story twice: once for LJWorld.com and again for Lawrence.com. But that’s inefficient for site producers, and it’s redundant to store multiple copies of the same story in the database.

The better solution is simple: Both sites use the same article database, and an article is associated with one or more sites. In Django model terminology, that’s represented by a *ManyToManyField* in the `Article` model:

```
from django.db import models
from django.contrib.sites.models import Site

class Article(models.Model):
    headline = models.CharField(max_length=200)
    # ...
    sites = models.ManyToManyField(Site)
```

This accomplishes several things quite nicely:

- It lets the site producers edit all content – on both sites – in a single interface (the Django admin).
- It means the same story doesn’t have to be published twice in the database; it only has a single record in the database.
- It lets the site developers use the same Django view code for both sites. The view code that displays a given story just checks to make sure the requested story is on the current site. It looks something like this:

```
from django.contrib.sites.shortcuts import get_current_site

def article_detail(request, article_id):
    try:
        a = Article.objects.get(id=article_id, sites__id=get_current_
→site(request).id)
    except Article.DoesNotExist:
        raise Http404("Article does not exist on this site")
    # ...
```

## Associating content with a single site

Similarly, you can associate a model to the `Site` model in a many-to-one relationship, using *ForeignKey*.

For example, if an article is only allowed on a single site, you’d use a model like this:

```
from django.db import models
from django.contrib.sites.models import Site

class Article(models.Model):
    headline = models.CharField(max_length=200)
    # ...
    site = models.ForeignKey(Site, on_delete=models.CASCADE)
```

This has the same benefits as described in the last section.

## Hooking into the current site from views

You can use the sites framework in your Django views to do particular things based on the site in which the view is being called. For example:

```
from django.conf import settings

def my_view(request):
    if settings.SITE_ID == 3:
        # Do something.
        pass
    else:
        # Do something else.
        pass
```

Of course, it's ugly to hard-code the site IDs like that. This sort of hard-coding is best for hackish fixes that you need done quickly. The cleaner way of accomplishing the same thing is to check the current site's domain:

```
from django.contrib.sites.shortcuts import get_current_site

def my_view(request):
    current_site = get_current_site(request)
    if current_site.domain == 'foo.com':
        # Do something
        pass
    else:
        # Do something else.
        pass
```

This has also the advantage of checking if the sites framework is installed, and return a *RequestSite* instance if it is not.

If you don't have access to the request object, you can use the `get_current()` method of the *Site* model's manager. You should then ensure that your settings file does contain the *SITE\_ID* setting. This example is equivalent to the previous one:

```
from django.contrib.sites.models import Site

def my_function_without_request():
    current_site = Site.objects.get_current()
    if current_site.domain == 'foo.com':
        # Do something
        pass
    else:
        # Do something else.
        pass
```

## Getting the current domain for display

LJWorld.com and Lawrence.com both have email alert functionality, which lets readers sign up to get notifications when news happens. It's pretty basic: A reader signs up on a Web form and immediately gets an email saying, "Thanks for your subscription."

It'd be inefficient and redundant to implement this sign up processing code twice, so the sites use the same code behind the scenes. But the "thank you for signing up" notice needs to be different for each site. By using *Site* objects, we can abstract the "thank you" notice to use the values of the current site's *name* and *domain*.

Here's an example of what the form-handling view looks like:

```

from django.contrib.sites.shortcuts import get_current_site
from django.core.mail import send_mail

def register_for_newsletter(request):
    # Check form values, etc., and subscribe the user.
    # ...

    current_site = get_current_site(request)
    send_mail(
        'Thanks for subscribing to %s alerts' % current_site.name,
        'Thanks for your subscription. We appreciate it.\n\n-The %s team.' % (
            current_site.name,
        ),
        'editor@%s' % current_site.domain,
        [user.email],
    )

    # ...

```

On Lawrence.com, this email has the subject line “Thanks for subscribing to lawrence.com alerts.” On LJWorld.com, the email has the subject “Thanks for subscribing to LJWorld.com alerts.” Same goes for the email’s message body.

Note that an even more flexible (but more heavyweight) way of doing this would be to use Django’s template system. Assuming Lawrence.com and LJWorld.com have different template directories (*DIRS*), you could simply farm out to the template system like so:

```

from django.core.mail import send_mail
from django.template import loader, Context

def register_for_newsletter(request):
    # Check form values, etc., and subscribe the user.
    # ...

    subject = loader.get_template('alerts/subject.txt').render(Context({}))
    message = loader.get_template('alerts/message.txt').render(Context({}))
    send_mail(subject, message, 'editor@ljworld.com', [user.email])

    # ...

```

In this case, you’d have to create `subject.txt` and `message.txt` template files for both the LJWorld.com and Lawrence.com template directories. That gives you more flexibility, but it’s also more complex.

It’s a good idea to exploit the *Site* objects as much as possible, to remove unneeded complexity and redundancy.

## Getting the current domain for full URLs

Django’s `get_absolute_url()` convention is nice for getting your objects’ URL without the domain name, but in some cases you might want to display the full URL – with `http://` and the domain and everything – for an object. To do this, you can use the sites framework. A simple example:

```

>>> from django.contrib.sites.models import Site
>>> obj = MyModel.objects.get(id=3)
>>> obj.get_absolute_url()
'/mymodel/objects/3/'
>>> Site.objects.get_current().domain

```

```
'example.com'  
>>> 'https://%s%s' % (Site.objects.get_current().domain, obj.get_absolute_url())  
'https://example.com/mymodel/objects/3/'
```

## Enabling the sites framework

To enable the sites framework, follow these steps:

1. Add `'django.contrib.sites'` to your `INSTALLED_APPS` setting.
2. Define a `SITE_ID` setting:

```
SITE_ID = 1
```

3. Run `migrate`.

`django.contrib.sites` registers a `post_migrate` signal handler which creates a default site named `example.com` with the domain `example.com`. This site will also be created after Django creates the test database. To set the correct name and domain for your project, you can use a *data migration*.

In order to serve different sites in production, you'd create a separate settings file with each `SITE_ID` (perhaps importing from a common settings file to avoid duplicating shared settings) and then specify the appropriate `DJANGO_SETTINGS_MODULE` for each site.

## Caching the current Site object

As the current site is stored in the database, each call to `Site.objects.get_current()` could result in a database query. But Django is a little cleverer than that: on the first request, the current site is cached, and any subsequent call returns the cached data instead of hitting the database.

If for any reason you want to force a database query, you can tell Django to clear the cache using `Site.objects.clear_cache()`:

```
# First call; current site fetched from database.  
current_site = Site.objects.get_current()  
# ...  
  
# Second call; current site fetched from cache.  
current_site = Site.objects.get_current()  
# ...  
  
# Force a database query for the third call.  
Site.objects.clear_cache()  
current_site = Site.objects.get_current()
```

## The CurrentSiteManager

```
class managers.CurrentSiteManager
```

If `Site` plays a key role in your application, consider using the helpful `CurrentSiteManager` in your model(s). It's a model *manager* that automatically filters its queries to include only objects associated with the current `Site`.

---

## Mandatory SITE\_ID

The `CurrentSiteManager` is only usable when the `SITE_ID` setting is defined in your settings.

Use `CurrentSiteManager` by adding it to your model explicitly. For example:

```
from django.db import models
from django.contrib.sites.models import Site
from django.contrib.sites.managers import CurrentSiteManager

class Photo(models.Model):
    photo = models.FileField(upload_to='/home/photos')
    photographer_name = models.CharField(max_length=100)
    pub_date = models.DateField()
    site = models.ForeignKey(Site, on_delete=models.CASCADE)
    objects = models.Manager()
    on_site = CurrentSiteManager()
```

With this model, `Photo.objects.all()` will return all `Photo` objects in the database, but `Photo.on_site.all()` will return only the `Photo` objects associated with the current site, according to the `SITE_ID` setting.

Put another way, these two statements are equivalent:

```
Photo.objects.filter(site=settings.SITE_ID)
Photo.on_site.all()
```

How did `CurrentSiteManager` know which field of `Photo` was the `Site`? By default, `CurrentSiteManager` looks for either a `ForeignKey` called `site` or a `ManyToManyField` called `sites` to filter on. If you use a field named something other than `site` or `sites` to identify which `Site` objects your object is related to, then you need to explicitly pass the custom field name as a parameter to `CurrentSiteManager` on your model. The following model, which has a field called `publish_on`, demonstrates this:

```
from django.db import models
from django.contrib.sites.models import Site
from django.contrib.sites.managers import CurrentSiteManager

class Photo(models.Model):
    photo = models.FileField(upload_to='/home/photos')
    photographer_name = models.CharField(max_length=100)
    pub_date = models.DateField()
    publish_on = models.ForeignKey(Site, on_delete=models.CASCADE)
    objects = models.Manager()
    on_site = CurrentSiteManager('publish_on')
```

If you attempt to use `CurrentSiteManager` and pass a field name that doesn't exist, Django will raise a `ValueError`.

Finally, note that you'll probably want to keep a normal (non-site-specific) `Manager` on your model, even if you use `CurrentSiteManager`. As explained in the [manager documentation](#), if you define a manager manually, then Django won't create the automatic `objects = models.Manager()` manager for you. Also note that certain parts of Django – namely, the Django admin site and generic views – use whichever manager is defined *first* in the model, so if you want your admin site to have access to all objects (not just site-specific ones), put `objects = models.Manager()` in your model, before you define `CurrentSiteManager`.

## Site middleware

If you often use this pattern:

```
from django.contrib.sites.models import Site

def my_view(request):
    site = Site.objects.get_current()
    ...
```

there is simple way to avoid repetitions. Add `django.contrib.sites.middleware.CurrentSiteMiddleware` to `MIDDLEWARE`. The middleware sets the `site` attribute on every request object, so you can use `request.site` to get the current site.

## How Django uses the sites framework

Although it's not required that you use the sites framework, it's strongly encouraged, because Django takes advantage of it in a few places. Even if your Django installation is powering only a single site, you should take the two seconds to create the site object with your domain and name, and point to its ID in your `SITE_ID` setting.

Here's how Django uses the sites framework:

- In the *redirects framework*, each redirect object is associated with a particular site. When Django searches for a redirect, it takes into account the current site.
- In the *flatpages framework*, each flatpage is associated with a particular site. When a flatpage is created, you specify its *Site*, and the *FlatpageFallbackMiddleware* checks the current site in retrieving flatpages to display.
- In the *syndication framework*, the templates for `title` and `description` automatically have access to a variable `{{ site }}`, which is the *Site* object representing the current site. Also, the hook for providing item URLs will use the domain from the current *Site* object if you don't specify a fully-qualified domain.
- In the *authentication framework*, the `django.contrib.auth.views.login()` view passes the current *Site* name to the template as `{{ site_name }}`.
- The shortcut view (`django.contrib.contenttypes.views.shortcut`) uses the domain of the current *Site* object when calculating an object's URL.
- In the admin framework, the "view on site" link uses the current *Site* to work out the domain for the site that it will redirect to.

## RequestSite objects

Some *django.contrib* applications take advantage of the sites framework but are architected in a way that doesn't require the sites framework to be installed in your database. (Some people don't want to, or just aren't able to install the extra database table that the sites framework requires.) For those cases, the framework provides a *django.contrib.sites.requests.RequestSite* class, which can be used as a fallback when the database-backed sites framework is not available.

### `class requests.RequestSite`

A class that shares the primary interface of *Site* (i.e., it has `domain` and `name` attributes) but gets its data from a Django *HttpRequest* object rather than from a database.

`__init__(request)`

Sets the name and domain attributes to the value of `get_host()`.

A *RequestSite* object has a similar interface to a normal *Site* object, except its `__init__()` method takes an *HttpRequest* object. It's able to deduce the domain and name by looking at the request's domain. It has `save()` and `delete()` methods to match the interface of *Site*, but the methods raise `NotImplementedError`.

### get\_current\_site shortcut

Finally, to avoid repetitive fallback code, the framework provides a `django.contrib.sites.shortcuts.get_current_site()` function.

`shortcuts.get_current_site(request)`

A function that checks if `django.contrib.sites` is installed and returns either the current `Site` object or a `RequestSite` object based on the request. It looks up the current site based on `request.get_host()` if the `SITE_ID` setting is not defined.

Both a domain and a port may be returned by `request.get_host()` when the Host header has a port explicitly specified, e.g. `example.com:80`. In such cases, if the lookup fails because the host does not match a record in the database, the port is stripped and the lookup is retried with the domain part only. This does not apply to `RequestSite` which will always use the unmodified host.

Retrying the lookup with the port stripped was added.

## 6.5.12 The staticfiles app

`django.contrib.staticfiles` collects static files from each of your applications (and any other places you specify) into a single location that can easily be served in production.

### See also:

For an introduction to the static files app and some usage examples, see *Managing static files (e.g. images, JavaScript, CSS)*. For guidelines on deploying static files, see *Deploying static files*.

### Settings

See *staticfiles settings* for details on the following settings:

- `STATIC_ROOT`
- `STATIC_URL`
- `STATICFILES_DIRS`
- `STATICFILES_STORAGE`
- `STATICFILES_FINDERS`

### Management Commands

`django.contrib.staticfiles` exposes three management commands.

#### `collectstatic`

##### `django-admin collectstatic`

Collects the static files into `STATIC_ROOT`.

Duplicate file names are by default resolved in a similar way to how template resolution works: the file that is first found in one of the specified locations will be used. If you're confused, the `findstatic` command can help show you which files are found.

On subsequent `collectstatic` runs (if `STATIC_ROOT` isn't empty), files are copied only if they have a modified timestamp greater than the timestamp of the file in `STATIC_ROOT`. Therefore if you remove an application from

`INSTALLED_APPS`, it's a good idea to use the `collectstatic --clear` option in order to remove stale static files.

Files are searched by using the *enabled finders*. The default is to look in all locations defined in `STATICFILES_DIRS` and in the 'static' directory of apps specified by the `INSTALLED_APPS` setting.

The `collectstatic` management command calls the `post_process()` method of the `STATICFILES_STORAGE` after each run and passes a list of paths that have been found by the management command. It also receives all command line options of `collectstatic`. This is used by the `CachedStaticFilesStorage` by default.

By default, collected files receive permissions from `FILE_UPLOAD_PERMISSIONS` and collected directories receive permissions from `FILE_UPLOAD_DIRECTORY_PERMISSIONS`. If you would like different permissions for these files and/or directories, you can subclass either of the *static files storage classes* and specify the `file_permissions_mode` and/or `directory_permissions_mode` parameters, respectively. For example:

```
from django.contrib.staticfiles import storage

class MyStaticFilesStorage(storage.StaticFilesStorage):
    def __init__(self, *args, **kwargs):
        kwargs['file_permissions_mode'] = 0o640
        kwargs['directory_permissions_mode'] = 0o760
        super(MyStaticFilesStorage, self).__init__(*args, **kwargs)
```

Then set the `STATICFILES_STORAGE` setting to 'path.to.MyStaticFilesStorage'.

Some commonly used options are:

**--noinput, --no-input**

Do NOT prompt the user for input of any kind.

The `--no-input` alias was added.

**--ignore PATTERN, -i PATTERN**

Ignore files or directories matching this glob-style pattern. Use multiple times to ignore more.

**--dry-run, -n**

Do everything except modify the filesystem.

**--clear, -c**

Clear the existing files before trying to copy or link the original file.

**--link, -l**

Create a symbolic link to each file instead of copying.

**--no-post-process**

Don't call the `post_process()` method of the configured `STATICFILES_STORAGE` storage backend.

**--no-default-ignore**

Don't ignore the common private glob-style patterns 'CVS', '.\*' and '\*~'.

For a full list of options, refer to the commands own help by running:

```
$ python manage.py collectstatic --help
```

## Customizing the ignored pattern list

The default ignored pattern list, ['CVS', '.\*', '\*~'], can be customized in a more persistent way than providing the `--ignore` command option at each `collectstatic` invocation. Provide a custom `AppConfig` class,

override the `ignore_patterns` attribute of this class and replace `'django.contrib.staticfiles'` with that class path in your `INSTALLED_APPS` setting:

```
from django.contrib.staticfiles.apps import StaticFilesConfig

class MyStaticFilesConfig(StaticFilesConfig):
    ignore_patterns = [...] # your custom ignore list
```

## findstatic

### django-admin findstatic staticfile [staticfile ...]

Searches for one or more relative paths with the enabled finders.

For example:

```
$ python manage.py findstatic css/base.css admin/js/core.js
Found 'css/base.css' here:
  /home/special.polls.com/core/static/css/base.css
  /home/polls.com/core/static/css/base.css
Found 'admin/js/core.js' here:
  /home/polls.com/src/django/contrib/admin/media/js/core.js
```

### findstatic --first

By default, all matching locations are found. To only return the first match for each relative path, use the `--first` option:

```
$ python manage.py findstatic css/base.css --first
Found 'css/base.css' here:
  /home/special.polls.com/core/static/css/base.css
```

This is a debugging aid; it'll show you exactly which static file will be collected for a given path.

By setting the `--verbosity` flag to 0, you can suppress the extra output and just get the path names:

```
$ python manage.py findstatic css/base.css --verbosity 0
/home/special.polls.com/core/static/css/base.css
/home/polls.com/core/static/css/base.css
```

On the other hand, by setting the `--verbosity` flag to 2, you can get all the directories which were searched:

```
$ python manage.py findstatic css/base.css --verbosity 2
Found 'css/base.css' here:
  /home/special.polls.com/core/static/css/base.css
  /home/polls.com/core/static/css/base.css
Looking in the following locations:
  /home/special.polls.com/core/static
  /home/polls.com/core/static
  /some/other/path/static
```

## runserver

### django-admin runserver [addrport]

Overrides the core `runserver` command if the `staticfiles` app is *installed* and adds automatic serving of static files and the following new options.

**--nostatic**

Use the `--nostatic` option to disable serving of static files with the `staticfiles` app entirely. This option is only available if the `staticfiles` app is in your project's `INSTALLED_APPS` setting.

Example usage:

```
django-admin runserver --nostatic
```

**--insecure**

Use the `--insecure` option to force serving of static files with the `staticfiles` app even if the `DEBUG` setting is `False`. By using this you acknowledge the fact that it's **grossly inefficient** and probably **insecure**. This is only intended for local development, should **never be used in production** and is only available if the `staticfiles` app is in your project's `INSTALLED_APPS` setting. `runserver --insecure` doesn't work with `CachedStaticFilesStorage`.

Example usage:

```
django-admin runserver --insecure
```

## Storages

### StaticFilesStorage

**class** `storage.StaticFilesStorage`

A subclass of the `FileSystemStorage` storage backend that uses the `STATIC_ROOT` setting as the base file system location and the `STATIC_URL` setting respectively as the base URL.

`storage.StaticFilesStorage.post_process` (*paths*, *\*\*options*)

This method is called by the `collectstatic` management command after each run and gets passed the local storages and paths of found files as a dictionary, as well as the command line options.

The `CachedStaticFilesStorage` uses this behind the scenes to replace the paths with their hashed counterparts and update the cache appropriately.

### ManifestStaticFilesStorage

**class** `storage.ManifestStaticFilesStorage`

A subclass of the `StaticFilesStorage` storage backend which stores the file names it handles by appending the MD5 hash of the file's content to the filename. For example, the file `css/styles.css` would also be saved as `css/styles.55e7cbb9ba48.css`.

The purpose of this storage is to keep serving the old files in case some pages still refer to those files, e.g. because they are cached by you or a 3rd party proxy server. Additionally, it's very helpful if you want to apply [far future Expires headers](#) to the deployed files to speed up the load time for subsequent page visits.

The storage backend automatically replaces the paths found in the saved files matching other saved files with the path of the cached copy (using the `post_process()` method). The regular expressions used to find those paths (`django.contrib.staticfiles.storage.HashedFilesMixin.patterns`) by default covers the `@import` rule and `url()` statement of [Cascading Style Sheets](#). For example, the `'css/styles.css'` file with the content

```
@import url("../admin/css/base.css");
```

would be replaced by calling the `url()` method of the `ManifestStaticFilesStorage` storage backend, ultimately saving a `'css/styles.55e7cbb9ba48.css'` file with the following content:

```
@import url("../admin/css/base.27e20196a850.css");
```

To enable the `ManifestStaticFilesStorage` you have to make sure the following requirements are met:

- the `STATICFILES_STORAGE` setting is set to `'django.contrib.staticfiles.storage.ManifestStaticFilesStorage'`
- the `DEBUG` setting is set to `False`
- you've collected all your static files by using the `collectstatic` management command

In older versions, you also had to use `{% load static from staticfiles %}` in your template. The `static` template tag (`{% load static %}`) now uses `django.contrib.staticfiles` if it's installed.

Since creating the MD5 hash can be a performance burden to your website during runtime, `staticfiles` will automatically store the mapping with hashed names for all processed files in a file called `staticfiles.json`. This happens once when you run the `collectstatic` management command.

Due to the requirement of running `collectstatic`, this storage typically shouldn't be used when running tests as `collectstatic` isn't run as part of the normal test setup. During testing, ensure that the `STATICFILES_STORAGE` setting is set to something else like `'django.contrib.staticfiles.storage.StaticFilesStorage'` (the default).

`storage.ManifestStaticFilesStorage.file_hash(name, content=None)`

The method that is used when creating the hashed name of a file. Needs to return a hash for the given file name and content. By default it calculates a MD5 hash from the content's chunks as mentioned above. Feel free to override this method to use your own hashing algorithm.

### CachedStaticFilesStorage

**class** `storage.CachedStaticFilesStorage`

`CachedStaticFilesStorage` is a similar class like the `ManifestStaticFilesStorage` class but uses Django's *caching framework* for storing the hashed names of processed files instead of a static manifest file called `staticfiles.json`. This is mostly useful for situations in which you don't have access to the file system.

If you want to override certain options of the cache backend the storage uses, simply specify a custom entry in the `CACHES` setting named `'staticfiles'`. It falls back to using the `'default'` cache backend.

### Finders Module

`staticfiles` finders has a `searched_locations` attribute which is a list of directory paths in which the finders searched. Example usage:

```
from django.contrib.staticfiles import finders

result = finders.find('css/base.css')
searched_locations = finders.searched_locations
```

### Other Helpers

There are a few other helpers outside of the `staticfiles` app to work with static files:

- The `django.template.context_processors.static()` context processor which adds `STATIC_URL` to every template context rendered with `RequestContext` contexts.
- The builtin template tag `static` which takes a path and urljoins it with the static prefix `STATIC_URL`. If `django.contrib.staticfiles` is installed, the tag uses the `url()` method of the `STATICFILES_STORAGE` instead.
- The builtin template tag `get_static_prefix` which populates a template variable with the static prefix `STATIC_URL` to be used as a variable or directly.
- The similar template tag `get_media_prefix` which works like `get_static_prefix` but uses `MEDIA_URL`.

## Static file development view

The static files tools are mostly designed to help with getting static files successfully deployed into production. This usually means a separate, dedicated static file server, which is a lot of overhead to mess with when developing locally. Thus, the `staticfiles` app ships with a **quick and dirty helper view** that you can use to serve files locally in development.

```
views.serve(request, path)
```

This view function serves static files in development.

**Warning:** This view will only work if `DEBUG` is `True`.

That's because this view is **grossly inefficient** and probably **insecure**. This is only intended for local development, and should **never be used in production**.

---

**Note:** To guess the served files' content types, this view relies on the `mimetypes` module from the Python standard library, which itself relies on the underlying platform's map files. If you find that this view doesn't return proper content types for certain files, it is most likely that the platform's map files need to be updated. This can be achieved, for example, by installing or updating the `mailcap` package on a Red Hat distribution, or `mime-support` on a Debian distribution.

---

This view is automatically enabled by `runserver` (with a `DEBUG` setting set to `True`). To use the view with a different local development server, add the following snippet to the end of your primary URL configuration:

```
from django.conf import settings
from django.contrib.staticfiles import views

if settings.DEBUG:
    urlpatterns += [
        url(r'^static/(?P<path>.*)$', views.serve),
    ]
```

Note, the beginning of the pattern (`r'^static/'`) should be your `STATIC_URL` setting.

Since this is a bit finicky, there's also a helper function that'll do this for you:

```
urls.staticfiles_urlpatterns()
```

This will return the proper URL pattern for serving static files to your already defined pattern list. Use it like this:

```

from django.contrib.staticfiles.urls import staticfiles_urlpatterns

# ... the rest of your URLconf here ...

urlpatterns += staticfiles_urlpatterns()

```

This will inspect your `STATIC_URL` setting and wire up the view to serve static files accordingly. Don't forget to set the `STATICFILES_DIRS` setting appropriately to let `django.contrib.staticfiles` know where to look for files in addition to files in app directories.

**Warning:** This helper function will only work if `DEBUG` is `True` and your `STATIC_URL` setting is neither empty nor a full URL such as `http://static.example.com/`.

That's because this view is **grossly inefficient** and probably **insecure**. This is only intended for local development, and should **never be used in production**.

### Specialized test case to support 'live testing'

```
class testing.StaticLiveServerTestCase
```

This unittest `TestCase` subclass extends `django.test.LiveServerTestCase`.

Just like its parent, you can use it to write tests that involve running the code under test and consuming it with testing tools through HTTP (e.g. Selenium, PhantomJS, etc.), because of which it's needed that the static assets are also published.

But given the fact that it makes use of the `django.contrib.staticfiles.views.serve()` view described above, it can transparently overlay at test execution-time the assets provided by the `staticfiles` finders. This means you don't need to run `collectstatic` before or as a part of your tests setup.

## 6.5.13 The syndication feed framework

Django comes with a high-level syndication-feed-generating framework that makes creating `RSS` and `Atom` feeds easy.

To create any syndication feed, all you have to do is write a short Python class. You can create as many feeds as you want.

Django also comes with a lower-level feed-generating API. Use this if you want to generate feeds outside of a Web context, or in some other lower-level way.

### The high-level framework

#### Overview

The high-level feed-generating framework is supplied by the `Feed` class. To create a feed, write a `Feed` class and point to an instance of it in your `URLconf`.

## Feed classes

A *Feed* class is a Python class that represents a syndication feed. A feed can be simple (e.g., a “site news” feed, or a basic feed displaying the latest entries of a blog) or more complex (e.g., a feed displaying all the blog entries in a particular category, where the category is variable).

Feed classes subclass `django.contrib.syndication.views.Feed`. They can live anywhere in your code-base.

Instances of *Feed* classes are views which can be used in your *URLconf*.

## A simple example

This simple example, taken from a hypothetical police beat news site describes a feed of the latest five news items:

```
from django.contrib.syndication.views import Feed
from django.urls import reverse
from policebeat.models import NewsItem

class LatestEntriesFeed(Feed):
    title = "Police beat site news"
    link = "/sitenews/"
    description = "Updates on changes and additions to police beat central."

    def items(self):
        return NewsItem.objects.order_by('-pub_date')[:5]

    def item_title(self, item):
        return item.title

    def item_description(self, item):
        return item.description

    # item_link is only needed if NewsItem has no get_absolute_url method.
    def item_link(self, item):
        return reverse('news-item', args=[item.pk])
```

To connect a URL to this feed, put an instance of the Feed object in your *URLconf*. For example:

```
from django.conf.urls import url
from myproject.feeds import LatestEntriesFeed

urlpatterns = [
    # ...
    url(r'^latest/feed/$', LatestEntriesFeed()),
    # ...
]
```

Note:

- The Feed class subclasses `django.contrib.syndication.views.Feed`.
- `title`, `link` and `description` correspond to the standard RSS `<title>`, `<link>` and `<description>` elements, respectively.
- `items()` is, simply, a method that returns a list of objects that should be included in the feed as `<item>` elements. Although this example returns `NewsItem` objects using Django’s *object-relational mapper*, `items()`

doesn't have to return model instances. Although you get a few bits of functionality "for free" by using Django models, `items()` can return any type of object you want.

- If you're creating an Atom feed, rather than an RSS feed, set the `subtitle` attribute instead of the `description` attribute. See *Publishing Atom and RSS feeds in tandem*, later, for an example.

One thing is left to do. In an RSS feed, each `<item>` has a `<title>`, `<link>` and `<description>`. We need to tell the framework what data to put into those elements.

- For the contents of `<title>` and `<description>`, Django tries calling the methods `item_title()` and `item_description()` on the `Feed` class. They are passed a single parameter, `item`, which is the object itself. These are optional; by default, the unicode representation of the object is used for both.

If you want to do any special formatting for either the title or description, *Django templates* can be used instead. Their paths can be specified with the `title_template` and `description_template` attributes on the `Feed` class. The templates are rendered for each item and are passed two template context variables:

- `{{ obj }}` – The current object (one of whichever objects you returned in `items()`).
- `{{ site }}` – A `django.contrib.sites.models.Site` object representing the current site. This is useful for `{{ site.domain }}` or `{{ site.name }}`. If you do *not* have the Django sites framework installed, this will be set to a `RequestSite` object. See the *RequestSite section of the sites framework documentation* for more.

See *a complex example* below that uses a description template.

`Feed.get_context_data(**kwargs)`

There is also a way to pass additional information to title and description templates, if you need to supply more than the two variables mentioned before. You can provide your implementation of `get_context_data` method in your `Feed` subclass. For example:

```
from mysite.models import Article
from django.contrib.syndication.views import Feed

class ArticlesFeed(Feed):
    title = "My articles"
    description_template = "feeds/articles.html"

    def items(self):
        return Article.objects.order_by('-pub_date')[:5]

    def get_context_data(self, **kwargs):
        context = super(ArticlesFeed, self).get_context_data(**kwargs)
        context['foo'] = 'bar'
        return context
```

And the template:

```
Something about {{ foo }}: {{ obj.description }}
```

This method will be called once per each item in the list returned by `items()` with the following keyword arguments:

- `item`: the current item. For backward compatibility reasons, the name of this context variable is `{{ obj }}`.
- `obj`: the object returned by `get_object()`. By default this is not exposed to the templates to avoid confusion with `{{ obj }}` (see above), but you can use it in your implementation of `get_context_data()`.
- `site`: current site as described above.

- request: current request.

The behavior of `get_context_data()` mimics that of *generic views* - you're supposed to call `super()` to retrieve context data from parent class, add your data and return the modified dictionary.

- To specify the contents of `<link>`, you have two options. For each item in `items()`, Django first tries calling the `item_link()` method on the `Feed` class. In a similar way to the title and description, it is passed it a single parameter, `item`. If that method doesn't exist, Django tries executing a `get_absolute_url()` method on that object. Both `get_absolute_url()` and `item_link()` should return the item's URL as a normal Python string. As with `get_absolute_url()`, the result of `item_link()` will be included directly in the URL, so you are responsible for doing all necessary URL quoting and conversion to ASCII inside the method itself.

## A complex example

The framework also supports more complex feeds, via arguments.

For example, a website could offer an RSS feed of recent crimes for every police beat in a city. It'd be silly to create a separate `Feed` class for each police beat; that would violate the *DRY principle* and would couple data to programming logic. Instead, the syndication framework lets you access the arguments passed from your `URLconf` so feeds can output items based on information in the feed's URL.

The police beat feeds could be accessible via URLs like this:

- `/beats/613/rss/` - Returns recent crimes for beat 613.
- `/beats/1424/rss/` - Returns recent crimes for beat 1424.

These can be matched with a `URLconf` line such as:

```
url(r'^beats/(?P<beat_id>[0-9]+)/rss/$', BeatFeed()),
```

Like a view, the arguments in the URL are passed to the `get_object()` method along with the request object.

Here's the code for these beat-specific feeds:

```
from django.contrib.syndication.views import Feed

class BeatFeed(Feed):
    description_template = 'feeds/beat_description.html'

    def get_object(self, request, beat_id):
        return Beat.objects.get(pk=beat_id)

    def title(self, obj):
        return "Police beat central: Crimes for beat %s" % obj.beat

    def link(self, obj):
        return obj.get_absolute_url()

    def description(self, obj):
        return "Crimes recently reported in police beat %s" % obj.beat

    def items(self, obj):
        return Crime.objects.filter(beat=obj).order_by('-crime_date')[:30]
```

To generate the feed's `<title>`, `<link>` and `<description>`, Django uses the `title()`, `link()` and `description()` methods. In the previous example, they were simple string class attributes, but this example

illustrates that they can be either strings *or* methods. For each of `title`, `link` and `description`, Django follows this algorithm:

- First, it tries to call a method, passing the `obj` argument, where `obj` is the object returned by `get_object()`.
- Failing that, it tries to call a method with no arguments.
- Failing that, it uses the class attribute.

Also note that `items()` also follows the same algorithm – first, it tries `items(obj)`, then `items()`, then finally an `items` class attribute (which should be a list).

We are using a template for the item descriptions. It can be very simple:

```
{{ obj.description }}
```

However, you are free to add formatting as desired.

The `ExampleFeed` class below gives full documentation on methods and attributes of *Feed* classes.

## Specifying the type of feed

By default, feeds produced in this framework use RSS 2.0.

To change that, add a `feed_type` attribute to your *Feed* class, like so:

```
from django.utils.feedgenerator import Atom1Feed

class MyFeed(Feed):
    feed_type = Atom1Feed
```

Note that you set `feed_type` to a class object, not an instance.

Currently available feed types are:

- `django.utils.feedgenerator.Rss201rev2Feed` (RSS 2.01. Default.)
- `django.utils.feedgenerator.RssUserland091Feed` (RSS 0.91.)
- `django.utils.feedgenerator.Atom1Feed` (Atom 1.0.)

## Enclosures

To specify enclosures, such as those used in creating podcast feeds, use the `item_enclosures` hook or, alternatively and if you only have a single enclosure per item, the `item_enclosure_url`, `item_enclosure_length`, and `item_enclosure_mime_type` hooks. See the `ExampleFeed` class below for usage examples.

Support for multiple enclosures per feed item was added through the `item_enclosures` hook.

## Language

Feeds created by the syndication framework automatically include the appropriate `<language>` tag (RSS 2.0) or `xml:lang` attribute (Atom). This comes directly from your `LANGUAGE_CODE` setting.

## URLs

The `link` method/attribute can return either an absolute path (e.g. `"/blog/"`) or a URL with the fully-qualified domain and protocol (e.g. `"https://www.example.com/blog/"`). If `link` doesn't return the domain, the syndication framework will insert the domain of the current site, according to your `SITE_ID` setting.

Atom feeds require a `<link rel="self">` that defines the feed's current location. The syndication framework populates this automatically, using the domain of the current site according to the `SITE_ID` setting.

## Publishing Atom and RSS feeds in tandem

Some developers like to make available both Atom *and* RSS versions of their feeds. That's easy to do with Django: Just create a subclass of your `Feed` class and set the `feed_type` to something different. Then update your URLconf to add the extra versions.

Here's a full example:

```
from django.contrib.syndication.views import Feed
from policebeat.models import NewsItem
from django.utils.feedgenerator import Atom1Feed

class RssSiteNewsFeed(Feed):
    title = "Police beat site news"
    link = "/sitenews/"
    description = "Updates on changes and additions to police beat central."

    def items(self):
        return NewsItem.objects.order_by('-pub_date')[:5]

class AtomSiteNewsFeed(RssSiteNewsFeed):
    feed_type = Atom1Feed
    subtitle = RssSiteNewsFeed.description
```

---

**Note:** In this example, the RSS feed uses a `description` while the Atom feed uses a `subtitle`. That's because Atom feeds don't provide for a feed-level "description," but they *do* provide for a "subtitle."

If you provide a `description` in your `Feed` class, Django will *not* automatically put that into the `subtitle` element, because a `subtitle` and `description` are not necessarily the same thing. Instead, you should define a `subtitle` attribute.

In the above example, we simply set the Atom feed's `subtitle` to the RSS feed's `description`, because it's quite short already.

---

And the accompanying URLconf:

```
from django.conf.urls import url
from myproject.feeds import RssSiteNewsFeed, AtomSiteNewsFeed

urlpatterns = [
    # ...
    url(r'^sitenews/rss/$', RssSiteNewsFeed()),
    url(r'^sitenews/atom/$', AtomSiteNewsFeed()),
    # ...
]
```

## Feed class reference

### class `views.Feed`

This example illustrates all possible attributes and methods for a *Feed* class:

```

from django.contrib.syndication.views import Feed
from django.utils import feedgenerator

class ExampleFeed(Feed):

    # FEED TYPE -- Optional. This should be a class that subclasses
    # django.utils.feedgenerator.SyndicationFeed. This designates
    # which type of feed this should be: RSS 2.0, Atom 1.0, etc. If
    # you don't specify feed_type, your feed will be RSS 2.0. This
    # should be a class, not an instance of the class.

    feed_type = feedgenerator.Rss201rev2Feed

    # TEMPLATE NAMES -- Optional. These should be strings
    # representing names of Django templates that the system should
    # use in rendering the title and description of your feed items.
    # Both are optional. If a template is not specified, the
    # item_title() or item_description() methods are used instead.

    title_template = None
    description_template = None

    # TITLE -- One of the following three is required. The framework
    # looks for them in this order.

    def title(self, obj):
        """
        Takes the object returned by get_object() and returns the
        feed's title as a normal Python string.
        """

    def title(self):
        """
        Returns the feed's title as a normal Python string.
        """

    title = 'foo' # Hard-coded title.

    # LINK -- One of the following three is required. The framework
    # looks for them in this order.

    def link(self, obj):
        """
        # Takes the object returned by get_object() and returns the URL
        # of the HTML version of the feed as a normal Python string.
        """

    def link(self):
        """
        Returns the URL of the HTML version of the feed as a normal Python
        string.
        """

```

```
link = '/blog/' # Hard-coded URL.

# FEED_URL -- One of the following three is optional. The framework
# looks for them in this order.

def feed_url(self, obj):
    """
    # Takes the object returned by get_object() and returns the feed's
    # own URL as a normal Python string.
    """

def feed_url(self):
    """
    Returns the feed's own URL as a normal Python string.
    """

feed_url = '/blog/rss/' # Hard-coded URL.

# GUID -- One of the following three is optional. The framework looks
# for them in this order. This property is only used for Atom feeds
# (where it is the feed-level ID element). If not provided, the feed
# link is used as the ID.

def feed_guid(self, obj):
    """
    Takes the object returned by get_object() and returns the globally
    unique ID for the feed as a normal Python string.
    """

def feed_guid(self):
    """
    Returns the feed's globally unique ID as a normal Python string.
    """

feed_guid = '/foo/bar/1234' # Hard-coded guid.

# DESCRIPTION -- One of the following three is required. The framework
# looks for them in this order.

def description(self, obj):
    """
    Takes the object returned by get_object() and returns the feed's
    description as a normal Python string.
    """

def description(self):
    """
    Returns the feed's description as a normal Python string.
    """

description = 'Foo bar baz.' # Hard-coded description.

# AUTHOR NAME -- One of the following three is optional. The framework
# looks for them in this order.

def author_name(self, obj):
    """
```

```

    Takes the object returned by get_object() and returns the feed's
    author's name as a normal Python string.
    """

def author_name(self):
    """
    Returns the feed's author's name as a normal Python string.
    """

author_name = 'Sally Smith' # Hard-coded author name.

# AUTHOR EMAIL --One of the following three is optional. The framework
# looks for them in this order.

def author_email(self, obj):
    """
    Takes the object returned by get_object() and returns the feed's
    author's email as a normal Python string.
    """

def author_email(self):
    """
    Returns the feed's author's email as a normal Python string.
    """

author_email = 'test@example.com' # Hard-coded author email.

# AUTHOR LINK --One of the following three is optional. The framework
# looks for them in this order. In each case, the URL should include
# the "http://" and domain name.

def author_link(self, obj):
    """
    Takes the object returned by get_object() and returns the feed's
    author's URL as a normal Python string.
    """

def author_link(self):
    """
    Returns the feed's author's URL as a normal Python string.
    """

author_link = 'https://www.example.com/' # Hard-coded author URL.

# CATEGORIES -- One of the following three is optional. The framework
# looks for them in this order. In each case, the method/attribute
# should return an iterable object that returns strings.

def categories(self, obj):
    """
    Takes the object returned by get_object() and returns the feed's
    categories as iterable over strings.
    """

def categories(self):
    """
    Returns the feed's categories as iterable over strings.
    """

```

```
categories = ("python", "django") # Hard-coded list of categories.

# COPYRIGHT NOTICE -- One of the following three is optional. The
# framework looks for them in this order.

def feed_copyright(self, obj):
    """
    Takes the object returned by get_object() and returns the feed's
    copyright notice as a normal Python string.
    """

def feed_copyright(self):
    """
    Returns the feed's copyright notice as a normal Python string.
    """

feed_copyright = 'Copyright (c) 2007, Sally Smith' # Hard-coded copyright notice.

# TTL -- One of the following three is optional. The framework looks
# for them in this order. Ignored for Atom feeds.

def ttl(self, obj):
    """
    Takes the object returned by get_object() and returns the feed's
    TTL (Time To Live) as a normal Python string.
    """

def ttl(self):
    """
    Returns the feed's TTL as a normal Python string.
    """

ttl = 600 # Hard-coded Time To Live.

# ITEMS -- One of the following three is required. The framework looks
# for them in this order.

def items(self, obj):
    """
    Takes the object returned by get_object() and returns a list of
    items to publish in this feed.
    """

def items(self):
    """
    Returns a list of items to publish in this feed.
    """

items = ('Item 1', 'Item 2') # Hard-coded items.

# GET_OBJECT -- This is required for feeds that publish different data
# for different URL parameters. (See "A complex example" above.)

def get_object(self, request, *args, **kwargs):
    """
    Takes the current request and the arguments from the URL, and
    returns an object represented by this feed. Raises
```

```

    django.core.exceptions.ObjectDoesNotExist on error.
    """

    # ITEM TITLE AND DESCRIPTION -- If title_template or
    # description_template are not defined, these are used instead. Both are
    # optional, by default they will use the unicode representation of the
    # item.

    def item_title(self, item):
        """
        Takes an item, as returned by items(), and returns the item's
        title as a normal Python string.

        Returns the copyright notice for every item in the feed.
        """

    item_copyright = 'Copyright (c) 2007, Sally Smith' # Hard-coded copyright notice.

```

## The low-level framework

Behind the scenes, the high-level RSS framework uses a lower-level framework for generating feeds' XML. This framework lives in a single module: [django/utils/feedgenerator.py](#).

You use this framework on your own, for lower-level feed generation. You can also create custom feed generator subclasses for use with the `feed_type` Feed option.

## SyndicationFeed classes

The `feedgenerator` module contains a base class:

- `django.utils.feedgenerator.SyndicationFeed`

and several subclasses:

- `django.utils.feedgenerator.RssUserland091Feed`
- `django.utils.feedgenerator.Rss201rev2Feed`
- `django.utils.feedgenerator.Atom1Feed`

Each of these three classes knows how to render a certain type of feed as XML. They share this interface:

**`SyndicationFeed.__init__()`** Initialize the feed with the given dictionary of metadata, which applies to the entire feed. Required keyword arguments are:

- `title`
- `link`
- `description`

There's also a bunch of other optional keywords:

- `language`
- `author_email`
- `author_name`
- `author_link`
- `subtitle`
- `categories`
- `feed_url`
- `feed_copyright`
- `feed_guid`
- `ttl`

Any extra keyword arguments you pass to `__init__` will be stored in `self.feed` for use with *custom feed generators*.

All parameters should be Unicode objects, except `categories`, which should be a sequence of Unicode objects. Beware that some control characters are **not allowed** in XML documents. If your content has some of them, you might encounter a `ValueError` when producing the feed.

**`SyndicationFeed.add_item()`** Add an item to the feed with the given parameters.

Required keyword arguments are:

- `title`
- `link`
- `description`

Optional keyword arguments are:

- `author_email`
- `author_name`
- `author_link`
- `pubdate`

- comments
- unique\_id
- enclosure
- enclosures
- categories
- item\_copyright
- ttl
- updateddate

Extra keyword arguments will be stored for *custom feed generators*.

All parameters, if given, should be Unicode objects, except:

- pubdate should be a Python `datetime` object.
- updateddate should be a Python `datetime` object.
- enclosure should be an instance of `django.utils.feedgenerator.Enclosure`.
- enclosures should be a list of `django.utils.feedgenerator.Enclosure` instances.
- categories should be a sequence of Unicode objects.

Deprecated since version 1.9: The `enclosure` keyword argument is deprecated in favor of the `enclosures` keyword argument.

**`SyndicationFeed.write()`** Outputs the feed in the given encoding to outfile, which is a file-like object.

**`SyndicationFeed.writeString()`** Returns the feed as a string in the given encoding.

For example, to create an Atom 1.0 feed and print it to standard output:

```
>>> from django.utils import feedgenerator
>>> from datetime import datetime
>>> f = feedgenerator.Atom1Feed(
...     title="My Weblog",
...     link="https://www.example.com/",
...     description="In which I write about what I ate today.",
...     language="en",
...     author_name="Myself",
...     feed_url="https://example.com/atom.xml")
>>> f.add_item(title="Hot dog today",
...             link="https://www.example.com/entries/1/",
...             pubdate=datetime.now(),
...             description="<p>Today I had a Vienna Beef hot dog. It was pink, plump and_
↳perfect.</p>")
>>> print(f.writeString('UTF-8'))
<?xml version="1.0" encoding="UTF-8"?>
<feed xmlns="http://www.w3.org/2005/Atom" xml:lang="en">
...
</feed>
```

## Custom feed generators

If you need to produce a custom feed format, you've got a couple of options.

If the feed format is totally custom, you'll want to subclass `SyndicationFeed` and completely replace the `write()` and `writeString()` methods.

However, if the feed format is a spin-off of RSS or Atom (i.e. [GeoRSS](#), Apple's [iTunes podcast format](#), etc.), you've got a better choice. These types of feeds typically add extra elements and/or attributes to the underlying format, and there are a set of methods that `SyndicationFeed` calls to get these extra attributes. Thus, you can subclass the appropriate feed generator class (`Atom1Feed` or `Rss201rev2Feed`) and extend these callbacks. They are:

**`SyndicationFeed.root_attributes(self, )`** Return a dict of attributes to add to the root feed element (`feed/channel`).

**`SyndicationFeed.add_root_elements(self, handler)`** Callback to add elements inside the root feed element (`feed/channel`). `handler` is an `XMLGenerator` from Python's built-in SAX library; you'll call methods on it to add to the XML document in process.

**`SyndicationFeed.item_attributes(self, item)`** Return a dict of attributes to add to each item (`item/entry`) element. The argument, `item`, is a dictionary of all the data passed to `SyndicationFeed.add_item()`.

**`SyndicationFeed.add_item_elements(self, handler, item)`** Callback to add elements to each item (`item/entry`) element. `handler` and `item` are as above.

**Warning:** If you override any of these methods, be sure to call the superclass methods since they add the required elements for each feed format.

For example, you might start implementing an iTunes RSS feed generator like so:

```
class iTunesFeed(Rss201rev2Feed):
    def root_attributes(self):
        attrs = super(iTunesFeed, self).root_attributes()
        attrs['xmlns:itunes'] = 'http://www.itunes.com/dtds/podcast-1.0.dtd'
        return attrs

    def add_root_elements(self, handler):
        super(iTunesFeed, self).add_root_elements(handler)
        handler.addQuickElement('itunes:explicit', 'clean')
```

Obviously there's a lot more work to be done for a complete custom feed class, but the above example should demonstrate the basic idea.

## 6.5.14 admin

The automatic Django administrative interface. For more information, see [Tutorial 2](#) and the [admin documentation](#). Requires the [auth](#) and [contenttypes](#) contrib packages to be installed.

## 6.5.15 auth

Django's authentication framework. See [User authentication in Django](#).

## 6.5.16 contenttypes

A light framework for hooking into "types" of content, where each installed Django model is a separate content type.

See the *contenttypes documentation*.

### 6.5.17 flatpages

A framework for managing simple “flat” HTML content in a database.

See the *flatpages documentation*.

Requires the *sites* contrib package to be installed as well.

### 6.5.18 gis

A world-class geospatial framework built on top of Django, that enables storage, manipulation and display of spatial data.

See the *GeoDjango* documentation for more.

### 6.5.19 humanize

A set of Django template filters useful for adding a “human touch” to data.

See the *humanize documentation*.

### 6.5.20 messages

A framework for storing and retrieving temporary cookie- or session-based messages

See the *messages documentation*.

### 6.5.21 postgres

A collection of PostgreSQL specific features.

See the *contrib.postgres documentation*.

### 6.5.22 redirects

A framework for managing redirects.

See the *redirects documentation*.

### 6.5.23 sessions

A framework for storing data in anonymous sessions.

See the *sessions documentation*.

### 6.5.24 sites

A light framework that lets you operate multiple websites off of the same database and Django installation. It gives you hooks for associating objects to one or more sites.

See the *sites documentation*.

### 6.5.25 sitemaps

A framework for generating Google sitemap XML files.

See the *sitemaps documentation*.

### 6.5.26 syndication

A framework for generating syndication feeds, in RSS and Atom, quite easily.

See the *syndication documentation*.

### 6.5.27 Other add-ons

If you have an idea for functionality to include in `contrib`, let us know! Code it up, and post it to the *django-users* mailing list.

## 6.6 Cross Site Request Forgery protection

The CSRF middleware and template tag provides easy-to-use protection against [Cross Site Request Forgeries](#). This type of attack occurs when a malicious website contains a link, a form button or some JavaScript that is intended to perform some action on your website, using the credentials of a logged-in user who visits the malicious site in their browser. A related type of attack, ‘login CSRF’, where an attacking site tricks a user’s browser into logging into a site with someone else’s credentials, is also covered.

The first defense against CSRF attacks is to ensure that GET requests (and other ‘safe’ methods, as defined by [RFC 7231#section-4.2.1](#)) are side effect free. Requests via ‘unsafe’ methods, such as POST, PUT, and DELETE, can then be protected by following the steps below.

### 6.6.1 How to use it

To take advantage of CSRF protection in your views, follow these steps:

1. The CSRF middleware is activated by default in the `MIDDLEWARE` setting. If you override that setting, remember that `'django.middleware.csrf.CsrfViewMiddleware'` should come before any view middleware that assume that CSRF attacks have been dealt with.

If you disabled it, which is not recommended, you can use `csrf_protect()` on particular views you want to protect (see below).

2. In any template that uses a POST form, use the `csrf_token` tag inside the `<form>` element if the form is for an internal URL, e.g.:

```
<form action="" method="post">{% csrf_token %}
```

This should not be done for POST forms that target external URLs, since that would cause the CSRF token to be leaked, leading to a vulnerability.

3. In the corresponding view functions, ensure that `RequestContext` is used to render the response so that `{% csrf_token %}` will work properly. If you're using the `render()` function, generic views, or contrib apps, you are covered already since these all use `RequestContext`.

## AJAX

While the above method can be used for AJAX POST requests, it has some inconveniences: you have to remember to pass the CSRF token in as POST data with every POST request. For this reason, there is an alternative method: on each `XMLHttpRequest`, set a custom `X-CSRFToken` header to the value of the CSRF token. This is often easier, because many JavaScript frameworks provide hooks that allow headers to be set on every request.

As a first step, you must get the CSRF token itself. The recommended source for the token is the `csrftoken` cookie, which will be set if you've enabled CSRF protection for your views as outlined above.

---

**Note:** The CSRF token cookie is named `csrftoken` by default, but you can control the cookie name via the `CSRF_COOKIE_NAME` setting.

The CSRF header name is `HTTP_X_CSRFTOKEN` by default, but you can customize it using the `CSRF_HEADER_NAME` setting.

---

Acquiring the token is straightforward:

```
// using jQuery
function getCookie(name) {
    var cookieValue = null;
    if (document.cookie && document.cookie !== '') {
        var cookies = document.cookie.split(';');
        for (var i = 0; i < cookies.length; i++) {
            var cookie = jQuery.trim(cookies[i]);
            // Does this cookie string begin with the name we want?
            if (cookie.substring(0, name.length + 1) === (name + '=')) {
                cookieValue = decodeURIComponent(cookie.substring(name.length + 1));
                break;
            }
        }
    }
    return cookieValue;
}
var csrftoken = getCookie('csrftoken');
```

The above code could be simplified by using the [JavaScript Cookie library](#) to replace `getCookie`:

```
var csrftoken = Cookies.get('csrftoken');
```

---

**Note:** The CSRF token is also present in the DOM, but only if explicitly included using `csrf_token` in a template. The cookie contains the canonical token; the `CsrfViewMiddleware` will prefer the cookie to the token in the DOM. Regardless, you're guaranteed to have the cookie if the token is present in the DOM, so you should use the cookie!

---

**Warning:** If your view is not rendering a template containing the `csrf_token` template tag, Django might not set the CSRF token cookie. This is common in cases where forms are dynamically added to the page. To address this case, Django provides a view decorator which forces setting of the cookie: `ensure_csrf_cookie()`.

Finally, you'll have to actually set the header on your AJAX request, while protecting the CSRF token from being sent to other domains using `settings.crossDomain` in jQuery 1.5.1 and newer:

```
function csrfSafeMethod(method) {
    // these HTTP methods do not require CSRF protection
    return (/^(GET|HEAD|OPTIONS|TRACE)$/).test(method);
}
$.ajaxSetup({
    beforeSend: function(xhr, settings) {
        if (!csrfSafeMethod(settings.type) && !this.crossDomain) {
            xhr.setRequestHeader("X-CSRFToken", csrftoken);
        }
    }
});
```

If you're using AngularJS 1.1.3 and newer, it's sufficient to configure the `$http` provider with the cookie and header names:

```
$httpProvider.defaults.xsrfCookieName = 'csrftoken';
$httpProvider.defaults.xsrfHeaderName = 'X-CSRFToken';
```

## Using CSRF in Jinja2 templates

Django's `Jinja2` template backend adds `{{ csrf_input }}` to the context of all templates which is equivalent to `{% csrf_token %}` in the Django template language. For example:

```
<form action="" method="post">{{ csrf_input }}
```

## The decorator method

Rather than adding `CsrfViewMiddleware` as a blanket protection, you can use the `csrf_protect` decorator, which has exactly the same functionality, on particular views that need the protection. It must be used **both** on views that insert the CSRF token in the output, and on those that accept the POST form data. (These are often the same view function, but not always).

Use of the decorator by itself is **not recommended**, since if you forget to use it, you will have a security hole. The 'belt and braces' strategy of using both is fine, and will incur minimal overhead.

### `csrf_protect` (*view*)

Decorator that provides the protection of `CsrfViewMiddleware` to a view.

Usage:

```
from django.views.decorators.csrf import csrf_protect
from django.shortcuts import render

@csrf_protect
def my_view(request):
    c = {}
```

```
# ...
return render(request, "a_template.html", c)
```

If you are using class-based views, you can refer to *Decorating class-based views*.

## 6.6.2 Rejected requests

By default, a ‘403 Forbidden’ response is sent to the user if an incoming request fails the checks performed by `CsrfViewMiddleware`. This should usually only be seen when there is a genuine Cross Site Request Forgery, or when, due to a programming error, the CSRF token has not been included with a POST form.

The error page, however, is not very friendly, so you may want to provide your own view for handling this condition. To do this, simply set the `CSRF_FAILURE_VIEW` setting.

CSRF failures are logged as warnings to the `django.request` logger.

## 6.6.3 How it works

The CSRF protection is based on the following things:

1. A CSRF cookie that is based on a random secret value, which other sites will not have access to.

This cookie is set by `CsrfViewMiddleware`. It is sent with every response that has called `django.middleware.csrf.get_token()` (the function used internally to retrieve the CSRF token), if it wasn’t already set on the request.

In order to protect against **BREACH** attacks, the token is not simply the secret; a random salt is prepended to the secret and used to scramble it.

For security reasons, the value of the secret is changed each time a user logs in.

2. A hidden form field with the name ‘`csrfmiddlewaretoken`’ present in all outgoing POST forms. The value of this field is, again, the value of the secret, with a salt which is both added to it and used to scramble it. The salt is regenerated on every call to `get_token()` so that the form field value is changed in every such response.

This part is done by the template tag.

3. For all incoming requests that are not using HTTP GET, HEAD, OPTIONS or TRACE, a CSRF cookie must be present, and the ‘`csrfmiddlewaretoken`’ field must be present and correct. If it isn’t, the user will get a 403 error.

When validating the ‘`csrfmiddlewaretoken`’ field value, only the secret, not the full token, is compared with the secret in the cookie value. This allows the use of ever-changing tokens. While each request may use its own token, the secret remains common to all.

This check is done by `CsrfViewMiddleware`.

4. In addition, for HTTPS requests, strict referer checking is done by `CsrfViewMiddleware`. This means that even if a subdomain can set or modify cookies on your domain, it can’t force a user to post to your application since that request won’t come from your own exact domain.

This also addresses a man-in-the-middle attack that’s possible under HTTPS when using a session independent secret, due to the fact that HTTP `Set-Cookie` headers are (unfortunately) accepted by clients even when they are talking to a site under HTTPS. (Referer checking is not done for HTTP requests because the presence of the `Referer` header isn’t reliable enough under HTTP.)

If the `CSRF_COOKIE_DOMAIN` setting is set, the referer is compared against it. This setting supports subdomains. For example, `CSRF_COOKIE_DOMAIN = '.example.com'` will allow POST requests from `www.example.com` and `api.example.com`. If the setting is not set, then the referer must match the HTTP `Host` header.

Expanding the accepted referers beyond the current host or cookie domain can be done with the `CSRF_TRUSTED_ORIGINS` setting.

This ensures that only forms that have originated from trusted domains can be used to POST data back.

It deliberately ignores GET requests (and other requests that are defined as ‘safe’ by [RFC 7231](#)). These requests ought never to have any potentially dangerous side effects, and so a CSRF attack with a GET request ought to be harmless. [RFC 7231](#) defines POST, PUT, and DELETE as ‘unsafe’, and all other methods are also assumed to be unsafe, for maximum protection.

The CSRF protection cannot protect against man-in-the-middle attacks, so use [HTTPS](#) with [HTTP Strict Transport Security](#). It also assumes *validation of the HOST header* and that there aren’t any *cross-site scripting vulnerabilities* on your site (because XSS vulnerabilities already let an attacker do anything a CSRF vulnerability allows and much worse).

Checking against the `CSRF_COOKIE_DOMAIN` setting was added.

Added salting to the token and started changing it with each request to protect against [BREACH](#) attacks.

## 6.6.4 Caching

If the `csrf_token` template tag is used by a template (or the `get_token` function is called some other way), `CsrfViewMiddleware` will add a cookie and a `Vary: Cookie` header to the response. This means that the middleware will play well with the cache middleware if it is used as instructed (`UpdateCacheMiddleware` goes before all other middleware).

However, if you use cache decorators on individual views, the CSRF middleware will not yet have been able to set the Vary header or the CSRF cookie, and the response will be cached without either one. In this case, on any views that will require a CSRF token to be inserted you should use the `django.views.decorators.csrf.csrf_protect()` decorator first:

```
from django.views.decorators.cache import cache_page
from django.views.decorators.csrf import csrf_protect

@cache_page(60 * 15)
@csrf_protect
def my_view(request):
    ...
```

If you are using class-based views, you can refer to [Decorating class-based views](#).

## 6.6.5 Testing

The `CsrfViewMiddleware` will usually be a big hindrance to testing view functions, due to the need for the CSRF token which must be sent with every POST request. For this reason, Django’s HTTP client for tests has been modified to set a flag on requests which relaxes the middleware and the `csrf_protect` decorator so that they no longer rejects requests. In every other respect (e.g. sending cookies etc.), they behave the same.

If, for some reason, you *want* the test client to perform CSRF checks, you can create an instance of the test client that enforces CSRF checks:

```
>>> from django.test import Client
>>> csrf_client = Client(enforce_csrf_checks=True)
```

## 6.6.6 Limitations

Subdomains within a site will be able to set cookies on the client for the whole domain. By setting the cookie and using a corresponding token, subdomains will be able to circumvent the CSRF protection. The only way to avoid this is to ensure that subdomains are controlled by trusted users (or, are at least unable to set cookies). Note that even without CSRF, there are other vulnerabilities, such as session fixation, that make giving subdomains to untrusted parties a bad idea, and these vulnerabilities cannot easily be fixed with current browsers.

## 6.6.7 Edge cases

Certain views can have unusual requirements that mean they don't fit the normal pattern envisaged here. A number of utilities can be useful in these situations. The scenarios they might be needed in are described in the following section.

### Utilities

The examples below assume you are using function-based views. If you are working with class-based views, you can refer to *Decorating class-based views*.

#### `csrf_exempt` (*view*)

This decorator marks a view as being exempt from the protection ensured by the middleware. Example:

```
from django.views.decorators.csrf import csrf_exempt
from django.http import HttpResponse

@csrf_exempt
def my_view(request):
    return HttpResponse('Hello world')
```

#### `requires_csrf_token` (*view*)

Normally the `csrf_token` template tag will not work if `CsrfViewMiddleware.process_view` or an equivalent like `csrf_protect` has not run. The view decorator `requires_csrf_token` can be used to ensure the template tag does work. This decorator works similarly to `csrf_protect`, but never rejects an incoming request.

Example:

```
from django.views.decorators.csrf import requires_csrf_token
from django.shortcuts import render

@requires_csrf_token
def my_view(request):
    c = {}
    # ...
    return render(request, "a_template.html", c)
```

#### `ensure_csrf_cookie` (*view*)

This decorator forces a view to send the CSRF cookie.

### Scenarios

#### CSRF protection should be disabled for just a few views

Most views requires CSRF protection, but a few do not.

Solution: rather than disabling the middleware and applying `csrf_protect` to all the views that need it, enable the middleware and use `csrf_exempt()`.

### CsrfViewMiddleware.process\_view not used

There are cases when `CsrfViewMiddleware.process_view` may not have run before your view is run - 404 and 500 handlers, for example - but you still need the CSRF token in a form.

Solution: use `requires_csrf_token()`

### Unprotected view needs the CSRF token

There may be some views that are unprotected and have been exempted by `csrf_exempt`, but still need to include the CSRF token.

Solution: use `csrf_exempt()` followed by `requires_csrf_token()`. (i.e. `requires_csrf_token` should be the innermost decorator).

### View needs protection for one path

A view needs CSRF protection under one set of conditions only, and mustn't have it for the rest of the time.

Solution: use `csrf_exempt()` for the whole view function, and `csrf_protect()` for the path within it that needs protection. Example:

```
from django.views.decorators.csrf import csrf_exempt, csrf_protect

@csrf_exempt
def my_view(request):

    @csrf_protect
    def protected_path(request):
        do_something()

    if some_condition():
        return protected_path(request)
    else:
        do_something_else()
```

### Page uses AJAX without any HTML form

A page makes a POST request via AJAX, and the page does not have an HTML form with a `csrf_token` that would cause the required CSRF cookie to be sent.

Solution: use `ensure_csrf_cookie()` on the view that sends the page.

## 6.6.8 Contrib and reusable apps

Because it is possible for the developer to turn off the `CsrfViewMiddleware`, all relevant views in contrib apps use the `csrf_protect` decorator to ensure the security of these applications against CSRF. It is recommended that the developers of other reusable apps that want the same guarantees also use the `csrf_protect` decorator on their views.

## 6.6.9 Settings

A number of settings can be used to control Django’s CSRF behavior:

- `CSRF_COOKIE_AGE`
- `CSRF_COOKIE_DOMAIN`
- `CSRF_COOKIE_HTTPONLY`
- `CSRF_COOKIE_NAME`
- `CSRF_COOKIE_PATH`
- `CSRF_COOKIE_SECURE`
- `CSRF_FAILURE_VIEW`
- `CSRF_HEADER_NAME`
- `CSRF_TRUSTED_ORIGINS`

## 6.6.10 Frequently Asked Questions

### Is posting an arbitrary CSRF token pair (cookie and POST data) a vulnerability?

No, this is by design. Without a man-in-the-middle attack, there is no way for an attacker to send a CSRF token cookie to a victim’s browser, so a successful attack would need to obtain the victim’s browser’s cookie via XSS or similar, in which case an attacker usually doesn’t need CSRF attacks.

Some security audit tools flag this as a problem but as mentioned before, an attacker cannot steal a user’s browser’s CSRF cookie. “Stealing” or modifying *your own* token using Firebug, Chrome dev tools, etc. isn’t a vulnerability.

### Is the fact that Django’s CSRF protection isn’t linked to a session a problem?

No, this is by design. Not linking CSRF protection to a session allows using the protection on sites such as a *pastebin* that allow submissions from anonymous users which don’t have a session.

### Why might a user encounter a CSRF validation failure after logging in?

For security reasons, CSRF tokens are rotated each time a user logs in. Any page with a form generated before a login will have an old, invalid CSRF token and need to be reloaded. This might happen if a user uses the back button after a login or if they log in in a different browser tab.

## 6.7 Databases

Django attempts to support as many features as possible on all database backends. However, not all database backends are alike, and we’ve had to make design decisions on which features to support and which assumptions we can make safely.

This file describes some of the features that might be relevant to Django usage. Of course, it is not intended as a replacement for server-specific documentation or reference manuals.

## 6.7.1 General notes

### Persistent connections

Persistent connections avoid the overhead of re-establishing a connection to the database in each request. They're controlled by the `CONN_MAX_AGE` parameter which defines the maximum lifetime of a connection. It can be set independently for each database.

The default value is 0, preserving the historical behavior of closing the database connection at the end of each request. To enable persistent connections, set `CONN_MAX_AGE` to a positive number of seconds. For unlimited persistent connections, set it to `None`.

### Connection management

Django opens a connection to the database when it first makes a database query. It keeps this connection open and reuses it in subsequent requests. Django closes the connection once it exceeds the maximum age defined by `CONN_MAX_AGE` or when it isn't usable any longer.

In detail, Django automatically opens a connection to the database whenever it needs one and doesn't have one already — either because this is the first connection, or because the previous connection was closed.

At the beginning of each request, Django closes the connection if it has reached its maximum age. If your database terminates idle connections after some time, you should set `CONN_MAX_AGE` to a lower value, so that Django doesn't attempt to use a connection that has been terminated by the database server. (This problem may only affect very low traffic sites.)

At the end of each request, Django closes the connection if it has reached its maximum age or if it is in an unrecoverable error state. If any database errors have occurred while processing the requests, Django checks whether the connection still works, and closes it if it doesn't. Thus, database errors affect at most one request; if the connection becomes unusable, the next request gets a fresh connection.

### Caveats

Since each thread maintains its own connection, your database must support at least as many simultaneous connections as you have worker threads.

Sometimes a database won't be accessed by the majority of your views, for example because it's the database of an external system, or thanks to caching. In such cases, you should set `CONN_MAX_AGE` to a low value or even 0, because it doesn't make sense to maintain a connection that's unlikely to be reused. This will help keep the number of simultaneous connections to this database small.

The development server creates a new thread for each request it handles, negating the effect of persistent connections. Don't enable them during development.

When Django establishes a connection to the database, it sets up appropriate parameters, depending on the backend being used. If you enable persistent connections, this setup is no longer repeated every request. If you modify parameters such as the connection's isolation level or time zone, you should either restore Django's defaults at the end of each request, force an appropriate value at the beginning of each request, or disable persistent connections.

### Encoding

Django assumes that all databases use UTF-8 encoding. Using other encodings may result in unexpected behavior such as "value too long" errors from your database for data that is valid in Django. See the database specific notes below for information on how to set up your database correctly.

## 6.7.2 PostgreSQL notes

Django supports PostgreSQL 9.2 and higher. It requires the use of `psycopg2` 2.4.5 or higher (or 2.5+ if you want to use `django.contrib.postgres`).

### PostgreSQL connection settings

See `HOST` for details.

### Optimizing PostgreSQL's configuration

Django needs the following parameters for its database connections:

- `client_encoding`: 'UTF8',
- `default_transaction_isolation`: 'read committed' by default, or the value set in the connection options (see below),
- `timezone`: 'UTC' when `USE_TZ` is True, value of `TIME_ZONE` otherwise.

If these parameters already have the correct values, Django won't set them for every new connection, which improves performance slightly. You can configure them directly in `postgresql.conf` or more conveniently per database user with `ALTER ROLE`.

Django will work just fine without this optimization, but each new connection will do some additional queries to set these parameters.

### Isolation level

Like PostgreSQL itself, Django defaults to the `READ COMMITTED` isolation level. If you need a higher isolation level such as `REPEATABLE READ` or `SERIALIZABLE`, set it in the `OPTIONS` part of your database configuration in `DATABASES`:

```
import psycopg2.extensions

DATABASES = {
    # ...
    'OPTIONS': {
        'isolation_level': psycopg2.extensions.ISOLATION_LEVEL_SERIALIZABLE,
    },
}
```

---

**Note:** Under higher isolation levels, your application should be prepared to handle exceptions raised on serialization failures. This option is designed for advanced uses.

---

### Indexes for varchar and text columns

When specifying `db_index=True` on your model fields, Django typically outputs a single `CREATE INDEX` statement. However, if the database type for the field is either `varchar` or `text` (e.g., used by `CharField`, `FileField`, and `TextField`), then Django will create an additional index that uses an appropriate PostgreSQL operator class for the column. The extra index is necessary to correctly perform lookups that use the `LIKE` operator in their SQL, as is done with the `contains` and `startswith` lookup types.

## Migration operation for adding extensions

If you need to add a PostgreSQL extension (like `hstore`, `postgis`, etc.) using a migration, use the `CreateExtension` operation.

## Speeding up test execution with non-durable settings

You can speed up test execution times by [configuring PostgreSQL to be non-durable](#).

**Warning:** This is dangerous: it will make your database more susceptible to data loss or corruption in the case of a server crash or power loss. Only use this on a development machine where you can easily restore the entire contents of all databases in the cluster.

## 6.7.3 MySQL notes

### Version support

Django supports MySQL 5.5 and higher.

Django’s `inspectdb` feature uses the `information_schema` database, which contains detailed data on all database schemas.

Django expects the database to support Unicode (UTF-8 encoding) and delegates to it the task of enforcing transactions and referential integrity. It is important to be aware of the fact that the two latter ones aren’t actually enforced by MySQL when using the MyISAM storage engine, see the next section.

### Storage engines

MySQL has several [storage engines](#). You can change the default storage engine in the server configuration.

Until MySQL 5.5.4, the default engine was [MyISAM](#)<sup>1</sup>. The main drawbacks of MyISAM are that it doesn’t support transactions or enforce foreign-key constraints. On the plus side, it was the only engine that supported full-text indexing and searching until MySQL 5.6.4.

Since MySQL 5.5.5, the default storage engine is [InnoDB](#). This engine is fully transactional and supports foreign key references. It’s probably the best choice at this point. However, note that the InnoDB autoincrement counter is lost on a MySQL restart because it does not remember the `AUTO_INCREMENT` value, instead recreating it as “`max(id)+1`”. This may result in an inadvertent reuse of `AutoField` values.

If you upgrade an existing project to MySQL 5.5.5 and subsequently add some tables, ensure that your tables are using the same storage engine (i.e. MyISAM vs. InnoDB). Specifically, if tables that have a `ForeignKey` between them use different storage engines, you may see an error like the following when running `migrate`:

```
_mysql_exceptions.OperationalError: (
  1005, "Can't create table '\\db_name\\.#sql-4a8_ab' (errno: 150)"
)
```

---

<sup>1</sup> Unless this was changed by the packager of your MySQL package. We’ve had reports that the Windows Community Server installer sets up InnoDB as the default storage engine, for example.

## MySQL DB API Drivers

The Python Database API is described in [PEP 249](#). MySQL has three prominent drivers that implement this API:

- [MySQLdb](#) is a native driver that has been developed and supported for over a decade by Andy Dustman.
- [mysqlclient](#) is a fork of `MySQLdb` which notably supports Python 3 and can be used as a drop-in replacement for `MySQLdb`. At the time of this writing, this is **the recommended choice** for using MySQL with Django.
- [MySQL Connector/Python](#) is a pure Python driver from Oracle that does not require the MySQL client library or any Python modules outside the standard library.

All these drivers are thread-safe and provide connection pooling. `MySQLdb` is the only one not supporting Python 3 currently.

In addition to a DB API driver, Django needs an adapter to access the database drivers from its ORM. Django provides an adapter for `MySQLdb`/`mysqlclient` while `MySQL Connector/Python` includes [its own](#).

## MySQLdb

Django requires `MySQLdb` version 1.2.1p2 or later.

At the time of writing, the latest release of `MySQLdb` (1.2.5) doesn't support Python 3. In order to use `MySQLdb` under Python 3, you'll have to install `mysqlclient` instead.

---

**Note:** There are known issues with the way `MySQLdb` converts date strings into datetime objects. Specifically, date strings with value `0000-00-00` are valid for MySQL but will be converted into `None` by `MySQLdb`.

This means you should be careful while using `loaddata` and `dumpdata` with rows that may have `0000-00-00` values, as they will be converted to `None`.

---

## mysqlclient

Django requires `mysqlclient` 1.3.3 or later. Note that Python 3.2 is not supported. Except for the Python 3.3+ support, `mysqlclient` should mostly behave the same as `MySQLDB`.

## MySQL Connector/Python

`MySQL Connector/Python` is available from the [download page](#). The Django adapter is available in versions 1.1.X and later. It may not support the most recent releases of Django.

## Time zone definitions

If you plan on using Django's [timezone support](#), use `mysql_tzinfo_to_sql` to load time zone tables into the MySQL database. This needs to be done just once for your MySQL server, not per database.

## Creating your database

You can [create your database](#) using the command-line tools and this SQL:

```
CREATE DATABASE <dbname> CHARACTER SET utf8;
```

This ensures all tables and columns will use UTF-8 by default.

## Collation settings

The collation setting for a column controls the order in which data is sorted as well as what strings compare as equal. It can be set on a database-wide level and also per-table and per-column. This is [documented thoroughly](#) in the MySQL documentation. In all cases, you set the collation by directly manipulating the database tables; Django doesn't provide a way to set this on the model definition.

By default, with a UTF-8 database, MySQL will use the `utf8_general_ci` collation. This results in all string equality comparisons being done in a *case-insensitive* manner. That is, "Fred" and "freD" are considered equal at the database level. If you have a unique constraint on a field, it would be illegal to try to insert both "aa" and "AA" into the same column, since they compare as equal (and, hence, non-unique) with the default collation.

In many cases, this default will not be a problem. However, if you really want case-sensitive comparisons on a particular column or table, you would change the column or table to use the `utf8_bin` collation. The main thing to be aware of in this case is that if you are using MySQLdb 1.2.2, the database backend in Django will then return bytestrings (instead of unicode strings) for any character fields it receive from the database. This is a strong variation from Django's normal practice of *always* returning unicode strings. It is up to you, the developer, to handle the fact that you will receive bytestrings if you configure your table(s) to use `utf8_bin` collation. Django itself should mostly work smoothly with such columns (except for the `contrib.sessions.Session` and `contrib.admin.LogEntry` tables described below), but your code must be prepared to call `django.utils.encoding.smart_text()` at times if it really wants to work with consistent data – Django will not do this for you (the database backend layer and the model population layer are separated internally so the database layer doesn't know it needs to make this conversion in this one particular case).

If you're using MySQLdb 1.2.1p2, Django's standard `CharField` class will return unicode strings even with `utf8_bin` collation. However, `TextField` fields will be returned as an `array.array` instance (from Python's standard `array` module). There isn't a lot Django can do about that, since, again, the information needed to make the necessary conversions isn't available when the data is read in from the database. This problem was [fixed in MySQLdb 1.2.2](#), so if you want to use `TextField` with `utf8_bin` collation, upgrading to version 1.2.2 and then dealing with the bytestrings (which shouldn't be too difficult) as described above is the recommended solution.

Should you decide to use `utf8_bin` collation for some of your tables with MySQLdb 1.2.1p2 or 1.2.2, you should still use `utf8_general_ci` (the default) collation for the `django.contrib.sessions.models.Session` table (usually called `django_session`) and the `django.contrib.admin.models.LogEntry` table (usually called `django_admin_log`). Those are the two standard tables that use `TextField` internally.

Please note that according to [MySQL Unicode Character Sets](#), comparisons for the `utf8_general_ci` collation are faster, but slightly less correct, than comparisons for `utf8_unicode_ci`. If this is acceptable for your application, you should use `utf8_general_ci` because it is faster. If this is not acceptable (for example, if you require German dictionary order), use `utf8_unicode_ci` because it is more accurate.

**Warning:** Model formsets validate unique fields in a case-sensitive manner. Thus when using a case-insensitive collation, a formset with unique field values that differ only by case will pass validation, but upon calling `save()`, an `IntegrityError` will be raised.

## Connecting to the database

Refer to the [settings documentation](#).

Connection settings are used in this order:

1. `OPTIONS`.

2. *NAME*, *USER*, *PASSWORD*, *HOST*, *PORT*

3. MySQL option files.

In other words, if you set the name of the database in *OPTIONS*, this will take precedence over *NAME*, which would override anything in a [MySQL option file](#).

Here's a sample configuration which uses a MySQL option file:

```
# settings.py
DATABASES = {
    'default': {
        'ENGINE': 'django.db.backends.mysql',
        'OPTIONS': {
            'read_default_file': '/path/to/my.cnf',
        },
    }
}

# my.cnf
[client]
database = NAME
user = USER
password = PASSWORD
default-character-set = utf8
```

Several other MySQLdb connection options may be useful, such as `ssl`, `init_command`, and `sql_mode`. Consult the [MySQLdb documentation](#) for more details.

### Setting `sql_mode`

From MySQL 5.7 onwards and on fresh installs of MySQL 5.6, the default value of the `sql_mode` option contains `STRICT_TRANS_TABLES`. That option escalates warnings into errors when data are truncated upon insertion, so Django highly recommends activating a [strict mode](#) for MySQL to prevent data loss (either `STRICT_TRANS_TABLES` or `STRICT_ALL_TABLES`).

If you need to customize the SQL mode, you can set the `sql_mode` variable like other MySQL options: either in a config file or with the entry `'init_command': "SET sql_mode='STRICT_TRANS_TABLES'"` in the *OPTIONS* part of your database configuration in *DATABASES*.

### Creating your tables

When Django generates the schema, it doesn't specify a storage engine, so tables will be created with whatever default storage engine your database server is configured for. The easiest solution is to set your database server's default storage engine to the desired engine.

If you're using a hosting service and can't change your server's default storage engine, you have a couple of options.

- After the tables are created, execute an `ALTER TABLE` statement to convert a table to a new storage engine (such as InnoDB):

```
ALTER TABLE <tablename> ENGINE=INNODB;
```

This can be tedious if you have a lot of tables.

- Another option is to use the `init_command` option for MySQLdb prior to creating your tables:

```
'OPTIONS': {
    'init_command': 'SET default_storage_engine=INNODB',
}
```

This sets the default storage engine upon connecting to the database. After your tables have been created, you should remove this option as it adds a query that is only needed during table creation to each database connection.

## Table names

There are [known issues](#) in even the latest versions of MySQL that can cause the case of a table name to be altered when certain SQL statements are executed under certain conditions. It is recommended that you use lowercase table names, if possible, to avoid any problems that might arise from this behavior. Django uses lowercase table names when it auto-generates table names from models, so this is mainly a consideration if you are overriding the table name via the `db_table` parameter.

## Savepoints

Both the Django ORM and MySQL (when using the InnoDB *storage engine*) support database *savepoints*.

If you use the MyISAM storage engine please be aware of the fact that you will receive database-generated errors if you try to use the *savepoint-related methods of the transactions API*. The reason for this is that detecting the storage engine of a MySQL database/table is an expensive operation so it was decided it isn't worth to dynamically convert these methods in no-op's based in the results of such detection.

## Notes on specific fields

### Character fields

Any fields that are stored with VARCHAR column types have their `max_length` restricted to 255 characters if you are using `unique=True` for the field. This affects `CharField`, `SlugField` and `CommaSeparatedIntegerField`.

### TextField limitations

MySQL can index only the first N chars of a BLOB or TEXT column. Since `TextField` doesn't have a defined length, you can't mark it as `unique=True`. MySQL will report: "BLOB/TEXT column '<db\_column>' used in key specification without a key length".

## Fractional seconds support for Time and DateTime fields

MySQL 5.6.4 and later can store fractional seconds, provided that the column definition includes a fractional indication (e.g. `DATETIME(6)`). Earlier versions do not support them at all. In addition, versions of MySQLdb older than 1.2.5 have a [bug](#) that also prevents the use of fractional seconds with MySQL.

Django will not upgrade existing columns to include fractional seconds if the database server supports it. If you want to enable them on an existing database, it's up to you to either manually update the column on the target database, by executing a command like:

```
ALTER TABLE `your_table` MODIFY `your_datetime_column` DATETIME(6)
```

or using a `RunSQL` operation in a *data migration*.

### TIMESTAMP columns

If you are using a legacy database that contains `TIMESTAMP` columns, you must set `USE_TZ = False` to avoid data corruption. `inspectdb` maps these columns to `DateTimeField` and if you enable timezone support, both MySQL and Django will attempt to convert the values from UTC to local time.

### Row locking with `QuerySet.select_for_update()`

MySQL does not support the `NOWAIT` option to the `SELECT ... FOR UPDATE` statement. If `select_for_update()` is used with `nowait=True` then a `DatabaseError` will be raised.

### Automatic typecasting can cause unexpected results

When performing a query on a string type, but with an integer value, MySQL will coerce the types of all values in the table to an integer before performing the comparison. If your table contains the values `'abc'`, `'def'` and you query for `WHERE mycolumn=0`, both rows will match. Similarly, `WHERE mycolumn=1` will match the value `'abc1'`. Therefore, string type fields included in Django will always cast the value to a string before using it in a query.

If you implement custom model fields that inherit from `Field` directly, are overriding `get_prep_value()`, or use `RawSQL`, `extra()`, or `raw()`, you should ensure that you perform appropriate typecasting.

## 6.7.4 SQLite notes

SQLite provides an excellent development alternative for applications that are predominantly read-only or require a smaller installation footprint. As with all database servers, though, there are some differences that are specific to SQLite that you should be aware of.

### Substring matching and case sensitivity

For all SQLite versions, there is some slightly counter-intuitive behavior when attempting to match some types of strings. These are triggered when using the `iexact` or `contains` filters in Querysets. The behavior splits into two cases:

1. For substring matching, all matches are done case-insensitively. That is a filter such as `filter(name__contains="aa")` will match a name of `"Aabb"`.
2. For strings containing characters outside the ASCII range, all exact string matches are performed case-sensitively, even when the case-insensitive options are passed into the query. So the `iexact` filter will behave exactly the same as the `exact` filter in these cases.

Some possible workarounds for this are [documented at sqlite.org](http://sqlite.org), but they aren't utilized by the default SQLite backend in Django, as incorporating them would be fairly difficult to do robustly. Thus, Django exposes the default SQLite behavior and you should be aware of this when doing case-insensitive or substring filtering.

## Old SQLite and CASE expressions

SQLite 3.6.23.1 and older contains a bug when handling query parameters in a CASE expression that contains an ELSE and arithmetic.

SQLite 3.6.23.1 was released in March 2010, and most current binary distributions for different platforms include a newer version of SQLite, with the notable exception of the Python 2.7 installers for Windows.

As of this writing, the latest release for Windows - Python 2.7.10 - includes SQLite 3.6.21. You can install `pysqlite2` or replace `sqlite3.dll` (by default installed in `C:\Python27\DLLs`) with a newer version from <https://www.sqlite.org/> to remedy this issue.

## Using newer versions of the SQLite DB-API 2.0 driver

Django will use a `pysqlite2` module in preference to `sqlite3` as shipped with the Python standard library if it finds one is available.

This provides the ability to upgrade both the DB-API 2.0 interface or SQLite 3 itself to versions newer than the ones included with your particular Python binary distribution, if needed.

## “Database is locked” errors

SQLite is meant to be a lightweight database, and thus can’t support a high level of concurrency. `OperationalError: database is locked` errors indicate that your application is experiencing more concurrency than `sqlite` can handle in default configuration. This error means that one thread or process has an exclusive lock on the database connection and another thread timed out waiting for the lock to be released.

Python’s SQLite wrapper has a default timeout value that determines how long the second thread is allowed to wait on the lock before it times out and raises the `OperationalError: database is locked` error.

If you’re getting this error, you can solve it by:

- Switching to another database backend. At a certain point SQLite becomes too “lite” for real-world applications, and these sorts of concurrency errors indicate you’ve reached that point.
- Rewriting your code to reduce concurrency and ensure that database transactions are short-lived.
- Increase the default timeout value by setting the `timeout` database option:

```
'OPTIONS': {
    # ...
    'timeout': 20,
    # ...
}
```

This will simply make SQLite wait a bit longer before throwing “database is locked” errors; it won’t really do anything to solve them.

## `QuerySet.select_for_update()` not supported

SQLite does not support the `SELECT ... FOR UPDATE` syntax. Calling it will have no effect.

## “pyformat” parameter style in raw queries not supported

For most backends, raw queries (`Manager.raw()` or `cursor.execute()`) can use the “pyformat” parameter style, where placeholders in the query are given as `'%(name)s'` and the parameters are passed as a dictionary rather than a list. SQLite does not support this.

### 6.7.5 Oracle notes

Django supports [Oracle Database Server](#) versions 11.2 and higher. Versions 4.3.1 through 5.2.1 of the `cx_Oracle` Python driver are supported, although 5.1.3 or later is recommended as these versions support Python 3.

Note that due to a Unicode-corruption bug in `cx_Oracle` 5.0, that version of the driver should **not** be used with Django; `cx_Oracle` 5.0.1 resolved this issue, so if you'd like to use a more recent `cx_Oracle`, use version 5.0.1.

`cx_Oracle` 5.0.1 or greater can optionally be compiled with the `WITH_UNICODE` environment variable. This is recommended but not required.

In order for the `python manage.py migrate` command to work, your Oracle database user must have privileges to run the following commands:

- CREATE TABLE
- CREATE SEQUENCE
- CREATE PROCEDURE
- CREATE TRIGGER

To run a project's test suite, the user usually needs these *additional* privileges:

- CREATE USER
- ALTER USER
- DROP USER
- CREATE TABLESPACE
- DROP TABLESPACE
- CREATE SESSION WITH ADMIN OPTION
- CREATE TABLE WITH ADMIN OPTION
- CREATE SEQUENCE WITH ADMIN OPTION
- CREATE PROCEDURE WITH ADMIN OPTION
- CREATE TRIGGER WITH ADMIN OPTION

Note that, while the `RESOURCE` role has the required `CREATE TABLE`, `CREATE SEQUENCE`, `CREATE PROCEDURE` and `CREATE TRIGGER` privileges, and a user granted `RESOURCE WITH ADMIN OPTION` can grant `RESOURCE`, such a user cannot grant the individual privileges (e.g. `CREATE TABLE`), and thus `RESOURCE WITH ADMIN OPTION` is not usually sufficient for running tests.

Some test suites also create views; to run these, the user also needs the `CREATE VIEW WITH ADMIN OPTION` privilege. In particular, this is needed for Django's own test suite.

All of these privileges are included in the `DBA` role, which is appropriate for use on a private developer's database.

The Oracle database backend uses the `SYS.DBMS_LOB` and `SYS.DBMS_RANDOM` packages, so your user will require execute permissions on it. It's normally accessible to all users by default, but in case it is not, you'll need to grant permissions like so:

```
GRANT EXECUTE ON SYS.DBMS_LOB TO user;
GRANT EXECUTE ON SYS.DBMS_RANDOM TO user;
```

## Connecting to the database

To connect using the service name of your Oracle database, your `settings.py` file should look something like this:

```
DATABASES = {
    'default': {
        'ENGINE': 'django.db.backends.oracle',
        'NAME': 'xe',
        'USER': 'a_user',
        'PASSWORD': 'a_password',
        'HOST': '',
        'PORT': '',
    }
}
```

In this case, you should leave both `HOST` and `PORT` empty. However, if you don't use a `tnsnames.ora` file or a similar naming method and want to connect using the SID (“xe” in this example), then fill in both `HOST` and `PORT` like so:

```
DATABASES = {
    'default': {
        'ENGINE': 'django.db.backends.oracle',
        'NAME': 'xe',
        'USER': 'a_user',
        'PASSWORD': 'a_password',
        'HOST': 'dbprod01ned.mycompany.com',
        'PORT': '1540',
    }
}
```

You should either supply both `HOST` and `PORT`, or leave both as empty strings. Django will use a different connect descriptor depending on that choice.

## Threaded option

If you plan to run Django in a multithreaded environment (e.g. Apache using the default MPM module on any modern operating system), then you **must** set the `threaded` option of your Oracle database configuration to `True`:

```
'OPTIONS': {
    'threaded': True,
},
```

Failure to do this may result in crashes and other odd behavior.

## INSERT ... RETURNING INTO

By default, the Oracle backend uses a `RETURNING INTO` clause to efficiently retrieve the value of an `AutoField` when inserting new rows. This behavior may result in a `DatabaseError` in certain unusual setups, such as when inserting into a remote table, or into a view with an `INSTEAD OF` trigger. The `RETURNING INTO` clause can be disabled by setting the `use_returning_into` option of the database configuration to `False`:

```
'OPTIONS': {
    'use_returning_into': False,
},
```

In this case, the Oracle backend will use a separate `SELECT` query to retrieve `AutoField` values.

## Naming issues

Oracle imposes a name length limit of 30 characters. To accommodate this, the backend truncates database identifiers to fit, replacing the final four characters of the truncated name with a repeatable MD5 hash value. Additionally, the backend turns database identifiers to all-uppercase.

To prevent these transformations (this is usually required only when dealing with legacy databases or accessing tables which belong to other users), use a quoted name as the value for `db_table`:

```
class LegacyModel(models.Model):
    class Meta:
        db_table = "name_left_in_lowercase"

class ForeignModel(models.Model):
    class Meta:
        db_table = "OTHER_USER"."NAME_ONLY_SEEMS_OVER_30"
```

Quoted names can also be used with Django's other supported database backends; except for Oracle, however, the quotes have no effect.

When running `migrate`, an `ORA-06552` error may be encountered if certain Oracle keywords are used as the name of a model field or the value of a `db_column` option. Django quotes all identifiers used in queries to prevent most such problems, but this error can still occur when an Oracle datatype is used as a column name. In particular, take care to avoid using the names `date`, `timestamp`, `number` or `float` as a field name.

## NULL and empty strings

Django generally prefers to use the empty string (`''`) rather than `NULL`, but Oracle treats both identically. To get around this, the Oracle backend ignores an explicit `null` option on fields that have the empty string as a possible value and generates DDL as if `null=True`. When fetching from the database, it is assumed that a `NULL` value in one of these fields really means the empty string, and the data is silently converted to reflect this assumption.

## TextField limitations

The Oracle backend stores `TextFields` as `NCLOB` columns. Oracle imposes some limitations on the usage of such `LOB` columns in general:

- `LOB` columns may not be used as primary keys.
- `LOB` columns may not be used in indexes.
- `LOB` columns may not be used in a `SELECT DISTINCT` list. This means that attempting to use the `QuerySet.distinct` method on a model that includes `TextField` columns will result in an `ORA-00932` error when run against Oracle. As a workaround, use the `QuerySet.defer` method in conjunction with `distinct()` to prevent `TextField` columns from being included in the `SELECT DISTINCT` list.

## 6.7.6 Using a 3rd-party database backend

In addition to the officially supported databases, there are backends provided by 3rd parties that allow you to use other databases with Django:

- SAP SQL Anywhere
- IBM DB2
- Microsoft SQL Server
- Firebird
- ODBC

The Django versions and ORM features supported by these unofficial backends vary considerably. Queries regarding the specific capabilities of these unofficial backends, along with any support queries, should be directed to the support channels provided by each 3rd party project.

## 6.8 `django-admin` and `manage.py`

`django-admin` is Django's command-line utility for administrative tasks. This document outlines all it can do.

In addition, `manage.py` is automatically created in each Django project. `manage.py` does the same thing as `django-admin` but takes care of a few things for you:

- It puts your project's package on `sys.path`.
- It sets the `DJANGO_SETTINGS_MODULE` environment variable so that it points to your project's `settings.py` file.

The `django-admin` script should be on your system path if you installed Django via its `setup.py` utility. If it's not on your path, you can find it in `site-packages/django/bin` within your Python installation. Consider symlinking it from some place on your path, such as `/usr/local/bin`.

For Windows users, who do not have symlinking functionality available, you can copy `django-admin.exe` to a location on your existing path or edit the `PATH` settings (under Settings - Control Panel - System - Advanced - Environment...) to point to its installed location.

Generally, when working on a single Django project, it's easier to use `manage.py` than `django-admin`. If you need to switch between multiple Django settings files, use `django-admin` with `DJANGO_SETTINGS_MODULE` or the `--settings` command line option.

The command-line examples throughout this document use `django-admin` to be consistent, but any example can use `manage.py` or `python -m django` just as well.

`python -m django` was added.

### 6.8.1 Usage

```
$ django-admin <command> [options]
$ manage.py <command> [options]
$ python -m django <command> [options]
```

`command` should be one of the commands listed in this document. `options`, which is optional, should be zero or more of the options available for the given command.

## Getting runtime help

### `django-admin help`

Run `django-admin help` to display usage information and a list of the commands provided by each application.

Run `django-admin help --commands` to display a list of all available commands.

Run `django-admin help <command>` to display a description of the given command and a list of its available options.

## App names

Many commands take a list of “app names.” An “app name” is the basename of the package containing your models. For example, if your `INSTALLED_APPS` contains the string `'mysite.blog'`, the app name is `blog`.

## Determining the version

### `django-admin version`

Run `django-admin version` to display the current Django version.

The output follows the schema described in [PEP 440](#):

```
1.4.dev17026
1.4a1
1.4
```

## Displaying debug output

Use `--verbosity` to specify the amount of notification and debug information that `django-admin` prints to the console.

## 6.8.2 Available commands

### `check`

`django-admin check [app_label [app_label ...]]`

Uses the *system check framework* to inspect the entire Django project for common problems.

By default, all apps will be checked. You can check a subset of apps by providing a list of app labels as arguments:

```
django-admin check auth admin myapp
```

If you do not specify any app, all apps will be checked.

`--tag TAGS, -t TAGS`

The system check framework performs many different types of checks that are *categorized with tags*. You can use these tags to restrict the checks performed to just those in a particular category. For example, to perform only models and compatibility checks, run:

```
django-admin check --tag models --tag compatibility
```

`--list-tags`

Lists all available tags.

### **--deploy**

Activates some additional checks that are only relevant in a deployment setting.

You can use this option in your local development environment, but since your local development settings module may not have many of your production settings, you will probably want to point the `check` command at a different settings module, either by setting the `DJANGO_SETTINGS_MODULE` environment variable, or by passing the `--settings` option:

```
django-admin check --deploy --settings=production_settings
```

Or you could run it directly on a production or staging deployment to verify that the correct settings are in use (omitting `--settings`). You could even make it part of your integration test suite.

**--fail-level** {CRITICAL, ERROR, WARNING, INFO, DEBUG}

Specifies the message level that will cause the command to exit with a non-zero status. Default is ERROR.

## **compilemessages**

### **django-admin compilemessages**

Compiles `.po` files created by `makemessages` to `.mo` files for use with the built-in gettext support. See *Internationalization and localization*.

**--locale** LOCALE, **-l** LOCALE

Specifies the locale(s) to process. If not provided, all locales are processed.

**--exclude** EXCLUDE, **-x** EXCLUDE

Specifies the locale(s) to exclude from processing. If not provided, no locales are excluded.

**--use-fuzzy**, **-f**

Includes fuzzy translations into compiled files.

`compilemessages` now matches the operation of `makemessages`, scanning the project tree for `.po` files to compile.

Example usage:

```
django-admin compilemessages --locale=pt_BR
django-admin compilemessages --locale=pt_BR --locale=fr -f
django-admin compilemessages -l pt_BR
django-admin compilemessages -l pt_BR -l fr --use-fuzzy
django-admin compilemessages --exclude=pt_BR
django-admin compilemessages --exclude=pt_BR --exclude=fr
django-admin compilemessages -x pt_BR
django-admin compilemessages -x pt_BR -x fr
```

## **createcachetable**

### **django-admin createcachetable**

Creates the cache tables for use with the database cache backend using the information from your settings file. See *Django's cache framework* for more information.

**--database** DATABASE

Specifies the database in which the cache table(s) will be created. Defaults to `default`.

### **--dry-run**

Prints the SQL that would be run without actually running it, so you can customize it or use the migrations framework.

The `--dry-run` option was added.

## **dbshell**

### **django-admin dbshell**

Runs the command-line client for the database engine specified in your `ENGINE` setting, with the connection parameters specified in your `USER`, `PASSWORD`, etc., settings.

- For PostgreSQL, this runs the `psql` command-line client.
- For MySQL, this runs the `mysql` command-line client.
- For SQLite, this runs the `sqlite3` command-line client.
- For Oracle, this runs the `sqlplus` command-line client.

This command assumes the programs are on your `PATH` so that a simple call to the program name (`psql`, `mysql`, `sqlite3`, `sqlplus`) will find the program in the right place. There's no way to specify the location of the program manually.

### **--database** DATABASE

Specifies the database onto which to open a shell. Defaults to `default`.

## **diffsettings**

### **django-admin diffsettings**

Displays differences between the current settings file and Django's default settings.

Settings that don't appear in the defaults are followed by `###`. For example, the default settings don't define `ROOT_URLCONF`, so `ROOT_URLCONF` is followed by `###` in the output of `diffsettings`.

### **--all**

Displays all settings, even if they have Django's default value. Such settings are prefixed by `###`.

## **dumpdata**

### **django-admin dumpdata** [app\_label[.ModelName] [app\_label[.ModelName] ...]]

Outputs to standard output all data in the database associated with the named application(s).

If no application name is provided, all installed applications will be dumped.

The output of `dumpdata` can be used as input for `loaddata`.

Note that `dumpdata` uses the default manager on the model for selecting the records to dump. If you're using a *custom manager* as the default manager and it filters some of the available records, not all of the objects will be dumped.

### **--all, -a**

Uses Django's base manager, dumping records which might otherwise be filtered or modified by a custom manager.

### **--format** FORMAT

Specifies the serialization format of the output. Defaults to JSON. Supported formats are listed in *Serialization formats*.

**--indent** INDENT

Specifies the number of indentation spaces to use in the output. Defaults to `None` which displays all data on single line.

**--exclude** EXCLUDE, **-e** EXCLUDE

Prevents specific applications or models (specified in the form of `app_label.ModelName`) from being dumped. If you specify a model name, the output will be restricted to that model, rather than the entire application. You can also mix application names and model names.

If you want to exclude multiple applications, pass `--exclude` more than once:

```
django-admin dumpdata --exclude=auth --exclude=contenttypes
```

**--database** DATABASE

Specifies the database from which data will be dumped. Defaults to `default`.

**--natural-foreign**

Uses the `natural_key()` model method to serialize any foreign key and many-to-many relationship to objects of the type that defines the method. If you're dumping `contrib.auth` `Permission` objects or `contrib.contenttypes` `ContentType` objects, you should probably use this flag. See the *natural keys* documentation for more details on this and the next option.

**--natural-primary**

Omits the primary key in the serialized data of this object since it can be calculated during deserialization.

**--pks** PRIMARY\_KEYS

Outputs only the objects specified by a comma separated list of primary keys. This is only available when dumping one model. By default, all the records of the model are output.

**--output** OUTPUT, **-o** OUTPUT

Specifies a file to write the serialized data to. By default, the data goes to standard output.

When this option is set and `--verbosity` is greater than 0 (the default), a progress bar is shown in the terminal.

The progress bar in the terminal was added.

## flush

**django-admin flush**

Removes all data from the database and re-executes any post-synchronization handlers. The table of which migrations have been applied is not cleared.

If you would rather start from an empty database and re-run all migrations, you should drop and recreate the database and then run `migrate` instead.

**--noinput**, **--no-input**

Suppresses all user prompts.

The `--no-input` alias was added.

**--database** DATABASE

Specifies the database to flush. Defaults to `default`.

## inspectdb

### **django-admin inspectdb [table [table ...]]**

Introspects the database tables in the database pointed-to by the *NAME* setting and outputs a Django model module (a `models.py` file) to standard output. You may choose what tables to inspect by passing their names as arguments.

Use this if you have a legacy database with which you'd like to use Django. The script will inspect the database and create a model for each table within it.

As you might expect, the created models will have an attribute for every field in the table. Note that `inspectdb` has a few special cases in its field-name output:

- If `inspectdb` cannot map a column's type to a model field type, it'll use `TextField` and will insert the Python comment `'This field type is a guess.'` next to the field in the generated model.
- If the database column name is a Python reserved word (such as `'pass'`, `'class'` or `'for'`), `inspectdb` will append `'_field'` to the attribute name. For example, if a table has a column `'for'`, the generated model will have a field `'for_field'`, with the `db_column` attribute set to `'for'`. `inspectdb` will insert the Python comment `'Field renamed because it was a Python reserved word.'` next to the field.

This feature is meant as a shortcut, not as definitive model generation. After you run it, you'll want to look over the generated models yourself to make customizations. In particular, you'll need to rearrange models' order, so that models that refer to other models are ordered properly.

Primary keys are automatically introspected for PostgreSQL, MySQL and SQLite, in which case Django puts in the `primary_key=True` where needed.

`inspectdb` works with PostgreSQL, MySQL and SQLite. Foreign-key detection only works in PostgreSQL and with certain types of MySQL tables.

Django doesn't create database defaults when a *default* is specified on a model field. Similarly, database defaults aren't translated to model field defaults or detected in any fashion by `inspectdb`.

By default, `inspectdb` creates unmanaged models. That is, `managed = False` in the model's `Meta` class tells Django not to manage each table's creation, modification, and deletion. If you do want to allow Django to manage the table's lifecycle, you'll need to change the *managed* option to `True` (or simply remove it because `True` is its default value).

Support for the `table` argument(s) to choose what tables should be inspected was added.

**--database** DATABASE

Specifies the database to introspect. Defaults to `default`.

## loaddata

### **django-admin loaddata fixture [fixture ...]**

Searches for and loads the contents of the named fixture into the database.

**--database** DATABASE

Specifies the database into which the data will be loaded. Defaults to `default`.

**--ignorenonexistent, -i**

Ignores fields and models that may have been removed since the fixture was originally generated.

**--app** APP\_LABEL

Specifies a single app to look for fixtures in rather than looking in all apps.

## What's a “fixture”?

A *fixture* is a collection of files that contain the serialized contents of the database. Each fixture has a unique name, and the files that comprise the fixture can be distributed over multiple directories, in multiple applications.

Django will search in three locations for fixtures:

1. In the `fixtures` directory of every installed application
2. In any directory named in the `FIXTURE_DIRS` setting
3. In the literal path named by the fixture

Django will load any and all fixtures it finds in these locations that match the provided fixture names.

If the named fixture has a file extension, only fixtures of that type will be loaded. For example:

```
django-admin loaddata mydata.json
```

would only load JSON fixtures called `mydata`. The fixture extension must correspond to the registered name of a *serializer* (e.g., `json` or `xml`).

If you omit the extensions, Django will search all available fixture types for a matching fixture. For example:

```
django-admin loaddata mydata
```

would look for any fixture of any fixture type called `mydata`. If a fixture directory contained `mydata.json`, that fixture would be loaded as a JSON fixture.

The fixtures that are named can include directory components. These directories will be included in the search path. For example:

```
django-admin loaddata foo/bar/mydata.json
```

would search `<app_label>/fixtures/foo/bar/mydata.json` for each installed application, `<dirname>/foo/bar/mydata.json` for each directory in `FIXTURE_DIRS`, and the literal path `foo/bar/mydata.json`.

When fixture files are processed, the data is saved to the database as is. Model defined `save()` methods are not called, and any `pre_save` or `post_save` signals will be called with `raw=True` since the instance only contains attributes that are local to the model. You may, for example, want to disable handlers that access related fields that aren't present during fixture loading and would otherwise raise an exception:

```
from django.db.models.signals import post_save
from .models import MyModel

def my_handler(**kwargs):
    # disable the handler during fixture loading
    if kwargs['raw']:
        return
    ...

post_save.connect(my_handler, sender=MyModel)
```

You could also write a simple decorator to encapsulate this logic:

```
from functools import wraps

def disable_for_loaddata(signal_handler):
    """
```

```
Decorator that turns off signal handlers when loading fixture data.
"""
@wraps(signal_handler)
def wrapper(*args, **kwargs):
    if kwargs['raw']:
        return
    signal_handler(*args, **kwargs)
    return wrapper

@disable_for_loaddata
def my_handler(**kwargs):
    ...
```

Just be aware that this logic will disable the signals whenever fixtures are deserialized, not just during `loaddata`.

Note that the order in which fixture files are processed is undefined. However, all fixture data is installed as a single transaction, so data in one fixture can reference data in another fixture. If the database backend supports row-level constraints, these constraints will be checked at the end of the transaction.

The `dumpdata` command can be used to generate input for `loaddata`.

### Compressed fixtures

Fixtures may be compressed in `zip`, `gz`, or `bz2` format. For example:

```
django-admin loaddata mydata.json
```

would look for any of `mydata.json`, `mydata.json.zip`, `mydata.json.gz`, or `mydata.json.bz2`. The first file contained within a zip-compressed archive is used.

Note that if two fixtures with the same name but different fixture type are discovered (for example, if `mydata.json` and `mydata.xml.gz` were found in the same fixture directory), fixture installation will be aborted, and any data installed in the call to `loaddata` will be removed from the database.

---

### MySQL with MyISAM and fixtures

The MyISAM storage engine of MySQL doesn't support transactions or constraints, so if you use MyISAM, you won't get validation of fixture data, or a rollback if multiple transaction files are found.

---

### Database-specific fixtures

If you're in a multi-database setup, you might have fixture data that you want to load onto one database, but not onto another. In this situation, you can add a database identifier into the names of your fixtures.

For example, if your `DATABASES` setting has a 'master' database defined, name the fixture `mydata.master.json` or `mydata.master.json.gz` and the fixture will only be loaded when you specify you want to load data into the master database.

### makemessages

`django-admin makemessages`

Runs over the entire source tree of the current directory and pulls out all strings marked for translation. It creates (or updates) a message file in the `conf/locale` (in the Django tree) or `locale` (for project and application) directory. After making changes to the messages files you need to compile them with `compilemessages` for use with the builtin gettext support. See the *18n documentation* for details.

**--all, -a**

Updates the message files for all available languages.

**--extension EXTENSIONS, -e EXTENSIONS**

Specifies a list of file extensions to examine (default: `html,txt,py` or `js` if `--domain` is `js`).

Example usage:

```
django-admin makemessages --locale=de --extension xhtml
```

Separate multiple extensions with commas or use `-e` or `--extension` multiple times:

```
django-admin makemessages --locale=de --extension=html,txt --extension xml
```

**--locale LOCALE, -l LOCALE**

Specifies the locale(s) to process.

**--exclude EXCLUDE, -x EXCLUDE**

Specifies the locale(s) to exclude from processing. If not provided, no locales are excluded.

Example usage:

```
django-admin makemessages --locale=pt_BR
django-admin makemessages --locale=pt_BR --locale=fr
django-admin makemessages -l pt_BR
django-admin makemessages -l pt_BR -l fr
django-admin makemessages --exclude=pt_BR
django-admin makemessages --exclude=pt_BR --exclude=fr
django-admin makemessages -x pt_BR
django-admin makemessages -x pt_BR -x fr
```

**--domain DOMAIN, -d DOMAIN**

Specifies the domain of the messages files. Supported options are:

- `django` for all `*.py`, `*.html` and `*.txt` files (default)
- `djangojs` for `*.js` files

**--symlinks, -s**

Follows symlinks to directories when looking for new translation strings.

Example usage:

```
django-admin makemessages --locale=de --symlinks
```

**--ignore PATTERN, -i PATTERN**

Ignores files or directories matching the given `glob`-style pattern. Use multiple times to ignore more.

These patterns are used by default: `'CVS'`, `'.'`, `'*~'`, `'*.pyc'`.

Example usage:

```
django-admin makemessages --locale=en_US --ignore=apps/* --ignore=secret/*.html
```

**--no-default-ignore**

Disables the default values of `--ignore`.

**--no-wrap**

Disables breaking long message lines into several lines in language files.

**--no-location**

Suppresses writing `'#: filename:line'` comment lines in language files. Using this option makes it harder for technically skilled translators to understand each message's context.

**--keep-pot**

Prevents deleting the temporary `.pot` files generated before creating the `.po` file. This is useful for debugging errors which may prevent the final language files from being created.

**See also:**

See *Customizing the makemessages command* for instructions on how to customize the keywords that `makemessages` passes to `xgettext`.

**makemigrations**

```
django-admin makemigrations [app_label [app_label ...]]
```

Creates new migrations based on the changes detected to your models. Migrations, their relationship with apps and more are covered in depth in *the migrations documentation*.

Providing one or more app names as arguments will limit the migrations created to the app(s) specified and any dependencies needed (the table at the other end of a `ForeignKey`, for example).

**--noinput, --no-input**

Suppresses all user prompts. If a suppressed prompt cannot be resolved automatically, the command will exit with error code 3.

The `--no-input` alias was added.

**--empty**

Outputs an empty migration for the specified apps, for manual editing. This is for advanced users and should not be used unless you are familiar with the migration format, migration operations, and the dependencies between your migrations.

**--dry-run**

Shows what migrations would be made without actually writing any migrations files to disk. Using this option along with `--verbosity 3` will also show the complete migrations files that would be written.

**--merge**

Enables fixing of migration conflicts.

**--name** NAME, **-n** NAME

Allows naming the generated migration(s) instead of using a generated name.

**--exit, -e**

Deprecated since version 1.10: Use the `--check` option instead.

Makes `makemigrations` exit with error code 1 when no migrations are created (or would have been created, if combined with `--dry-run`).

#### **`--check`**

Makes `makemigrations` exit with a non-zero status when model changes without migrations are detected.

### **`migrate`**

**`django-admin migrate [app_label] [migration_name]`**

Synchronizes the database state with the current set of models and migrations. Migrations, their relationship with apps and more are covered in depth in [the migrations documentation](#).

The behavior of this command changes depending on the arguments provided:

- No arguments: All apps have all of their migrations run.
- `<app_label>`: The specified app has its migrations run, up to the most recent migration. This may involve running other apps' migrations too, due to dependencies.
- `<app_label> <migrationname>`: Brings the database schema to a state where the named migration is applied, but no later migrations in the same app are applied. This may involve unapplying migrations if you have previously migrated past the named migration. Use the name `zero` to unapply all migrations for an app.

#### **`--database DATABASE`**

Specifies the database to migrate. Defaults to `default`.

#### **`--fake`**

Tells Django to mark the migrations as having been applied or unapplied, but without actually running the SQL to change your database schema.

This is intended for advanced users to manipulate the current migration state directly if they're manually applying changes; be warned that using `--fake` runs the risk of putting the migration state table into a state where manual recovery will be needed to make migrations run correctly.

#### **`--fake-initial`**

Allows Django to skip an app's initial migration if all database tables with the names of all models created by all `CreateModel` operations in that migration already exist. This option is intended for use when first running migrations against a database that preexisted the use of migrations. This option does not, however, check for matching database schema beyond matching table names and so is only safe to use if you are confident that your existing schema matches what is recorded in your initial migration.

#### **`--run-syncdb`**

Allows creating tables for apps without migrations. While this isn't recommended, the migrations framework is sometimes too slow on large projects with hundreds of models.

#### **`--noinput, --no-input`**

Suppresses all user prompts. An example prompt is asking about removing stale content types.

The `--no-input` alias was added.

### **`runserver`**

**`django-admin runserver [addrport]`**

Starts a lightweight development Web server on the local machine. By default, the server runs on port 8000 on the IP address `127.0.0.1`. You can pass in an IP address and port number explicitly.

If you run this script as a user with normal privileges (recommended), you might not have access to start a port on a low port number. Low port numbers are reserved for the superuser (root).

This server uses the WSGI application object specified by the `WSGI_APPLICATION` setting.

DO NOT USE THIS SERVER IN A PRODUCTION SETTING. It has not gone through security audits or performance tests. (And that's how it's gonna stay. We're in the business of making Web frameworks, not Web servers, so improving this server to be able to handle a production environment is outside the scope of Django.)

The development server automatically reloads Python code for each request, as needed. You don't need to restart the server for code changes to take effect. However, some actions like adding files don't trigger a restart, so you'll have to restart the server in these cases.

If you are using Linux and install `pyinotify`, kernel signals will be used to autoreload the server (rather than polling file modification timestamps each second). This offers better scaling to large projects, reduction in response time to code modification, more robust change detection, and battery usage reduction.

When you start the server, and each time you change Python code while the server is running, the system check framework will check your entire Django project for some common errors (see the `check` command). If any errors are found, they will be printed to standard output.

You can run as many concurrent servers as you want, as long as they're on separate ports. Just execute `django-admin runserver` more than once.

Note that the default IP address, `127.0.0.1`, is not accessible from other machines on your network. To make your development server viewable to other machines on the network, use its own IP address (e.g. `192.168.2.1`) or `0.0.0.0` or `::` (with IPv6 enabled).

You can provide an IPv6 address surrounded by brackets (e.g. `[200a::1]:8000`). This will automatically enable IPv6 support.

A hostname containing ASCII-only characters can also be used.

If the `staticfiles` contrib app is enabled (default in new projects) the `runserver` command will be overridden with its own `runserver` command.

If `migrate` was not previously executed, the table that stores the history of migrations is created at first run of `runserver`.

Logging of each request and response of the server is sent to the `django.server` logger.

In older versions, log messages were written to `sys.stderr` instead of being handled through Python logging.

#### **--noreload**

Disables the auto-reloader. This means any Python code changes you make while the server is running will *not* take effect if the particular Python modules have already been loaded into memory.

#### **--nothreading**

Disables use of threading in the development server. The server is multithreaded by default.

#### **--ipv6, -6**

Uses IPv6 for the development server. This changes the default IP address from `127.0.0.1` to `:::1`.

### Examples of using different ports and addresses

Port 8000 on IP address `127.0.0.1`:

```
django-admin runserver
```

Port 8000 on IP address 1.2.3.4:

```
django-admin runserver 1.2.3.4:8000
```

Port 7000 on IP address 127.0.0.1:

```
django-admin runserver 7000
```

Port 7000 on IP address 1.2.3.4:

```
django-admin runserver 1.2.3.4:7000
```

Port 8000 on IPv6 address ::1:

```
django-admin runserver -6
```

Port 7000 on IPv6 address ::1:

```
django-admin runserver -6 7000
```

Port 7000 on IPv6 address 2001:0db8:1234:5678::9:

```
django-admin runserver [2001:0db8:1234:5678::9]:7000
```

Port 8000 on IPv4 address of host localhost:

```
django-admin runserver localhost:8000
```

Port 8000 on IPv6 address of host localhost:

```
django-admin runserver -6 localhost:8000
```

## Serving static files with the development server

By default, the development server doesn't serve any static files for your site (such as CSS files, images, things under `MEDIA_URL` and so forth). If you want to configure Django to serve static media, read *Managing static files (e.g. images, JavaScript, CSS)*.

### `sendtestemail`

```
django-admin sendtestemail [email [email ...]]
```

Sends a test email (to confirm email sending through Django is working) to the recipient(s) specified. For example:

```
django-admin sendtestemail foo@example.com bar@example.com
```

There are a couple of options, and you may use any combination of them together:

#### `--managers`

Mails the email addresses specified in `MANAGERS` using `mail_managers()`.

#### `--admins`

Mails the email addresses specified in `ADMINS` using `mail_admins()`.

## shell

### django-admin shell

Starts the Python interactive interpreter.

**--interface** {ipython,bpython,python}, **-i** {ipython,bpython,python}

Specifies the shell to use. By default, Django will use `IPython` or `bpython` if either is installed. If both are installed, specify which one you want like so:

IPython:

```
django-admin shell -i ipython
```

bpython:

```
django-admin shell -i bpython
```

If you have a “rich” shell installed but want to force use of the “plain” Python interpreter, use `python` as the interface name, like so:

```
django-admin shell -i python
```

Deprecated since version 1.10: In older versions, use the `--plain` option instead of `-i python`. This is deprecated and will be removed in Django 2.0.

### --nostartup

Disables reading the startup script for the “plain” Python interpreter. By default, the script pointed to by the `PYTHONSTARTUP` environment variable or the `~/ .pythonrc.py` script is read.

**--command** COMMAND, **-c** COMMAND

Lets you pass a command as a string to execute it as Django, like so:

```
django-admin shell --command="import django; print(django.__version__)"
```

## showmigrations

### django-admin showmigrations [app\_label [app\_label ...]]

Shows all migrations in a project. You can choose from one of two formats:

#### --list, -l

Lists all of the apps Django knows about, the migrations available for each app, and whether or not each migration is applied (marked by an `[X]` next to the migration name).

Apps without migrations are also listed, but have `(no migrations)` printed under them.

This is the default output format.

#### --plan, -p

Shows the migration plan Django will follow to apply migrations. Any supplied app labels are ignored because the plan might go beyond those apps. Like `--list`, applied migrations are marked by an `[X]`. For a `--verbosity` of 2 and above, all dependencies of a migration will also be shown.

**--database** DATABASE

Specifies the database to examine. Defaults to `default`.

### `sqlflush`

#### `django-admin sqlflush`

Prints the SQL statements that would be executed for the `flush` command.

`--database` DATABASE

Specifies the database for which to print the SQL. Defaults to `default`.

### `sqlmigrate`

#### `django-admin sqlmigrate app_label migration_name`

Prints the SQL for the named migration. This requires an active database connection, which it will use to resolve constraint names; this means you must generate the SQL against a copy of the database you wish to later apply it on.

Note that `sqlmigrate` doesn't colorize its output.

`--backwards`

Generates the SQL for unapplying the migration. By default, the SQL created is for running the migration in the forwards direction.

`--database` DATABASE

Specifies the database for which to generate the SQL. Defaults to `default`.

To increase the readability of the overall SQL output the SQL code generated for each migration operation is preceded by the operation's description.

### `sqlsequencereset`

#### `django-admin sqlsequencereset app_label [app_label ...]`

Prints the SQL statements for resetting sequences for the given app name(s).

Sequences are indexes used by some database engines to track the next available number for automatically incremented fields.

Use this command to generate SQL which will fix cases where a sequence is out of sync with its automatically incremented field data.

`--database` DATABASE

Specifies the database for which to print the SQL. Defaults to `default`.

### `squashmigrations`

#### `django-admin squashmigrations app_label [start_migration_name] migration_name`

Squashes the migrations for `app_label` up to and including `migration_name` down into fewer migrations, if possible. The resulting squashed migrations can live alongside the unsquashed ones safely. For more information, please read *Squashing migrations*.

When `start_migration_name` is given, Django will only include migrations starting from and including this migration. This helps to mitigate the squashing limitation of `RunPython` and `django.db.migrations.operations.RunSQL` migration operations.

`--no-optimize`

Disables the optimizer when generating a squashed migration. By default, Django will try to optimize the operations in your migrations to reduce the size of the resulting file. Use this option if this process is failing or creating incorrect migrations, though please also file a Django bug report about the behavior, as optimization is meant to be safe.

**--noinput, --no-input**

Suppresses all user prompts.

The `--no-input` alias was added.

## startapp

**django-admin startapp name [directory]**

Creates a Django app directory structure for the given app name in the current directory or the given destination.

By default the directory created contains a `models.py` file and other app template files. (See the [source](#) for more details.) If only the app name is given, the app directory will be created in the current working directory.

If the optional destination is provided, Django will use that existing directory rather than creating a new one. You can use `.` to denote the current working directory.

For example:

```
django-admin startapp myapp /Users/jezdez/Code/myapp
```

**--template TEMPLATE**

Provides the path to a directory with a custom app template file or a path to a compressed file (`.tar.gz`, `.tar.bz2`, `.tgz`, `.tbz`, `.zip`) containing the app template files.

For example, this would look for an app template in the given directory when creating the `myapp` app:

```
django-admin startapp --template=/Users/jezdez/Code/my_app_template myapp
```

Django will also accept URLs (`http`, `https`, `ftp`) to compressed archives with the app template files, downloading and extracting them on the fly.

For example, taking advantage of GitHub's feature to expose repositories as zip files, you can use a URL like:

```
django-admin startapp --template=https://github.com/githubuser/django-app-template/
↪archive/master.zip myapp
```

**--extension EXTENSIONS, -e EXTENSIONS**

Specifies which file extensions in the app template should be rendered with the template engine. Defaults to `py`.

**--name FILES, -n FILES**

Specifies which files in the app template (in addition to those matching `--extension`) should be rendered with the template engine. Defaults to an empty list.

The *template context* used for all matching files is:

- Any option passed to the `startapp` command (among the command's supported options)
- `app_name` – the app name as passed to the command
- `app_directory` – the full path of the newly created app
- `camel_case_app_name` – the app name in camel case format
- `docs_version` – the version of the documentation: `'dev'` or `'1.x'`

camel\_case\_app\_name was added.

**Warning:** When the app template files are rendered with the Django template engine (by default all \*.py files), Django will also replace all stray template variables contained. For example, if one of the Python files contains a docstring explaining a particular feature related to template rendering, it might result in an incorrect example.

To work around this problem, you can use the `templatetag` templatetag to “escape” the various parts of the template syntax.

In addition, to allow Python template files that contain Django template language syntax while also preventing packaging systems from trying to byte-compile invalid \*.py files, template files ending with `.py-tpl` will be renamed to `.py`.

Renaming of `.py-tpl` to `.py` was added.

## startproject

### `django-admin startproject name [directory]`

Creates a Django project directory structure for the given project name in the current directory or the given destination.

By default, the new directory contains `manage.py` and a project package (containing a `settings.py` and other files). See the [template source](#) for details.

If only the project name is given, both the project directory and project package will be named `<projectname>` and the project directory will be created in the current working directory.

If the optional destination is provided, Django will use that existing directory as the project directory, and create `manage.py` and the project package within it. Use `.` to denote the current working directory.

For example:

```
django-admin startproject myproject /Users/jezdez/Code/myproject_repo
```

**--template** TEMPLATE

Specifies a directory, file path, or URL of a custom project template. See the [startapp --template](#) documentation for examples and usage.

**--extension** EXTENSIONS, **-e** EXTENSIONS

Specifies which file extensions in the project template should be rendered with the template engine. Defaults to `py`.

**--name** FILES, **-n** FILES

Specifies which files in the project template (in addition to those matching `--extension`) should be rendered with the template engine. Defaults to an empty list.

The `template context` used is:

- Any option passed to the `startproject` command (among the command’s supported options)
- `project_name` – the project name as passed to the command
- `project_directory` – the full path of the newly created project
- `secret_key` – a random key for the `SECRET_KEY` setting
- `docs_version` – the version of the documentation: `'dev'` or `'1.x'`

Please also see the [rendering warning](#) as mentioned for [startapp](#).

## test

**django-admin test** [**test\_label** [**test\_label ...**]]

Runs tests for all installed apps. See *Testing in Django* for more information.

**--failfast**

Stops running tests and reports the failure immediately after a test fails.

**--testrunner** TESTRUNNER

Controls the test runner class that is used to execute tests. This value overrides the value provided by the `TEST_RUNNER` setting.

**--liveserver** LIVESERVER

Overrides the default address where the live server (used with `LiveServerTestCase`) is expected to run from. The default value is `localhost:8081-8179`.

In earlier versions, the default value was `localhost:8081`.

**--noinput, --no-input**

Suppresses all user prompts. A typical prompt is a warning about deleting an existing test database.

The `--no-input` alias was added.

## Test runner options

The `test` command receives options on behalf of the specified `--testrunner`. These are the options of the default test runner: `DiscoverRunner`.

**--keepdb, -k**

Preserves the test database between test runs. This has the advantage of skipping both the create and destroy actions which can greatly decrease the time to run tests, especially those in a large test suite. If the test database does not exist, it will be created on the first run and then preserved for each subsequent run. Any unapplied migrations will also be applied to the test database before running the test suite.

**--reverse, -r**

Sorts test cases in the opposite execution order. This may help in debugging the side effects of tests that aren't properly isolated. *Grouping by test class* is preserved when using this option.

**--debug-sql, -d**

Enables *SQL logging* for failing tests. If `--verbosity` is 2, then queries in passing tests are also output.

**--parallel** [N]

Runs tests in separate parallel processes. Since modern processors have multiple cores, this allows running tests significantly faster.

By default `--parallel` runs one process per core according to `multiprocessing.cpu_count()`. You can adjust the number of processes either by providing it as the option's value, e.g. `--parallel=4`, or by setting the `DJANGO_TEST_PROCESSES` environment variable.

Django distributes test cases — `unittest.TestCase` subclasses — to subprocesses. If there are fewer test cases than configured processes, Django will reduce the number of processes accordingly.

Each process gets its own database. You must ensure that different test cases don't access the same resources. For instance, test cases that touch the filesystem should create a temporary directory for their own use.

This option requires the third-party `tblib` package to display tracebacks correctly:

```
$ pip install tblib
```

This feature isn't available on Windows. It doesn't work with the Oracle database backend either.

If you want to use `pdb` while debugging tests, you must disable parallel execution (`--parallel=1`). You'll see something like `bdb.BdbQuit` if you don't.

**Warning:** When test parallelization is enabled and a test fails, Django may be unable to display the exception traceback. This can make debugging difficult. If you encounter this problem, run the affected test without parallelization to see the traceback of the failure.

This is a known limitation. It arises from the need to serialize objects in order to exchange them between processes. See [What can be pickled and unpickled?](#) for details.

**--tag** TAGS

Runs only tests *marked with the specified tags*. May be specified multiple times and combined with `test --exclude-tag`.

**--exclude-tag** EXCLUDE\_TAGS

Excludes tests *marked with the specified tags*. May be specified multiple times and combined with `test --tag`.

### testserver

**django-admin testserver** [**fixture** [**fixture** ...]]

Runs a Django development server (as in `runserver`) using data from the given fixture(s).

For example, this command:

```
django-admin testserver mydata.json
```

...would perform the following steps:

1. Create a test database, as described in *The test database*.
2. Populate the test database with fixture data from the given fixtures. (For more on fixtures, see the documentation for `loaddata` above.)
3. Runs the Django development server (as in `runserver`), pointed at this newly created test database instead of your production database.

This is useful in a number of ways:

- When you're writing *unit tests* of how your views act with certain fixture data, you can use `testserver` to interact with the views in a Web browser, manually.
- Let's say you're developing your Django application and have a "pristine" copy of a database that you'd like to interact with. You can dump your database to a fixture (using the `dumpdata` command, explained above), then use `testserver` to run your Web application with that data. With this arrangement, you have the flexibility of messing up your data in any way, knowing that whatever data changes you're making are only being made to a test database.

Note that this server does *not* automatically detect changes to your Python source code (as `runserver` does). It does, however, detect changes to templates.

**--addrport** ADDRPORT

Specifies a different port, or IP address and port, from the default of `127.0.0.1:8000`. This value follows exactly the same format and serves exactly the same function as the argument to the `runserver` command.

Examples:

To run the test server on port 7000 with `fixture1` and `fixture2`:

```
django-admin testserver --addrport 7000 fixture1 fixture2
django-admin testserver fixture1 fixture2 --addrport 7000
```

(The above statements are equivalent. We include both of them to demonstrate that it doesn't matter whether the options come before or after the fixture arguments.)

To run on `1.2.3.4:7000` with a `test` fixture:

```
django-admin testserver --addrport 1.2.3.4:7000 test
```

#### **--noinput, --no-input**

Suppresses all user prompts. A typical prompt is a warning about deleting an existing test database.

The `--no-input` alias was added.

### 6.8.3 Commands provided by applications

Some commands are only available when the `django.contrib` application that *implements* them has been *enabled*. This section describes them grouped by their application.

#### **django.contrib.auth**

##### **changepassword**

**django-admin changepassword [<username>]**

This command is only available if Django's *authentication system* (`django.contrib.auth`) is installed.

Allows changing a user's password. It prompts you to enter a new password twice for the given user. If the entries are identical, this immediately becomes the new password. If you do not supply a user, the command will attempt to change the password whose username matches the current user.

**--database** DATABASE

Specifies the database to query for the user. Defaults to `default`.

Example usage:

```
django-admin changepassword ringo
```

##### **createsuperuser**

**django-admin createsuperuser**

This command is only available if Django's *authentication system* (`django.contrib.auth`) is installed.

Creates a superuser account (a user who has all permissions). This is useful if you need to create an initial superuser account or if you need to programmatically generate superuser accounts for your site(s).

When run interactively, this command will prompt for a password for the new superuser account. When run non-interactively, no password will be set, and the superuser account will not be able to log in until a password has been manually set for it.

**--username** USERNAME

**--email** EMAIL

The username and email address for the new account can be supplied by using the `--username` and `--email` arguments on the command line. If either of those is not supplied, `createsuperuser` will prompt for it when running interactively.

**--database** DATABASE

Specifies the database into which the superuser object will be saved.

You can subclass the management command and override `get_input_data()` if you want to customize data input and validation. Consult the source code for details on the existing implementation and the method's parameters. For example, it could be useful if you have a `ForeignKey` in `REQUIRED_FIELDS` and want to allow creating an instance instead of entering the primary key of an existing instance.

### `django.contrib.gis`

#### `ogrinspect`

This command is only available if *GeoDjango* (`django.contrib.gis`) is installed.

Please refer to its *description* in the GeoDjango documentation.

### `django.contrib.sessions`

#### `clearsessions`

#### `django-admin clearsessions`

Can be run as a cron job or directly to clean out expired sessions.

### `django.contrib.sitemaps`

#### `ping_google`

This command is only available if the *Sitemaps framework* (`django.contrib.sitemaps`) is installed.

Please refer to its *description* in the Sitemaps documentation.

### `django.contrib.staticfiles`

#### `collectstatic`

This command is only available if the *static files application* (`django.contrib.staticfiles`) is installed.

Please refer to its *description* in the *staticfiles* documentation.

## findstatic

This command is only available if the *static files application* (`django.contrib.staticfiles`) is installed.

Please refer to its *description* in the *staticfiles* documentation.

## 6.8.4 Default options

Although some commands may allow their own custom options, every command allows for the following options:

**--pythonpath** PYTHONPATH

Adds the given filesystem path to the Python `import` search path. If this isn't provided, `django-admin` will use the `PYTHONPATH` environment variable.

This option is unnecessary in `manage.py`, because it takes care of setting the Python path for you.

Example usage:

```
django-admin migrate --pythonpath='/home/djangoprojects/myproject'
```

**--settings** SETTINGS

Specifies the settings module to use. The settings module should be in Python package syntax, e.g. `mysite.settings`. If this isn't provided, `django-admin` will use the `DJANGO_SETTINGS_MODULE` environment variable.

This option is unnecessary in `manage.py`, because it uses `settings.py` from the current project by default.

Example usage:

```
django-admin migrate --settings=mysite.settings
```

**--traceback**

Displays a full stack trace when a `CommandError` is raised. By default, `django-admin` will show a simple error message when a `CommandError` occurs and a full stack trace for any other exception.

Example usage:

```
django-admin migrate --traceback
```

**--verbosity** {0,1,2,3}, **-v** {0,1,2,3}

Specifies the amount of notification and debug information that a command should print to the console.

- 0 means no output.
- 1 means normal output (default).
- 2 means verbose output.
- 3 means *very* verbose output.

Example usage:

```
django-admin migrate --verbosity 2
```

**--no-color**

Disables colored command output. Some commands format their output to be colored. For example, errors will be printed to the console in red and SQL statements will be syntax highlighted.

Example usage:

```
django-admin runserver --no-color
```

## 6.8.5 Extra niceties

### Syntax coloring

The `django-admin / manage.py` commands will use pretty color-coded output if your terminal supports ANSI-colored output. It won't use the color codes if you're piping the command's output to another program.

Under Windows, the native console doesn't support ANSI escape sequences so by default there is no color output. But you can install the [ANSICON](#) third-party tool, the Django commands will detect its presence and will make use of its services to color output just like on Unix-based platforms.

The colors used for syntax highlighting can be customized. Django ships with three color palettes:

- `dark`, suited to terminals that show white text on a black background. This is the default palette.
- `light`, suited to terminals that show black text on a white background.
- `nocolor`, which disables syntax highlighting.

You select a palette by setting a `DJANGO_COLORS` environment variable to specify the palette you want to use. For example, to specify the `light` palette under a Unix or OS/X BASH shell, you would run the following at a command prompt:

```
export DJANGO_COLORS="light"
```

You can also customize the colors that are used. Django specifies a number of roles in which color is used:

- `error` - A major error.
- `notice` - A minor error.
- `success` - A success.
- `warning` - A warning.
- `sql_field` - The name of a model field in SQL.
- `sql_coltype` - The type of a model field in SQL.
- `sql_keyword` - An SQL keyword.
- `sql_table` - The name of a model in SQL.
- `http_info` - A 1XX HTTP Informational server response.
- `http_success` - A 2XX HTTP Success server response.
- `http_not_modified` - A 304 HTTP Not Modified server response.
- `http_redirect` - A 3XX HTTP Redirect server response other than 304.
- `http_not_found` - A 404 HTTP Not Found server response.
- `http_bad_request` - A 4XX HTTP Bad Request server response other than 404.
- `http_server_error` - A 5XX HTTP Server Error response.

- `migrate_heading` - A heading in a migrations management command.
- `migrate_label` - A migration name.

success was added.

Each of these roles can be assigned a specific foreground and background color, from the following list:

- `black`
- `red`
- `green`
- `yellow`
- `blue`
- `magenta`
- `cyan`
- `white`

Each of these colors can then be modified by using the following display options:

- `bold`
- `underscore`
- `blink`
- `reverse`
- `conceal`

A color specification follows one of the following patterns:

- `role=fg`
- `role=fg/bg`
- `role=fg, option, option`
- `role=fg/bg, option, option`

where `role` is the name of a valid color role, `fg` is the foreground color, `bg` is the background color and each `option` is one of the color modifying options. Multiple color specifications are then separated by a semicolon. For example:

```
export DJANGO_COLORS="error=yellow/blue,blink;notice=magenta"
```

would specify that errors be displayed using blinking yellow on blue, and notices displayed using magenta. All other color roles would be left uncolored.

Colors can also be specified by extending a base palette. If you put a palette name in a color specification, all the colors implied by that palette will be loaded. So:

```
export DJANGO_COLORS="light;error=yellow/blue,blink;notice=magenta"
```

would specify the use of all the colors in the `light` color palette, *except* for the colors for errors and notices which would be overridden as specified.

## Bash completion

If you use the Bash shell, consider installing the Django bash completion script, which lives in `extras/django_bash_completion` in the Django distribution. It enables tab-completion of `django-admin` and `manage.py` commands, so you can, for instance...

- Type `django-admin`.
- Press [TAB] to see all available options.
- Type `sql`, then [TAB], to see all available options whose names start with `sql`.

See *Writing custom django-admin commands* for how to add customized actions.

## 6.9 Running management commands from your code

`django.core.management.call_command(name, *args, **options)`

To call a management command from code use `call_command`.

**name** the name of the command to call or a command object. Passing the name is preferred unless the object is required for testing.

**\*args** a list of arguments accepted by the command. Arguments are passed to the argument parser, so you can use the same style as you would on the command line. For example, `call_command('flush', '--verbosity=0')`.

**\*\*options** named options accepted on the command-line. Options are passed to the command without triggering the argument parser, which means you'll need to pass the correct type. For example, `call_command('flush', verbosity=0)` (zero must be an integer rather than a string).

Examples:

```
from django.core import management
from django.core.management.commands import loaddata

management.call_command('flush', verbosity=0, interactive=False)
management.call_command('loaddata', 'test_data', verbosity=0)
management.call_command(loaddata.Command(), 'test_data', verbosity=0)
```

Note that command options that take no arguments are passed as keywords with `True` or `False`, as you can see with the `interactive` option above.

Named arguments can be passed by using either one of the following syntaxes:

```
# Similar to the command line
management.call_command('dumpdata', '--natural-foreign')

# Named argument similar to the command line minus the initial dashes and
# with internal dashes replaced by underscores
management.call_command('dumpdata', natural_foreign=True)

# `use_natural_foreign_keys` is the option destination variable
management.call_command('dumpdata', use_natural_foreign_keys=True)
```

Command options which take multiple options are passed a list:

```
management.call_command('dumpdata', exclude=['contenttypes', 'auth'])
```

The return value of the `call_command()` function is the same as the return value of the `handle()` method of the command.

`call_command()` now returns the value received from the `command.handle()` method. It now also accepts a command object as the first argument.

### 6.9.1 Output redirection

Note that you can redirect standard output and error streams as all commands support the `stdout` and `stderr` options. For example, you could write:

```
with open('/path/to/command_output') as f:
    management.call_command('dumpdata', stdout=f)
```

## 6.10 Django Exceptions

Django raises some of its own exceptions as well as standard Python exceptions.

### 6.10.1 Django Core Exceptions

Django core exception classes are defined in `django.core.exceptions`.

#### **AppRegistryNotReady**

##### **exception AppRegistryNotReady**

This exception is raised when attempting to use models before the *app loading process*, which initializes the ORM, is complete.

#### **ObjectDoesNotExist**

##### **exception ObjectDoesNotExist**

The base class for *DoesNotExist* exceptions; a `try/except` for `ObjectDoesNotExist` will catch *DoesNotExist* exceptions for all models.

See `get()` for further information on *ObjectDoesNotExist* and *DoesNotExist*.

#### **FieldDoesNotExist**

##### **exception FieldDoesNotExist**

The `FieldDoesNotExist` exception is raised by a model's `_meta.get_field()` method when the requested field does not exist on the model or on the model's parents.

#### **MultipleObjectsReturned**

##### **exception MultipleObjectsReturned**

The *MultipleObjectsReturned* exception is raised by a query if only one object is expected, but multiple objects are returned. A base version of this exception is provided in `django.core.exceptions`; each model class contains a subclassed version that can be used to identify the specific object type that has returned multiple objects.

See `get ()` for further information.

## SuspiciousOperation

### exception SuspiciousOperation

The *SuspiciousOperation* exception is raised when a user has performed an operation that should be considered suspicious from a security perspective, such as tampering with a session cookie. Subclasses of *SuspiciousOperation* include:

- *DisallowedHost*
- *DisallowedModelAdminLookup*
- *DisallowedModelAdminToField*
- *DisallowedRedirect*
- *InvalidSessionKey*
- *RequestDataTooBig*
- *SuspiciousFileOperation*
- *SuspiciousMultipartForm*
- *SuspiciousSession*
- *TooManyFieldsSent*

If a *SuspiciousOperation* exception reaches the WSGI handler level it is logged at the `ERROR` level and results in a *HttpResponseBadRequest*. See the *logging documentation* for more information.

## PermissionDenied

### exception PermissionDenied

The *PermissionDenied* exception is raised when a user does not have permission to perform the action requested.

## ViewDoesNotExist

### exception ViewDoesNotExist

The *ViewDoesNotExist* exception is raised by *django.urls* when a requested view does not exist.

## MiddlewareNotUsed

### exception MiddlewareNotUsed

The *MiddlewareNotUsed* exception is raised when a middleware is not used in the server configuration.

## ImproperlyConfigured

### exception ImproperlyConfigured

The *ImproperlyConfigured* exception is raised when Django is somehow improperly configured – for example, if a value in `settings.py` is incorrect or unparseable.

## FieldError

### exception FieldError

The *FieldError* exception is raised when there is a problem with a model field. This can happen for several reasons:

- A field in a model clashes with a field of the same name from an abstract base class
- An infinite loop is caused by ordering
- A keyword cannot be parsed from the filter parameters
- A field cannot be determined from a keyword in the query parameters
- A join is not permitted on the specified field
- A field name is invalid
- A query contains invalid `order_by` arguments

## ValidationError

### exception ValidationError

The *ValidationError* exception is raised when data fails form or model field validation. For more information about validation, see *Form and Field Validation*, *Model Field Validation* and the *Validator Reference*.

## NON\_FIELD\_ERRORS

### NON\_FIELD\_ERRORS

*ValidationErrors* that don't belong to a particular field in a form or model are classified as `NON_FIELD_ERRORS`. This constant is used as a key in dictionaries that otherwise map fields to their respective list of errors.

## 6.10.2 URL Resolver exceptions

URL Resolver exceptions are defined in `django.urls`.

Deprecated since version 1.10: In older versions, these exceptions are located in `django.core.urlresolvers`. Importing from the old location will continue to work until Django 2.0.

### Resolver404

#### exception Resolver404

The *Resolver404* exception is raised by `resolve()` if the path passed to `resolve()` doesn't map to a view. It's a subclass of `django.http.Http404`.

### NoReverseMatch

#### exception NoReverseMatch

The *NoReverseMatch* exception is raised by `django.urls` when a matching URL in your URLconf cannot be identified based on the parameters supplied.

### 6.10.3 Database Exceptions

Database exceptions may be imported from `django.db`.

Django wraps the standard database exceptions so that your Django code has a guaranteed common implementation of these classes.

**exception** `Error`

**exception** `InterfaceError`

**exception** `DatabaseError`

**exception** `DataError`

**exception** `OperationalError`

**exception** `IntegrityError`

**exception** `InternalError`

**exception** `ProgrammingError`

**exception** `NotSupportedError`

The Django wrappers for database exceptions behave exactly the same as the underlying database exceptions. See [PEP 249](#), the Python Database API Specification v2.0, for further information.

As per [PEP 3134](#), a `__cause__` attribute is set with the original (underlying) database exception, allowing access to any additional information provided. (Note that this attribute is available under both Python 2 and Python 3, although [PEP 3134](#) normally only applies to Python 3. To avoid unexpected differences with Python 3, Django will also ensure that the exception made available via `__cause__` has a usable `__traceback__` attribute.)

The `__traceback__` attribute described above was added.

**exception** `models.ProtectedError`

Raised to prevent deletion of referenced objects when using `django.db.models.PROTECT`. `models.ProtectedError` is a subclass of `IntegrityError`.

### 6.10.4 Http Exceptions

Http exceptions may be imported from `django.http`.

**exception** `UnreadablePostError`

**exception** `UnreadablePostError`

`UnreadablePostError` is raised when a user cancels an upload.

### 6.10.5 Transaction Exceptions

Transaction exceptions are defined in `django.db.transaction`.

**exception** `TransactionManagementError`

**exception** `TransactionManagementError`

`TransactionManagementError` is raised for any and all problems related to database transactions.

## 6.10.6 Testing Framework Exceptions

Exceptions provided by the `django.test` package.

### `RedirectCycleError`

**exception** `client.RedirectCycleError`

`RedirectCycleError` is raised when the test client detects a loop or an overly long chain of redirects.

## 6.10.7 Python Exceptions

Django raises built-in Python exceptions when appropriate as well. See the Python documentation for further information on the [Built-in Exceptions](#).

# 6.11 File handling

## 6.11.1 The `File` object

The `django.core.files` module and its submodules contain built-in classes for basic file handling in Django.

### The `File` class

**class** `File` (*file\_object*)

The `File` class is a thin wrapper around a Python `file object` with some Django-specific additions. Internally, Django uses this class when it needs to represent a file.

`File` objects have the following attributes and methods:

**name**

The name of the file including the relative path from `MEDIA_ROOT`.

**size**

The size of the file in bytes.

**file**

The underlying `file object` that this class wraps.

---

**Be careful with this attribute in subclasses.**

Some subclasses of `File`, including `ContentFile` and `FieldFile`, may replace this attribute with an object other than a Python `file object`. In these cases, this attribute may itself be a `File` subclass (and not necessarily the same subclass). Whenever possible, use the attributes and methods of the subclass itself rather than the those of the subclass's `file` attribute.

---

**mode**

The read/write mode for the file.

**open** (*mode=None*)

Open or reopen the file (which also does `File.seek(0)`). The `mode` argument allows the same values as Python's built-in `open()`.

When reopening a file, `mode` will override whatever mode the file was originally opened with; `None` means to reopen with the original mode.

**read** (*num\_bytes=None*)

Read content from the file. The optional `size` is the number of bytes to read; if not specified, the file will be read to the end.

**\_\_iter\_\_** ()

Iterate over the file yielding one line at a time.

**chunks** (*chunk\_size=None*)

Iterate over the file yielding “chunks” of a given size. `chunk_size` defaults to 64 KB.

This is especially useful with very large files since it allows them to be streamed off disk and avoids storing the whole file in memory.

**multiple\_chunks** (*chunk\_size=None*)

Returns `True` if the file is large enough to require multiple chunks to access all of its content give some `chunk_size`.

**write** (*content*)

Writes the specified content string to the file. Depending on the storage system behind the scenes, this content might not be fully committed until `close()` is called on the file.

**close** ()

Close the file.

In addition to the listed methods, `File` exposes the following attributes and methods of its file object: `encoding`, `fileno`, `flush`, `isatty`, `newlines`, `read`, `readinto`, `readlines`, `seek`, `softspace`, `tell`, `truncate`, `writelines`, `xreadlines`. If you are using Python 3, the `seekable` method is also available.

The `seekable` method was added.

## The `ContentFile` class

**class** `ContentFile` (*File*)

The `ContentFile` class inherits from `File`, but unlike `File` it operates on string content (bytes also supported), rather than an actual file. For example:

```
from __future__ import unicode_literals
from django.core.files.base import ContentFile

f1 = ContentFile("esta sentencia está en español")
f2 = ContentFile(b"these are bytes")
```

## The `ImageFile` class

**class** `ImageFile` (*file\_object*)

Django provides a built-in class specifically for images. `django.core.files.images.ImageFile` inherits all the attributes and methods of `File`, and additionally provides the following:

**width**

Width of the image in pixels.

**height**

Height of the image in pixels.

## Additional methods on files attached to objects

Any *File* that is associated with an object (as with `Car.photo`, below) will also have a couple of extra methods:

`File.save` (*name*, *content*, *save=True*)

Saves a new file with the file name and contents provided. This will not replace the existing file, but will create a new file and update the object to point to it. If `save` is `True`, the model's `save()` method will be called once the file is saved. That is, these two lines:

```
>>> car.photo.save('myphoto.jpg', content, save=False)
>>> car.save()
```

are equivalent to:

```
>>> car.photo.save('myphoto.jpg', content, save=True)
```

Note that the `content` argument must be an instance of either *File* or of a subclass of *File*, such as *ContentFile*.

`File.delete` (*save=True*)

Removes the file from the model instance and deletes the underlying file. If `save` is `True`, the model's `save()` method will be called once the file is deleted.

## 6.11.2 File storage API

### Getting the current storage class

Django provides two convenient ways to access the current storage class:

**class** `DefaultStorage`

`DefaultStorage` provides lazy access to the current default storage system as defined by `DEFAULT_FILE_STORAGE`. `DefaultStorage` uses `get_storage_class()` internally.

**get\_storage\_class** (*import\_path=None*)

Returns a class or module which implements the storage API.

When called without the `import_path` parameter `get_storage_class` will return the current default storage system as defined by `DEFAULT_FILE_STORAGE`. If `import_path` is provided, `get_storage_class` will attempt to import the class or module from the given path and will return it if successful. An exception will be raised if the import is unsuccessful.

### The `FileSystemStorage` class

**class** `FileSystemStorage` (*location=None*, *base\_url=None*, *file\_permissions\_mode=None*, *directory\_permissions\_mode=None*)

The `FileSystemStorage` class implements basic file storage on a local filesystem. It inherits from `Storage` and provides implementations for all the public methods thereof.

**location**

Absolute path to the directory that will hold the files. Defaults to the value of your `MEDIA_ROOT` setting.

**base\_url**

URL that serves the files stored at this location. Defaults to the value of your `MEDIA_URL` setting.

**file\_permissions\_mode**

The file system permissions that the file will receive when it is saved. Defaults to `FILE_UPLOAD_PERMISSIONS`.

**directory\_permissions\_mode**

The file system permissions that the directory will receive when it is saved. Defaults to `FILE_UPLOAD_DIRECTORY_PERMISSIONS`.

---

**Note:** The `FileSystemStorage.delete()` method will not raise an exception if the given file name does not exist.

---

## The Storage class

### class Storage

The `Storage` class provides a standardized API for storing files, along with a set of default behaviors that all other storage systems can inherit or override as necessary.

---

**Note:** When methods return naive `datetime` objects, the effective timezone used will be the current value of `os.environ['TZ']`; note that this is usually set from Django's `TIME_ZONE`.

---

**accessed\_time** (*name*)

Returns a naive `datetime` object containing the last accessed time of the file. For storage systems that aren't able to return the last accessed time this will raise `NotImplementedError` instead.

Deprecated since version 1.10: Use `get_accessed_time()` instead.

**created\_time** (*name*)

Returns a naive `datetime` object containing the creation time of the file. For storage systems that aren't able to return the creation time this will raise `NotImplementedError` instead.

Deprecated since version 1.10: Use `get_created_time()` instead.

**delete** (*name*)

Deletes the file referenced by *name*. If deletion is not supported on the target storage system this will raise `NotImplementedError` instead

**exists** (*name*)

Returns `True` if a file referenced by the given name already exists in the storage system, or `False` if the name is available for a new file.

**get\_accessed\_time** (*name*)

Returns a `datetime` of the last accessed time of the file. For storage systems unable to return the last accessed time this will raise `NotImplementedError`.

If `USE_TZ` is `True`, returns an aware `datetime`, otherwise returns a naive `datetime` in the local timezone.

**get\_available\_name** (*name*, *max\_length=None*)

Returns a filename based on the *name* parameter that's free and available for new content to be written to on the target storage system.

The length of the filename will not exceed *max\_length*, if provided. If a free unique filename cannot be found, a `SuspiciousFileOperation` exception will be raised.

If a file with *name* already exists, an underscore plus a random 7 character alphanumeric string is appended to the filename before the extension.

**get\_created\_time** (*name*)

Returns a `datetime` of the creation time of the file. For storage systems unable to return the creation time this will raise `NotImplementedError`.

If `USE_TZ` is `True`, returns an aware `datetime`, otherwise returns a naive `datetime` in the local timezone.

**get\_modified\_time** (*name*)

Returns a `datetime` of the last modified time of the file. For storage systems unable to return the last modified time this will raise `NotImplementedError`.

If `USE_TZ` is `True`, returns an aware `datetime`, otherwise returns a naive `datetime` in the local timezone.

**get\_valid\_name** (*name*)

Returns a filename based on the `name` parameter that's suitable for use on the target storage system.

**generate\_filename** (*filename*)

Validates the `filename` by calling `get_valid_name()` and returns a filename to be passed to the `save()` method.

The `filename` argument may include a path as returned by `FileField.upload_to`. In that case, the path won't be passed to `get_valid_name()` but will be prepended back to the resulting name.

The default implementation uses `os.path` operations. Override this method if that's not appropriate for your storage.

**listdir** (*path*)

Lists the contents of the specified path, returning a 2-tuple of lists; the first item being directories, the second item being files. For storage systems that aren't able to provide such a listing, this will raise a `NotImplementedError` instead.

**modified\_time** (*name*)

Returns a naive `datetime` object containing the last modified time. For storage systems that aren't able to return the last modified time, this will raise `NotImplementedError` instead.

Deprecated since version 1.10: Use `get_modified_time()` instead.

**open** (*name*, *mode*='rb')

Opens the file given by `name`. Note that although the returned file is guaranteed to be a `File` object, it might actually be some subclass. In the case of remote file storage this means that reading/writing could be quite slow, so be warned.

**path** (*name*)

The local filesystem path where the file can be opened using Python's standard `open()`. For storage systems that aren't accessible from the local filesystem, this will raise `NotImplementedError` instead.

**save** (*name*, *content*, *max\_length*=None)

Saves a new file using the storage system, preferably with the name specified. If there already exists a file with this name `name`, the storage system may modify the filename as necessary to get a unique name. The actual name of the stored file will be returned.

The `max_length` argument is passed along to `get_available_name()`.

The `content` argument must be an instance of `django.core.files.File` or a file-like object that can be wrapped in `File`.

**size** (*name*)

Returns the total size, in bytes, of the file referenced by `name`. For storage systems that aren't able to return the file size this will raise `NotImplementedError` instead.

**url** (*name*)

Returns the URL where the contents of the file referenced by `name` can be accessed. For storage systems that don't support access by URL this will raise `NotImplementedError` instead.

### 6.11.3 Uploaded Files and Upload Handlers

#### Uploaded files

##### class `UploadedFile`

During file uploads, the actual file data is stored in `request.FILES`. Each entry in this dictionary is an `UploadedFile` object (or a subclass) – a simple wrapper around an uploaded file. You’ll usually use one of these methods to access the uploaded content:

##### `UploadedFile.read()`

Read the entire uploaded data from the file. Be careful with this method: if the uploaded file is huge it can overwhelm your system if you try to read it into memory. You’ll probably want to use `chunks()` instead; see below.

##### `UploadedFile.multiple_chunks(chunk_size=None)`

Returns `True` if the uploaded file is big enough to require reading in multiple chunks. By default this will be any file larger than 2.5 megabytes, but that’s configurable; see below.

##### `UploadedFile.chunks(chunk_size=None)`

A generator returning chunks of the file. If `multiple_chunks()` is `True`, you should use this method in a loop instead of `read()`.

In practice, it’s often easiest simply to use `chunks()` all the time. Looping over `chunks()` instead of using `read()` ensures that large files don’t overwhelm your system’s memory.

Here are some useful attributes of `UploadedFile`:

##### `UploadedFile.name`

The name of the uploaded file (e.g. `my_file.txt`).

##### `UploadedFile.size`

The size, in bytes, of the uploaded file.

##### `UploadedFile.content_type`

The content-type header uploaded with the file (e.g. `text/plain` or `application/pdf`). Like any data supplied by the user, you shouldn’t trust that the uploaded file is actually this type. You’ll still need to validate that the file contains the content that the content-type header claims – “trust but verify.”

##### `UploadedFile.content_type_extra`

A dictionary containing extra parameters passed to the `content-type` header. This is typically provided by services, such as Google App Engine, that intercept and handle file uploads on your behalf. As a result your handler may not receive the uploaded file content, but instead a URL or other pointer to the file. (see [RFC 2388](#) section 5.3).

##### `UploadedFile.charset`

For `text/*` content-types, the character set (i.e. `utf8`) supplied by the browser. Again, “trust but verify” is the best policy here.

---

**Note:** Like regular Python files, you can read the file line-by-line simply by iterating over the uploaded file:

```
for line in uploadedfile:
    do_something_with(line)
```

Lines are split using [universal newlines](#). The following are recognized as ending a line: the Unix end-of-line convention `'\n'`, the Windows convention `'\r\n'`, and the old Macintosh convention `'\r'`.

---

Subclasses of `UploadedFile` include:

**class TemporaryUploadedFile**

A file uploaded to a temporary location (i.e. stream-to-disk). This class is used by the *TemporaryFileUploadHandler*. In addition to the methods from *UploadedFile*, it has one additional method:

```
TemporaryUploadedFile.temporary_file_path()
```

Returns the full path to the temporary uploaded file.

**class InMemoryUploadedFile**

A file uploaded into memory (i.e. stream-to-memory). This class is used by the *MemoryFileUploadHandler*.

## Built-in upload handlers

Together the *MemoryFileUploadHandler* and *TemporaryFileUploadHandler* provide Django's default file upload behavior of reading small files into memory and large ones onto disk. They are located in `django.core.files.uploadhandler`.

**class MemoryFileUploadHandler**

File upload handler to stream uploads into memory (used for small files).

**class TemporaryFileUploadHandler**

Upload handler that streams data into a temporary file using *TemporaryUploadedFile*.

## Writing custom upload handlers

**class FileUploadHandler**

All file upload handlers should be subclasses of `django.core.files.uploadhandler.FileUploadHandler`. You can define upload handlers wherever you wish.

## Required methods

Custom file upload handlers **must** define the following methods:

```
FileUploadHandler.receive_data_chunk(raw_data, start)
```

Receives a “chunk” of data from the file upload.

`raw_data` is a byte string containing the uploaded data.

`start` is the position in the file where this `raw_data` chunk begins.

The data you return will get fed into the subsequent upload handlers' `receive_data_chunk` methods. In this way, one handler can be a “filter” for other handlers.

Return `None` from `receive_data_chunk` to short-circuit remaining upload handlers from getting this chunk. This is useful if you're storing the uploaded data yourself and don't want future handlers to store a copy of the data.

If you raise a `StopUpload` or a `SkipFile` exception, the upload will abort or the file will be completely skipped.

```
FileUploadHandler.file_complete(file_size)
```

Called when a file has finished uploading.

The handler should return an `UploadedFile` object that will be stored in `request.FILES`. Handlers may also return `None` to indicate that the `UploadedFile` object should come from subsequent upload handlers.

## Optional methods

Custom upload handlers may also define any of the following optional methods or attributes:

`FileUploadHandler.chunk_size`

Size, in bytes, of the “chunks” Django should store into memory and feed into the handler. That is, this attribute controls the size of chunks fed into `FileUploadHandler.receive_data_chunk`.

For maximum performance the chunk sizes should be divisible by 4 and should not exceed 2 GB ( $2^{31}$  bytes) in size. When there are multiple chunk sizes provided by multiple handlers, Django will use the smallest chunk size defined by any handler.

The default is  $64 \times 2^{10}$  bytes, or 64 KB.

`FileUploadHandler.new_file` (*field\_name*, *file\_name*, *content\_type*, *content\_length*, *charset*, *content\_type\_extra*)

Callback signaling that a new file upload is starting. This is called before any data has been fed to any upload handlers.

*field\_name* is a string name of the file `<input>` field.

*file\_name* is the unicode filename that was provided by the browser.

*content\_type* is the MIME type provided by the browser – E.g. `'image/jpeg'`.

*content\_length* is the length of the image given by the browser. Sometimes this won't be provided and will be `None`.

*charset* is the character set (i.e. `utf8`) given by the browser. Like *content\_length*, this sometimes won't be provided.

*content\_type\_extra* is extra information about the file from the *content-type* header. See `UploadedFile.content_type_extra`.

This method may raise a `StopFutureHandlers` exception to prevent future handlers from handling this file.

`FileUploadHandler.upload_complete()`

Callback signaling that the entire upload (all files) has completed.

`FileUploadHandler.handle_raw_input` (*input\_data*, *META*, *content\_length*, *boundary*, *encoding*)

Allows the handler to completely override the parsing of the raw HTTP input.

*input\_data* is a file-like object that supports `read()`-ing.

*META* is the same object as `request.META`.

*content\_length* is the length of the data in *input\_data*. Don't read more than *content\_length* bytes from *input\_data*.

*boundary* is the MIME boundary for this request.

*encoding* is the encoding of the request.

Return `None` if you want upload handling to continue, or a tuple of `(POST, FILES)` if you want to return the new data structures suitable for the request directly.

## 6.12 Forms

Detailed form API reference. For introductory material, see the *Working with forms* topic guide.

## 6.12.1 The Forms API

### About this document

This document covers the gritty details of Django’s forms API. You should read the *introduction to working with forms* first.

### Bound and unbound forms

A *Form* instance is either **bound** to a set of data, or **unbound**.

- If it’s **bound** to a set of data, it’s capable of validating that data and rendering the form as HTML with the data displayed in the HTML.
- If it’s **unbound**, it cannot do validation (because there’s no data to validate!), but it can still render the blank form as HTML.

#### class `Form`

To create an unbound *Form* instance, simply instantiate the class:

```
>>> f = ContactForm()
```

To bind data to a form, pass the data as a dictionary as the first parameter to your *Form* class constructor:

```
>>> data = {'subject': 'hello',
...         'message': 'Hi there',
...         'sender': 'foo@example.com',
...         'cc_myself': True}
>>> f = ContactForm(data)
```

In this dictionary, the keys are the field names, which correspond to the attributes in your *Form* class. The values are the data you’re trying to validate. These will usually be strings, but there’s no requirement that they be strings; the type of data you pass depends on the *Field*, as we’ll see in a moment.

#### `Form.is_bound`

If you need to distinguish between bound and unbound form instances at runtime, check the value of the form’s *is\_bound* attribute:

```
>>> f = ContactForm()
>>> f.is_bound
False
>>> f = ContactForm({'subject': 'hello'})
>>> f.is_bound
True
```

Note that passing an empty dictionary creates a *bound* form with empty data:

```
>>> f = ContactForm({})
>>> f.is_bound
True
```

If you have a bound *Form* instance and want to change the data somehow, or if you want to bind an unbound *Form* instance to some data, create another *Form* instance. There is no way to change data in a *Form* instance. Once a *Form* instance has been created, you should consider its data immutable, whether it has data or not.

## Using forms to validate data

Form.**clean**()

Implement a `clean()` method on your `Form` when you must add custom validation for fields that are interdependent. See *Cleaning and validating fields that depend on each other* for example usage.

Form.**is\_valid**()

The primary task of a `Form` object is to validate data. With a bound `Form` instance, call the `is_valid()` method to run validation and return a boolean designating whether the data was valid:

```
>>> data = {'subject': 'hello',
...         'message': 'Hi there',
...         'sender': 'foo@example.com',
...         'cc_myself': True}
>>> f = ContactForm(data)
>>> f.is_valid()
True
```

Let's try with some invalid data. In this case, `subject` is blank (an error, because all fields are required by default) and `sender` is not a valid email address:

```
>>> data = {'subject': '',
...         'message': 'Hi there',
...         'sender': 'invalid email address',
...         'cc_myself': True}
>>> f = ContactForm(data)
>>> f.is_valid()
False
```

Form.**errors**

Access the `errors` attribute to get a dictionary of error messages:

```
>>> f.errors
{'sender': ['Enter a valid email address.'], 'subject': ['This field is required.']}
```

In this dictionary, the keys are the field names, and the values are lists of Unicode strings representing the error messages. The error messages are stored in lists because a field can have multiple error messages.

You can access `errors` without having to call `is_valid()` first. The form's data will be validated the first time either you call `is_valid()` or access `errors`.

The validation routines will only get called once, regardless of how many times you access `errors` or call `is_valid()`. This means that if validation has side effects, those side effects will only be triggered once.

Form.errors.**as\_data**()

Returns a dict that maps fields to their original `ValidationError` instances.

```
>>> f.errors.as_data()
{'sender': [ValidationError(['Enter a valid email address.'])],
'subject': [ValidationError(['This field is required.'])]}
```

Use this method anytime you need to identify an error by its `code`. This enables things like rewriting the error's message or writing custom logic in a view when a given error is present. It can also be used to serialize the errors in a custom format (e.g. XML); for instance, `as_json()` relies on `as_data()`.

The need for the `as_data()` method is due to backwards compatibility. Previously `ValidationError` instances were lost as soon as their **rendered** error messages were added to the `Form.errors` dictionary. Ideally `Form`.

errors would have stored `ValidationError` instances and methods with an `as_` prefix could render them, but it had to be done the other way around in order not to break code that expects rendered error messages in `Form.errors`.

`Form.errors.as_json(escape_html=False)`

Returns the errors serialized as JSON.

```
>>> f.errors.as_json()
{"sender": [{"message": "Enter a valid email address.", "code": "invalid"}],
"subject": [{"message": "This field is required.", "code": "required"}]}
```

By default, `as_json()` does not escape its output. If you are using it for something like AJAX requests to a form view where the client interprets the response and inserts errors into the page, you'll want to be sure to escape the results on the client-side to avoid the possibility of a cross-site scripting attack. It's trivial to do so using a JavaScript library like jQuery - simply use `$(el).text(errorText)` rather than `.html()`.

If for some reason you don't want to use client-side escaping, you can also set `escape_html=True` and error messages will be escaped so you can use them directly in HTML.

`Form.add_error(field, error)`

This method allows adding errors to specific fields from within the `Form.clean()` method, or from outside the form altogether; for instance from a view.

The `field` argument is the name of the field to which the errors should be added. If its value is `None` the error will be treated as a non-field error as returned by `Form.non_field_errors()`.

The `error` argument can be a simple string, or preferably an instance of `ValidationError`. See [Raising ValidationError](#) for best practices when defining form errors.

Note that `Form.add_error()` automatically removes the relevant field from `cleaned_data`.

`Form.has_error(field, code=None)`

This method returns a boolean designating whether a field has an error with a specific error code. If `code` is `None`, it will return `True` if the field contains any errors at all.

To check for non-field errors use `NON_FIELD_ERRORS` as the `field` parameter.

`Form.non_field_errors()`

This method returns the list of errors from `Form.errors` that aren't associated with a particular field. This includes `ValidationErrors` that are raised in `Form.clean()` and errors added using `Form.add_error(None, "...")`.

## Behavior of unbound forms

It's meaningless to validate a form with no data, but, for the record, here's what happens with unbound forms:

```
>>> f = ContactForm()
>>> f.is_valid()
False
>>> f.errors
{}
```

## Dynamic initial values

`Form.initial`

Use *initial* to declare the initial value of form fields at runtime. For example, you might want to fill in a username field with the username of the current session.

To accomplish this, use the *initial* argument to a *Form*. This argument, if given, should be a dictionary mapping field names to initial values. Only include the fields for which you're specifying an initial value; it's not necessary to include every field in your form. For example:

```
>>> f = ContactForm(initial={'subject': 'Hi there!'})
```

These values are only displayed for unbound forms, and they're not used as fallback values if a particular value isn't provided.

If a *Field* defines *initial* and you include *initial* when instantiating the Form, then the latter *initial* will have precedence. In this example, *initial* is provided both at the field level and at the form instance level, and the latter gets precedence:

```
>>> from django import forms
>>> class CommentForm(forms.Form):
...     name = forms.CharField(initial='class')
...     url = forms.URLField()
...     comment = forms.CharField()
>>> f = CommentForm(initial={'name': 'instance'}, auto_id=False)
>>> print(f)
<tr><th>Name:</th><td><input type="text" name="name" value="instance" required /></td>
↪</tr>
<tr><th>Url:</th><td><input type="url" name="url" required /></td></tr>
<tr><th>Comment:</th><td><input type="text" name="comment" required /></td></tr>
```

## Checking which form data has changed

Form.**has\_changed()**

Use the *has\_changed()* method on your Form when you need to check if the form data has been changed from the initial data.

```
>>> data = {'subject': 'hello',
...        'message': 'Hi there',
...        'sender': 'foo@example.com',
...        'cc_myself': True}
>>> f = ContactForm(data, initial=data)
>>> f.has_changed()
False
```

When the form is submitted, we reconstruct it and provide the original data so that the comparison can be done:

```
>>> f = ContactForm(request.POST, initial=data)
>>> f.has_changed()
```

*has\_changed()* will be *True* if the data from *request.POST* differs from what was provided in *initial* or *False* otherwise. The result is computed by calling *Field.has\_changed()* for each field in the form.

Form.**changed\_data**

The *changed\_data* attribute returns a list of the names of the fields whose values in the form's bound data (usually *request.POST*) differ from what was provided in *initial*. It returns an empty list if no data differs.

```
>>> f = ContactForm(request.POST, initial=data)
>>> if f.has_changed():
...     print("The following fields changed: %s" % ", ".join(f.changed_data))
```

## Accessing the fields from the form

### Form.fields

You can access the fields of *Form* instance from its `fields` attribute:

```
>>> for row in f.fields.values(): print(row)
...
<django.forms.fields.CharField object at 0x7ffaac632510>
<django.forms.fields.URLField object at 0x7ffaac632f90>
<django.forms.fields.CharField object at 0x7ffaac3aa050>
>>> f.fields['name']
<django.forms.fields.CharField object at 0x7ffaac6324d0>
```

You can alter the field of *Form* instance to change the way it is presented in the form:

```
>>> f.as_table().split('\n')[0]
'<tr><th>Name:</th><td><input name="name" type="text" value="instance" required /></td></tr>'
↳<td></tr>'
>>> f.fields['name'].label = "Username"
>>> f.as_table().split('\n')[0]
'<tr><th>Username:</th><td><input name="name" type="text" value="instance" required /></td></tr>'
↳</td></tr>'
```

Beware not to alter the `base_fields` attribute because this modification will influence all subsequent *ContactForm* instances within the same Python process:

```
>>> f.base_fields['name'].label = "Username"
>>> another_f = CommentForm(auto_id=False)
>>> another_f.as_table().split('\n')[0]
'<tr><th>Username:</th><td><input name="name" type="text" value="class" required /></td></tr>'
↳<td></tr>'
```

## Accessing “clean” data

### Form.cleaned\_data

Each field in a *Form* class is responsible not only for validating data, but also for “cleaning” it – normalizing it to a consistent format. This is a nice feature, because it allows data for a particular field to be input in a variety of ways, always resulting in consistent output.

For example, *DateField* normalizes input into a Python `datetime.date` object. Regardless of whether you pass it a string in the format `'1994-07-15'`, a `datetime.date` object, or a number of other formats, *DateField* will always normalize it to a `datetime.date` object as long as it’s valid.

Once you’ve created a *Form* instance with a set of data and validated it, you can access the clean data via its `cleaned_data` attribute:

```
>>> data = {'subject': 'hello',
...        'message': 'Hi there',
...        'sender': 'foo@example.com',
...        'cc_myself': True}
```

```
>>> f = ContactForm(data)
>>> f.is_valid()
True
>>> f.cleaned_data
{'cc_myself': True, 'message': 'Hi there', 'sender': 'foo@example.com', 'subject':
↪ 'hello'}
```

Note that any text-based field – such as CharField or EmailField – always cleans the input into a Unicode string. We’ll cover the encoding implications later in this document.

If your data does *not* validate, the `cleaned_data` dictionary contains only the valid fields:

```
>>> data = {'subject': '',
...         'message': 'Hi there',
...         'sender': 'invalid email address',
...         'cc_myself': True}
>>> f = ContactForm(data)
>>> f.is_valid()
False
>>> f.cleaned_data
{'cc_myself': True, 'message': 'Hi there'}
```

`cleaned_data` will always *only* contain a key for fields defined in the Form, even if you pass extra data when you define the Form. In this example, we pass a bunch of extra fields to the `ContactForm` constructor, but `cleaned_data` contains only the form’s fields:

```
>>> data = {'subject': 'hello',
...         'message': 'Hi there',
...         'sender': 'foo@example.com',
...         'cc_myself': True,
...         'extra_field_1': 'foo',
...         'extra_field_2': 'bar',
...         'extra_field_3': 'baz'}
>>> f = ContactForm(data)
>>> f.is_valid()
True
>>> f.cleaned_data # Doesn't contain extra_field_1, etc.
{'cc_myself': True, 'message': 'Hi there', 'sender': 'foo@example.com', 'subject':
↪ 'hello'}
```

When the Form is valid, `cleaned_data` will include a key and value for *all* its fields, even if the data didn’t include a value for some optional fields. In this example, the data dictionary doesn’t include a value for the `nick_name` field, but `cleaned_data` includes it, with an empty value:

```
>>> from django import forms
>>> class OptionalPersonForm(forms.Form):
...     first_name = forms.CharField()
...     last_name = forms.CharField()
...     nick_name = forms.CharField(required=False)
>>> data = {'first_name': 'John', 'last_name': 'Lennon'}
>>> f = OptionalPersonForm(data)
>>> f.is_valid()
True
>>> f.cleaned_data
{'nick_name': '', 'first_name': 'John', 'last_name': 'Lennon'}
```

In this above example, the `cleaned_data` value for `nick_name` is set to an empty string, because `nick_name` is CharField, and CharFields treat empty values as an empty string. Each field type knows what its “blank” value

is – e.g., for `DateField`, it's `None` instead of the empty string. For full details on each field's behavior in this case, see the “Empty value” note for each field in the “Built-in Field classes” section below.

You can write code to perform validation for particular form fields (based on their name) or for the form as a whole (considering combinations of various fields). More information about this is in [Form and field validation](#).

## Outputting forms as HTML

The second task of a `Form` object is to render itself as HTML. To do so, simply print it:

```
>>> f = ContactForm()
>>> print(f)
<tr><th><label for="id_subject">Subject:</label></th><td><input id="id_subject" type=
↪ "text" name="subject" maxlength="100" required /></td></tr>
<tr><th><label for="id_message">Message:</label></th><td><input type="text" name=
↪ "message" id="id_message" required /></td></tr>
<tr><th><label for="id_sender">Sender:</label></th><td><input type="email" name=
↪ "sender" id="id_sender" required /></td></tr>
<tr><th><label for="id_cc_myself">Cc myself:</label></th><td><input type="checkbox"
↪ name="cc_myself" id="id_cc_myself" /></td></tr>
```

If the form is bound to data, the HTML output will include that data appropriately. For example, if a field is represented by an `<input type="text">`, the data will be in the `value` attribute. If a field is represented by an `<input type="checkbox">`, then that HTML will include `checked="checked"` if appropriate:

```
>>> data = {'subject': 'hello',
...         'message': 'Hi there',
...         'sender': 'foo@example.com',
...         'cc_myself': True}
>>> f = ContactForm(data)
>>> print(f)
<tr><th><label for="id_subject">Subject:</label></th><td><input id="id_subject" type=
↪ "text" name="subject" maxlength="100" value="hello" required /></td></tr>
<tr><th><label for="id_message">Message:</label></th><td><input type="text" name=
↪ "message" id="id_message" value="Hi there" required /></td></tr>
<tr><th><label for="id_sender">Sender:</label></th><td><input type="email" name=
↪ "sender" id="id_sender" value="foo@example.com" required /></td></tr>
<tr><th><label for="id_cc_myself">Cc myself:</label></th><td><input type="checkbox"
↪ name="cc_myself" id="id_cc_myself" checked="checked" /></td></tr>
```

This default output is a two-column HTML table, with a `<tr>` for each field. Notice the following:

- For flexibility, the output does *not* include the `<table>` and `</table>` tags, nor does it include the `<form>` and `</form>` tags or an `<input type="submit">` tag. It's your job to do that.
- Each field type has a default HTML representation. `CharField` is represented by an `<input type="text">` and `EmailField` by an `<input type="email">`. `BooleanField` is represented by an `<input type="checkbox">`. Note these are merely sensible defaults; you can specify which HTML to use for a given field by using widgets, which we'll explain shortly.
- The HTML name for each tag is taken directly from its attribute name in the `ContactForm` class.
- The text label for each field – e.g. `'Subject: '`, `'Message: '` and `'Cc myself: '` is generated from the field name by converting all underscores to spaces and upper-casing the first letter. Again, note these are merely sensible defaults; you can also specify labels manually.
- Each text label is surrounded in an HTML `<label>` tag, which points to the appropriate form field via its `id`. Its `id`, in turn, is generated by prepending `'id_'` to the field name. The `id` attributes and `<label>` tags are included in the output by default, to follow best practices, but you can change that behavior.

Although `<table>` output is the default output style when you `print` a form, other output styles are available. Each style is available as a method on a form object, and each rendering method returns a Unicode object.

### `as_p()`

Form.`as_p()`

`as_p()` renders the form as a series of `<p>` tags, with each `<p>` containing one field:

```
>>> f = ContactForm()
>>> f.as_p()
'<p><label for="id_subject">Subject:</label> <input id="id_subject" type="text" name=
↪ "subject" maxlength="100" required /></p>\n<p><label for="id_message">Message:</
↪ label> <input type="text" name="message" id="id_message" required /></p>\n<p><label
↪ for="id_sender">Sender:</label> <input type="text" name="sender" id="id_sender"
↪ required /></p>\n<p><label for="id_cc_myself">Cc myself:</label> <input type=
↪ "checkbox" name="cc_myself" id="id_cc_myself" /></p>'
>>> print(f.as_p())
<p><label for="id_subject">Subject:</label> <input id="id_subject" type="text" name=
↪ "subject" maxlength="100" required /></p>
<p><label for="id_message">Message:</label> <input type="text" name="message" id="id_
↪ message" required /></p>
<p><label for="id_sender">Sender:</label> <input type="email" name="sender" id="id_
↪ sender" required /></p>
<p><label for="id_cc_myself">Cc myself:</label> <input type="checkbox" name="cc_myself
↪ " id="id_cc_myself" /></p>
```

### `as_ul()`

Form.`as_ul()`

`as_ul()` renders the form as a series of `<li>` tags, with each `<li>` containing one field. It does *not* include the `<ul>` or `</ul>`, so that you can specify any HTML attributes on the `<ul>` for flexibility:

```
>>> f = ContactForm()
>>> f.as_ul()
'<li><label for="id_subject">Subject:</label> <input id="id_subject" type="text" name=
↪ "subject" maxlength="100" required /></li>\n<li><label for="id_message">Message:</
↪ label> <input type="text" name="message" id="id_message" required /></li>\n<li>
↪ <label for="id_sender">Sender:</label> <input type="email" name="sender" id="id_
↪ sender" required /></li>\n<li><label for="id_cc_myself">Cc myself:</label> <input
↪ type="checkbox" name="cc_myself" id="id_cc_myself" /></li>'
>>> print(f.as_ul())
<li><label for="id_subject">Subject:</label> <input id="id_subject" type="text" name=
↪ "subject" maxlength="100" required /></li>
<li><label for="id_message">Message:</label> <input type="text" name="message" id="id_
↪ message" required /></li>
<li><label for="id_sender">Sender:</label> <input type="email" name="sender" id="id_
↪ sender" required /></li>
<li><label for="id_cc_myself">Cc myself:</label> <input type="checkbox" name="cc_
↪ myself" id="id_cc_myself" /></li>
```

## as\_table()

Form.**as\_table**()

Finally, `as_table()` outputs the form as an HTML `<table>`. This is exactly the same as `print`. In fact, when you print a form object, it calls its `as_table()` method behind the scenes:

```
>>> f = ContactForm()
>>> f.as_table()
'<tr><th><label for="id_subject">Subject:</label></th><td><input id="id_subject" type=
↪ "text" name="subject" maxlength="100" required /></td></tr>\n<tr><th><label for="id_
↪ message">Message:</label></th><td><input type="text" name="message" id="id_message"
↪ required /></td></tr>\n<tr><th><label for="id_sender">Sender:</label></th><td>
↪ <input type="email" name="sender" id="id_sender" required /></td></tr>\n<tr><th>
↪ <label for="id_cc_myself">Cc myself:</label></th><td><input type="checkbox" name=
↪ "cc_myself" id="id_cc_myself" /></td></tr>'
>>> print(f)
<tr><th><label for="id_subject">Subject:</label></th><td><input id="id_subject" type=
↪ "text" name="subject" maxlength="100" required /></td></tr>
<tr><th><label for="id_message">Message:</label></th><td><input type="text" name=
↪ "message" id="id_message" required /></td></tr>
<tr><th><label for="id_sender">Sender:</label></th><td><input type="email" name=
↪ "sender" id="id_sender" required /></td></tr>
<tr><th><label for="id_cc_myself">Cc myself:</label></th><td><input type="checkbox"
↪ name="cc_myself" id="id_cc_myself" /></td></tr>
```

## Styling required or erroneous form rows

Form.**error\_css\_class**

Form.**required\_css\_class**

It's pretty common to style form rows and fields that are required or have errors. For example, you might want to present required form rows in bold and highlight errors in red.

The `Form` class has a couple of hooks you can use to add `class` attributes to required rows or to rows with errors: simply set the `Form.error_css_class` and/or `Form.required_css_class` attributes:

```
from django import forms

class ContactForm(forms.Form):
    error_css_class = 'error'
    required_css_class = 'required'

    # ... and the rest of your fields here
```

Once you've done that, rows will be given "error" and/or "required" classes, as needed. The HTML will look something like:

```
>>> f = ContactForm(data)
>>> print(f.as_table())
<tr class="required"><th><label class="required" for="id_subject">Subject:</label>
↪ ...
<tr class="required"><th><label class="required" for="id_message">Message:</label>
↪ ...
<tr class="required error"><th><label class="required" for="id_sender">Sender:</label>
↪ ...
```

```
<tr><th><label for="id_cc_myself">Cc myself:</label> ...
>>> f['subject'].label_tag()
<label class="required" for="id_subject">Subject:</label>
>>> f['subject'].label_tag(attrs={'class': 'foo'})
<label for="id_subject" class="foo required">Subject:</label>
```

## Configuring form elements' HTML id attributes and <label> tags

### Form.`auto_id`

By default, the form rendering methods include:

- HTML id attributes on the form elements.
- The corresponding <label> tags around the labels. An HTML <label> tag designates which label text is associated with which form element. This small enhancement makes forms more usable and more accessible to assistive devices. It's always a good idea to use <label> tags.

The id attribute values are generated by prepending `id_` to the form field names. This behavior is configurable, though, if you want to change the id convention or remove HTML id attributes and <label> tags entirely.

Use the `auto_id` argument to the `Form` constructor to control the id and label behavior. This argument must be `True`, `False` or a string.

If `auto_id` is `False`, then the form output will not include <label> tags nor id attributes:

```
>>> f = ContactForm(auto_id=False)
>>> print(f.as_table())
<tr><th>Subject:</th><td><input type="text" name="subject" maxlength="100" required />
↵</td></tr>
<tr><th>Message:</th><td><input type="text" name="message" required /></td></tr>
<tr><th>Sender:</th><td><input type="email" name="sender" required /></td></tr>
<tr><th>Cc myself:</th><td><input type="checkbox" name="cc_myself" /></td></tr>
>>> print(f.as_ul())
<li>Subject: <input type="text" name="subject" maxlength="100" required /></li>
<li>Message: <input type="text" name="message" required /></li>
<li>Sender: <input type="email" name="sender" required /></li>
<li>Cc myself: <input type="checkbox" name="cc_myself" /></li>
>>> print(f.as_p())
<p>Subject: <input type="text" name="subject" maxlength="100" required /></p>
<p>Message: <input type="text" name="message" required /></p>
<p>Sender: <input type="email" name="sender" required /></p>
<p>Cc myself: <input type="checkbox" name="cc_myself" /></p>
```

If `auto_id` is set to `True`, then the form output *will* include <label> tags and will simply use the field name as its id for each form field:

```
>>> f = ContactForm(auto_id=True)
>>> print(f.as_table())
<tr><th><label for="subject">Subject:</label></th><td><input id="subject" type="text"
↵name="subject" maxlength="100" required /></td></tr>
<tr><th><label for="message">Message:</label></th><td><input type="text" name="message
↵" id="message" required /></td></tr>
<tr><th><label for="sender">Sender:</label></th><td><input type="email" name="sender"
↵id="sender" required /></td></tr>
<tr><th><label for="cc_myself">Cc myself:</label></th><td><input type="checkbox" name=
↵"cc_myself" id="cc_myself" /></td></tr>
>>> print(f.as_ul())
```

```

<li><label for="subject">Subject:</label> <input id="subject" type="text" name=
↳ "subject" maxlength="100" required /></li>
<li><label for="message">Message:</label> <input type="text" name="message" id=
↳ "message" required /></li>
<li><label for="sender">Sender:</label> <input type="email" name="sender" id="sender"
↳ required /></li>
<li><label for="cc_myself">Cc myself:</label> <input type="checkbox" name="cc_myself"
↳ id="cc_myself" /></li>
>>> print(f.as_p())
<p><label for="subject">Subject:</label> <input id="subject" type="text" name="subject
↳ " maxlength="100" required /></p>
<p><label for="message">Message:</label> <input type="text" name="message" id="message
↳ " required /></p>
<p><label for="sender">Sender:</label> <input type="email" name="sender" id="sender"
↳ required /></p>
<p><label for="cc_myself">Cc myself:</label> <input type="checkbox" name="cc_myself"
↳ id="cc_myself" /></p>

```

If `auto_id` is set to a string containing the format character `'%s'`, then the form output will include `<label>` tags, and will generate `id` attributes based on the format string. For example, for a format string `'field_%s'`, a field named `subject` will get the `id` value `'field_subject'`. Continuing our example:

```

>>> f = ContactForm(auto_id='id_for_%s')
>>> print(f.as_table())
<tr><th><label for="id_for_subject">Subject:</label></th><td><input id="id_for_subject
↳ " type="text" name="subject" maxlength="100" required /></td></tr>
<tr><th><label for="id_for_message">Message:</label></th><td><input type="text" name=
↳ "message" id="id_for_message" required /></td></tr>
<tr><th><label for="id_for_sender">Sender:</label></th><td><input type="email" name=
↳ "sender" id="id_for_sender" required /></td></tr>
<tr><th><label for="id_for_cc_myself">Cc myself:</label></th><td><input type="checkbox"
↳ " name="cc_myself" id="id_for_cc_myself" /></td></tr>
>>> print(f.as_ul())
<li><label for="id_for_subject">Subject:</label> <input id="id_for_subject" type="text
↳ " name="subject" maxlength="100" required /></li>
<li><label for="id_for_message">Message:</label> <input type="text" name="message" id=
↳ "id_for_message" required /></li>
<li><label for="id_for_sender">Sender:</label> <input type="email" name="sender" id=
↳ "id_for_sender" required /></li>
<li><label for="id_for_cc_myself">Cc myself:</label> <input type="checkbox" name="cc_
↳ myself" id="id_for_cc_myself" /></li>
>>> print(f.as_p())
<p><label for="id_for_subject">Subject:</label> <input id="id_for_subject" type="text
↳ " name="subject" maxlength="100" required /></p>
<p><label for="id_for_message">Message:</label> <input type="text" name="message" id=
↳ "id_for_message" required /></p>
<p><label for="id_for_sender">Sender:</label> <input type="email" name="sender" id=
↳ "id_for_sender" required /></p>
<p><label for="id_for_cc_myself">Cc myself:</label> <input type="checkbox" name="cc_
↳ myself" id="id_for_cc_myself" /></p>

```

If `auto_id` is set to any other true value – such as a string that doesn't include `%s` – then the library will act as if `auto_id` is `True`.

By default, `auto_id` is set to the string `'id_%s'`.

#### Form.`label_suffix`

A translatable string (defaults to a colon (`:`) in English) that will be appended after any label name when a form is

rendered.

It's possible to customize that character, or omit it entirely, using the `label_suffix` parameter:

```
>>> f = ContactForm(auto_id='id_for_%s', label_suffix='')
>>> print(f.as_ul())
<li><label for="id_for_subject">Subject</label> <input id="id_for_subject" type="text"
↳ name="subject" maxlength="100" required /></li>
<li><label for="id_for_message">Message</label> <input type="text" name="message" id=
↳ "id_for_message" required /></li>
<li><label for="id_for_sender">Sender</label> <input type="email" name="sender" id=
↳ "id_for_sender" required /></li>
<li><label for="id_for_cc_myself">Cc myself</label> <input type="checkbox" name="cc_
↳ myself" id="id_for_cc_myself" /></li>
>>> f = ContactForm(auto_id='id_for_%s', label_suffix=' ->')
>>> print(f.as_ul())
<li><label for="id_for_subject">Subject -></label> <input id="id_for_subject" type=
↳ "text" name="subject" maxlength="100" required /></li>
<li><label for="id_for_message">Message -></label> <input type="text" name="message"
↳ id="id_for_message" required /></li>
<li><label for="id_for_sender">Sender -></label> <input type="email" name="sender" id=
↳ "id_for_sender" required /></li>
<li><label for="id_for_cc_myself">Cc myself -></label> <input type="checkbox" name=
↳ "cc_myself" id="id_for_cc_myself" /></li>
```

Note that the label suffix is added only if the last character of the label isn't a punctuation character (in English, those are `.`, `!`, `?` or `:`).

Fields can also define their own `label_suffix`. This will take precedence over `Form.label_suffix`. The suffix can also be overridden at runtime using the `label_suffix` parameter to `label_tag()`.

#### Form.`use_required_attribute`

When set to `True` (the default), required form fields will have the `required` HTML attribute.

`Formsets` instantiate forms with `use_required_attribute=False` to avoid incorrect browser validation when adding and deleting forms from a formset.

## Notes on field ordering

In the `as_p()`, `as_ul()` and `as_table()` shortcuts, the fields are displayed in the order in which you define them in your form class. For example, in the `ContactForm` example, the fields are defined in the order `subject`, `message`, `sender`, `cc_myself`. To reorder the HTML output, just change the order in which those fields are listed in the class.

There are several other ways to customize the order:

#### Form.`field_order`

By default `Form.field_order=None`, which retains the order in which you define the fields in your form class. If `field_order` is a list of field names, the fields are ordered as specified by the list and remaining fields are appended according to the default order. Unknown field names in the list are ignored. This makes it possible to disable a field in a subclass by setting it to `None` without having to redefine ordering.

You can also use the `Form.field_order` argument to a `Form` to override the field order. If a `Form` defines `field_order` and you include `field_order` when instantiating the `Form`, then the latter `field_order` will have precedence.

Form.`order_fields` (`field_order`)

You may rearrange the fields any time using `order_fields()` with a list of field names as in [field\\_order](#).

## How errors are displayed

If you render a bound `Form` object, the act of rendering will automatically run the form's validation if it hasn't already happened, and the HTML output will include the validation errors as a `<ul class="errorlist">` near the field. The particular positioning of the error messages depends on the output method you're using:

```
>>> data = {'subject': '',
...         'message': 'Hi there',
...         'sender': 'invalid email address',
...         'cc_myself': True}
>>> f = ContactForm(data, auto_id=False)
>>> print(f.as_table())
<tr><th>Subject:</th><td><ul class="errorlist"><li>This field is required.</li></ul>
↪<input type="text" name="subject" maxlength="100" required /></td></tr>
<tr><th>Message:</th><td><input type="text" name="message" value="Hi there" required /
↪</td></tr>
<tr><th>Sender:</th><td><ul class="errorlist"><li>Enter a valid email address.</li></
↪ul><input type="email" name="sender" value="invalid email address" required /></td>
↪</tr>
<tr><th>Cc myself:</th><td><input checked="checked" type="checkbox" name="cc_myself" /
↪</td></tr>
>>> print(f.as_ul())
<li><ul class="errorlist"><li>This field is required.</li></ul>Subject: <input type=
↪ "text" name="subject" maxlength="100" required /></li>
<li>Message: <input type="text" name="message" value="Hi there" required /></li>
<li><ul class="errorlist"><li>Enter a valid email address.</li></ul>Sender: <input
↪ type="email" name="sender" value="invalid email address" required /></li>
<li>Cc myself: <input checked="checked" type="checkbox" name="cc_myself" /></li>
>>> print(f.as_p())
<p><ul class="errorlist"><li>This field is required.</li></ul></p>
<p>Subject: <input type="text" name="subject" maxlength="100" required /></p>
<p>Message: <input type="text" name="message" value="Hi there" required /></p>
<p><ul class="errorlist"><li>Enter a valid email address.</li></ul></p>
<p>Sender: <input type="email" name="sender" value="invalid email address" required /
↪ </p>
<p>Cc myself: <input checked="checked" type="checkbox" name="cc_myself" /></p>
```

## Customizing the error list format

By default, forms use `django.forms.utils.ErrorList` to format validation errors. If you'd like to use an alternate class for displaying errors, you can pass that in at construction time (replace `__str__` by `__unicode__` on Python 2):

```
>>> from django.forms.utils import ErrorList
>>> class DivErrorList(ErrorList):
...     def __str__(self):
...         # __unicode__ on Python 2
...         return self.as_divs()
...     def as_divs(self):
...         if not self: return ''
...         return '<div class="errorlist">%s</div>' % ''.join(['<div class="error">%s
↪ </div>' % e for e in self])
>>> f = ContactForm(data, auto_id=False, error_class=DivErrorList)
>>> f.as_p()
```

```
<div class="errorlist"><div class="error">This field is required.</div></div>
<p>Subject: <input type="text" name="subject" maxlength="100" required /></p>
<p>Message: <input type="text" name="message" value="Hi there" required /></p>
<div class="errorlist"><div class="error">Enter a valid email address.</div></div>
<p>Sender: <input type="email" name="sender" value="invalid email address" required />
↵</p>
<p>Cc myself: <input checked="checked" type="checkbox" name="cc_myself" /></p>
```

## More granular output

The `as_p()`, `as_ul()`, and `as_table()` methods are simply shortcuts – they’re not the only way a form object can be displayed.

### class `BoundField`

Used to display HTML or access attributes for a single field of a `Form` instance.

The `__str__()` (`__unicode__` on Python 2) method of this object displays the HTML for this field.

To retrieve a single `BoundField`, use dictionary lookup syntax on your form using the field’s name as the key:

```
>>> form = ContactForm()
>>> print(form['subject'])
<input id="id_subject" type="text" name="subject" maxlength="100" required />
```

To retrieve all `BoundField` objects, iterate the form:

```
>>> form = ContactForm()
>>> for boundfield in form: print(boundfield)
<input id="id_subject" type="text" name="subject" maxlength="100" required />
<input type="text" name="message" id="id_message" required />
<input type="email" name="sender" id="id_sender" required />
<input type="checkbox" name="cc_myself" id="id_cc_myself" />
```

The field-specific output honors the form object’s `auto_id` setting:

```
>>> f = ContactForm(auto_id=False)
>>> print(f['message'])
<input type="text" name="message" required />
>>> f = ContactForm(auto_id='id_%s')
>>> print(f['message'])
<input type="text" name="message" id="id_message" required />
```

## Attributes of `BoundField`

### `BoundField.auto_id`

The HTML ID attribute for this `BoundField`. Returns an empty string if `Form.auto_id` is `False`.

### `BoundField.data`

This property returns the data for this `BoundField` extracted by the widget’s `value_from_datadict()` method, or `None` if it wasn’t given:

```
>>> unbound_form = ContactForm()
>>> print(unbound_form['subject'].data)
None
>>> bound_form = ContactForm(data={'subject': 'My Subject'})
```

```
>>> print (bound_form['subject'].data)
My Subject
```

**BoundField.errors**

A *list-like object* that is displayed as an HTML `<ul class="errorlist">` when printed:

```
>>> data = {'subject': 'hi', 'message': '', 'sender': '', 'cc_myself': ''}
>>> f = ContactForm(data, auto_id=False)
>>> print (f['message'])
<input type="text" name="message" required />
>>> f['message'].errors
['This field is required.']
>>> print (f['message'].errors)
<ul class="errorlist"><li>This field is required.</li></ul>
>>> f['subject'].errors
[]
>>> print (f['subject'].errors)

>>> str(f['subject'].errors)
''
```

**BoundField.field**

The form *Field* instance from the form class that this *BoundField* wraps.

**BoundField.form**

The *Form* instance this *BoundField* is bound to.

**BoundField.help\_text**

The *help\_text* of the field.

**BoundField.html\_name**

The name that will be used in the widget's HTML name attribute. It takes the form *prefix* into account.

**BoundField.id\_for\_label**

Use this property to render the ID of this field. For example, if you are manually constructing a `<label>` in your template (despite the fact that `label_tag()` will do this for you):

```
<label for="{{ form.my_field.id_for_label }}">...</label>{{ my_field }}
```

By default, this will be the field's name prefixed by `id_` ("id\_my\_field" for the example above). You may modify the ID by setting *attrs* on the field's widget. For example, declaring a field like this:

```
my_field = forms.CharField(widget=forms.TextInput(attrs={'id': 'myFIELD'}))
```

and using the template above, would render something like:

```
<label for="myFIELD">...</label><input id="myFIELD" type="text" name="my_field"
↪required />
```

**BoundField.is\_hidden**

Returns True if this *BoundField*'s widget is hidden.

**BoundField.label**

The *label* of the field. This is used in `label_tag()`.

**BoundField.name**

The name of this field in the form:

```
>>> f = ContactForm()
>>> print (f['subject'].name)
subject
>>> print (f['message'].name)
message
```

## Methods of BoundField

**BoundField.as\_hidden** (*attrs=None, \*\*kwargs*)

Returns a string of HTML for representing this as an `<input type="hidden">`.

*\*\*kwargs* are passed to `as_widget()`.

This method is primarily used internally. You should use a widget instead.

**BoundField.as\_widget** (*widget=None, attrs=None, only\_initial=False*)

Renders the field by rendering the passed widget, adding any HTML attributes passed as *attrs*. If no widget is specified, then the field's default widget will be used.

*only\_initial* is used by Django internals and should not be set explicitly.

**BoundField.css\_classes** ()

When you use Django's rendering shortcuts, CSS classes are used to indicate required form fields or fields that contain errors. If you're manually rendering a form, you can access these CSS classes using the `css_classes` method:

```
>>> f = ContactForm(data={'message': ''})
>>> f['message'].css_classes()
'required'
```

If you want to provide some additional classes in addition to the error and required classes that may be required, you can provide those classes as an argument:

```
>>> f = ContactForm(data={'message': ''})
>>> f['message'].css_classes('foo bar')
'foo bar required'
```

**BoundField.label\_tag** (*contents=None, attrs=None, label\_suffix=None*)

To separately render the label tag of a form field, you can call its `label_tag()` method:

```
>>> f = ContactForm(data={'message': ''})
>>> print (f['message'].label_tag())
<label for="id_message">Message:</label>
```

You can provide the `contents` parameter which will replace the auto-generated label tag. An `attrs` dictionary may contain additional attributes for the `<label>` tag.

The HTML that's generated includes the form's `label_suffix` (a colon, by default) or, if set, the current field's `label_suffix`. The optional `label_suffix` parameter allows you to override any previously set suffix. For example, you can use an empty string to hide the label on selected fields. If you need to do this in a template, you could write a custom filter to allow passing parameters to `label_tag`.

**BoundField.value** ()

Use this method to render the raw value of this field as it would be rendered by a `Widget`:

```
>>> initial = {'subject': 'welcome'}
>>> unbound_form = ContactForm(initial=initial)
```

```
>>> bound_form = ContactForm(data={'subject': 'hi'}, initial=initial)
>>> print (unbound_form['subject'].value())
welcome
>>> print (bound_form['subject'].value())
hi
```

## Customizing BoundField

If you need to access some additional information about a form field in a template and using a subclass of `Field` isn't sufficient, consider also customizing `BoundField`.

A custom form field can override `get_bound_field()`:

`Field.get_bound_field(form, field_name)`

Takes an instance of `Form` and the name of the field. The return value will be used when accessing the field in a template. Most likely it will be an instance of a subclass of `BoundField`.

If you have a `GPSCoordinatesField`, for example, and want to be able to access additional information about the coordinates in a template, this could be implemented as follows:

```
class GPSCoordinatesBoundField(BoundField):
    @property
    def country(self):
        """
        Return the country the coordinates lie in or None if it can't be
        determined.
        """
        value = self.value()
        if value:
            return get_country_from_coordinates(value)
        else:
            return None

class GPSCoordinatesField(Field):
    def get_bound_field(self, form, field_name):
        return GPSCoordinatesBoundField(form, self, field_name)
```

Now you can access the country in a template with `{{ form.coordinates.country }}`.

## Binding uploaded files to a form

Dealing with forms that have `FileField` and `ImageField` fields is a little more complicated than a normal form.

Firstly, in order to upload files, you'll need to make sure that your `<form>` element correctly defines the `enctype` as `"multipart/form-data"`:

```
<form enctype="multipart/form-data" method="post" action="/foo/">
```

Secondly, when you use the form, you need to bind the file data. File data is handled separately to normal form data, so when your form contains a `FileField` and `ImageField`, you will need to specify a second argument when you bind your form. So if we extend our `ContactForm` to include an `ImageField` called `mugshot`, we need to bind the file data containing the mugshot image:

```
# Bound form with an image field
>>> from django.core.files.uploadedfile import SimpleUploadedFile
>>> data = {'subject': 'hello',
```

```
...         'message': 'Hi there',
...         'sender': 'foo@example.com',
...         'cc_myself': True}
>>> file_data = {'mugshot': SimpleUploadedFile('face.jpg', <file data>)}
>>> f = ContactFormWithMugshot(data, file_data)
```

In practice, you will usually specify `request.FILES` as the source of file data (just like you use `request.POST` as the source of form data):

```
# Bound form with an image field, data from the request
>>> f = ContactFormWithMugshot(request.POST, request.FILES)
```

Constructing an unbound form is the same as always – just omit both form data *and* file data:

```
# Unbound form with an image field
>>> f = ContactFormWithMugshot()
```

## Testing for multipart forms

Form.`is_multipart()`

If you're writing reusable views or templates, you may not know ahead of time whether your form is a multipart form or not. The `is_multipart()` method tells you whether the form requires multipart encoding for submission:

```
>>> f = ContactFormWithMugshot()
>>> f.is_multipart()
True
```

Here's an example of how you might use this in a template:

```
{% if form.is_multipart %}
    <form enctype="multipart/form-data" method="post" action="/foo/">
{% else %}
    <form method="post" action="/foo/">
{% endif %}
{{ form }}
</form>
```

## Subclassing forms

If you have multiple `Form` classes that share fields, you can use subclassing to remove redundancy.

When you subclass a custom `Form` class, the resulting subclass will include all fields of the parent class(es), followed by the fields you define in the subclass.

In this example, `ContactFormWithPriority` contains all the fields from `ContactForm`, plus an additional field, `priority`. The `ContactForm` fields are ordered first:

```
>>> class ContactFormWithPriority(ContactForm):
...     priority = forms.CharField()
>>> f = ContactFormWithPriority(auto_id=False)
>>> print(f.as_ul())
<li>Subject: <input type="text" name="subject" maxlength="100" required /></li>
<li>Message: <input type="text" name="message" required /></li>
<li>Sender: <input type="email" name="sender" required /></li>
```

```
<li>Cc myself: <input type="checkbox" name="cc_myself" /></li>
<li>Priority: <input type="text" name="priority" required /></li>
```

It's possible to subclass multiple forms, treating forms as mixins. In this example, `BeatleForm` subclasses both `PersonForm` and `InstrumentForm` (in that order), and its field list includes the fields from the parent classes:

```
>>> from django import forms
>>> class PersonForm(forms.Form):
...     first_name = forms.CharField()
...     last_name = forms.CharField()
>>> class InstrumentForm(forms.Form):
...     instrument = forms.CharField()
>>> class BeatleForm(InstrumentForm, PersonForm):
...     haircut_type = forms.CharField()
>>> b = BeatleForm(auto_id=False)
>>> print(b.as_ul())
<li>First name: <input type="text" name="first_name" required /></li>
<li>Last name: <input type="text" name="last_name" required /></li>
<li>Instrument: <input type="text" name="instrument" required /></li>
<li>Haircut type: <input type="text" name="haircut_type" required /></li>
```

It's possible to declaratively remove a `Field` inherited from a parent class by setting the name of the field to `None` on the subclass. For example:

```
>>> from django import forms
>>> class ParentForm(forms.Form):
...     name = forms.CharField()
...     age = forms.IntegerField()
>>> class ChildForm(ParentForm):
...     name = None
>>> ChildForm().fields.keys()
... ['age']
```

## Prefixes for forms

### Form.`prefix`

You can put several Django forms inside one `<form>` tag. To give each `Form` its own namespace, use the `prefix` keyword argument:

```
>>> mother = PersonForm(prefix="mother")
>>> father = PersonForm(prefix="father")
>>> print(mother.as_ul())
<li><label for="id_mother-first_name">First name:</label> <input type="text" name=
↪ "mother-first_name" id="id_mother-first_name" required /></li>
<li><label for="id_mother-last_name">Last name:</label> <input type="text" name=
↪ "mother-last_name" id="id_mother-last_name" required /></li>
>>> print(father.as_ul())
<li><label for="id_father-first_name">First name:</label> <input type="text" name=
↪ "father-first_name" id="id_father-first_name" required /></li>
<li><label for="id_father-last_name">Last name:</label> <input type="text" name=
↪ "father-last_name" id="id_father-last_name" required /></li>
```

The `prefix` can also be specified on the form class:

```
>>> class PersonForm(forms.Form):
...     ...
...     prefix = 'person'
```

The ability to specify `prefix` on the form class was added.

## 6.12.2 Form fields

**class** `Field` (*\*\*kwargs*)

When you create a `Form` class, the most important part is defining the fields of the form. Each field has custom validation logic, along with a few other hooks.

`Field.clean` (*value*)

Although the primary way you'll use `Field` classes is in `Form` classes, you can also instantiate them and use them directly to get a better idea of how they work. Each `Field` instance has a `clean()` method, which takes a single argument and either raises a `django.forms.ValidationError` exception or returns the clean value:

```
>>> from django import forms
>>> f = forms.EmailField()
>>> f.clean('foo@example.com')
'foo@example.com'
>>> f.clean('invalid email address')
Traceback (most recent call last):
...
ValidationError: ['Enter a valid email address.']
```

### Core field arguments

Each `Field` class constructor takes at least these arguments. Some `Field` classes take additional, field-specific arguments, but the following should *always* be accepted:

#### `required`

`Field.required`

By default, each `Field` class assumes the value is required, so if you pass an empty value – either `None` or the empty string (`""`) – then `clean()` will raise a `ValidationError` exception:

```
>>> from django import forms
>>> f = forms.CharField()
>>> f.clean('foo')
'foo'
>>> f.clean('')
Traceback (most recent call last):
...
ValidationError: ['This field is required.']
>>> f.clean(None)
Traceback (most recent call last):
...
ValidationError: ['This field is required.']
>>> f.clean(' ')
' '
>>> f.clean(0)
```

```
'0'
>>> f.clean(True)
'True'
>>> f.clean(False)
'False'
```

To specify that a field is *not* required, pass `required=False` to the `Field` constructor:

```
>>> f = forms.CharField(required=False)
>>> f.clean('foo')
'foo'
>>> f.clean('')
''
>>> f.clean(None)
''
>>> f.clean(0)
'0'
>>> f.clean(True)
'True'
>>> f.clean(False)
'False'
```

If a `Field` has `required=False` and you pass `clean()` an empty value, then `clean()` will return a *normalized* empty value rather than raising `ValidationError`. For `CharField`, this will be a Unicode empty string. For other `Field` classes, it might be `None`. (This varies from field to field.)

Widgets of required form fields have the `required` HTML attribute. Set the `Form.use_required_attribute` attribute to `False` to disable it. The `required` attribute isn't included on forms of formsets because the browser validation may not be correct when adding and deleting formsets.

Support for the `required` HTML attribute was added.

## label

### Field.label

The `label` argument lets you specify the “human-friendly” label for this field. This is used when the `Field` is displayed in a `Form`.

As explained in “Outputting forms as HTML” above, the default label for a `Field` is generated from the field name by converting all underscores to spaces and upper-casing the first letter. Specify `label` if that default behavior doesn't result in an adequate label.

Here's a full example `Form` that implements `label` for two of its fields. We've specified `auto_id=False` to simplify the output:

```
>>> from django import forms
>>> class CommentForm(forms.Form):
...     name = forms.CharField(label='Your name')
...     url = forms.URLField(label='Your website', required=False)
...     comment = forms.CharField()
>>> f = CommentForm(auto_id=False)
>>> print(f)
<tr><th>Your name:</th><td><input type="text" name="name" required /></td></tr>
<tr><th>Your website:</th><td><input type="url" name="url" /></td></tr>
<tr><th>Comment:</th><td><input type="text" name="comment" required /></td></tr>
```

## label\_suffix

### Field.label\_suffix

The `label_suffix` argument lets you override the form’s `label_suffix` on a per-field basis:

```
>>> class ContactForm(forms.Form):
...     age = forms.IntegerField()
...     nationality = forms.CharField()
...     captcha_answer = forms.IntegerField(label='2 + 2', label_suffix=' =')
>>> f = ContactForm(label_suffix='?')
>>> print(f.as_p())
<p><label for="id_age">Age?</label> <input id="id_age" name="age" type="number"
↳required /></p>
<p><label for="id_nationality">Nationality?</label> <input id="id_nationality" name=
↳"nationality" type="text" required /></p>
<p><label for="id_captcha_answer">2 + 2 =</label> <input id="id_captcha_answer" name=
↳"captcha_answer" type="number" required /></p>
```

## initial

### Field.initial

The `initial` argument lets you specify the initial value to use when rendering this `Field` in an unbound `Form`.

To specify dynamic initial data, see the `Form.initial` parameter.

The use-case for this is when you want to display an “empty” form in which a field is initialized to a particular value. For example:

```
>>> from django import forms
>>> class CommentForm(forms.Form):
...     name = forms.CharField(initial='Your name')
...     url = forms.URLField(initial='http://')
...     comment = forms.CharField()
>>> f = CommentForm(auto_id=False)
>>> print(f)
<tr><th>Name:</th><td><input type="text" name="name" value="Your name" required /></td></tr>
↳<tr>
<tr><th>Url:</th><td><input type="url" name="url" value="http://" required /></td></tr>
↳<tr>
<tr><th>Comment:</th><td><input type="text" name="comment" required /></td></tr>
```

You may be thinking, why not just pass a dictionary of the initial values as data when displaying the form? Well, if you do that, you’ll trigger validation, and the HTML output will include any validation errors:

```
>>> class CommentForm(forms.Form):
...     name = forms.CharField()
...     url = forms.URLField()
...     comment = forms.CharField()
>>> default_data = {'name': 'Your name', 'url': 'http://'}
>>> f = CommentForm(default_data, auto_id=False)
>>> print(f)
<tr><th>Name:</th><td><input type="text" name="name" value="Your name" required /></td></tr>
↳<tr>
<tr><th>Url:</th><td><ul class="errorlist"><li>Enter a valid URL.</li></ul><input
↳type="url" name="url" value="http://" required /></td></tr>
<tr><th>Comment:</th><td><ul class="errorlist"><li>This field is required.</li></ul>
↳<input type="text" name="comment" required /></td></tr>
```

This is why `initial` values are only displayed for unbound forms. For bound forms, the HTML output will use the bound data.

Also note that `initial` values are *not* used as “fallback” data in validation if a particular field’s value is not given. `initial` values are *only* intended for initial form display:

```
>>> class CommentForm(forms.Form):
...     name = forms.CharField(initial='Your name')
...     url = forms.URLField(initial='http://')
...     comment = forms.CharField()
>>> data = {'name': '', 'url': '', 'comment': 'Foo'}
>>> f = CommentForm(data)
>>> f.is_valid()
False
# The form does *not* fall back to using the initial values.
>>> f.errors
{'url': ['This field is required.'], 'name': ['This field is required.']}
```

Instead of a constant, you can also pass any callable:

```
>>> import datetime
>>> class DateForm(forms.Form):
...     day = forms.DateField(initial=datetime.date.today)
>>> print(DateForm())
<tr><th>Day:</th><td><input type="text" name="day" value="12/23/2008" required /><td>
↪</tr>
```

The callable will be evaluated only when the unbound form is displayed, not when it is defined.

## widget

### Field.widget

The `widget` argument lets you specify a `Widget` class to use when rendering this `Field`. See [Widgets](#) for more information.

## help\_text

### Field.help\_text

The `help_text` argument lets you specify descriptive text for this `Field`. If you provide `help_text`, it will be displayed next to the `Field` when the `Field` is rendered by one of the convenience `Form` methods (e.g., `as_ul()`).

Like the model field’s `help_text`, this value isn’t HTML-escaped in automatically-generated forms.

Here’s a full example `Form` that implements `help_text` for two of its fields. We’ve specified `auto_id=False` to simplify the output:

```
>>> from django import forms
>>> class HelpTextContactForm(forms.Form):
...     subject = forms.CharField(max_length=100, help_text='100 characters max.')
...     message = forms.CharField()
...     sender = forms.EmailField(help_text='A valid email address, please.')
...     cc_myself = forms.BooleanField(required=False)
>>> f = HelpTextContactForm(auto_id=False)
```

```
>>> print(f.as_table())
<tr><th>Subject:</th><td><input type="text" name="subject" maxlength="100" required />
↳<br /><span class="helptext">100 characters max.</span></td></tr>
<tr><th>Message:</th><td><input type="text" name="message" required /></td></tr>
<tr><th>Sender:</th><td><input type="email" name="sender" required /><br />A valid_
↳email address, please.</td></tr>
<tr><th>Cc myself:</th><td><input type="checkbox" name="cc_myself" /></td></tr>
>>> print(f.as_ul())
<li>Subject: <input type="text" name="subject" maxlength="100" required /> <span_
↳class="helptext">100 characters max.</span></li>
<li>Message: <input type="text" name="message" required /></li>
<li>Sender: <input type="email" name="sender" required /> A valid email address,_
↳please.</li>
<li>Cc myself: <input type="checkbox" name="cc_myself" /></li>
>>> print(f.as_p())
<p>Subject: <input type="text" name="subject" maxlength="100" required /> <span class=
↳"helptext">100 characters max.</span></p>
<p>Message: <input type="text" name="message" required /></p>
<p>Sender: <input type="email" name="sender" required /> A valid email address,_
↳please.</p>
<p>Cc myself: <input type="checkbox" name="cc_myself" /></p>
```

## error\_messages

### Field.error\_messages

The `error_messages` argument lets you override the default messages that the field will raise. Pass in a dictionary with keys matching the error messages you want to override. For example, here is the default error message:

```
>>> from django import forms
>>> generic = forms.CharField()
>>> generic.clean('')
Traceback (most recent call last):
...
ValidationError: ['This field is required.']
```

And here is a custom error message:

```
>>> name = forms.CharField(error_messages={'required': 'Please enter your name'})
>>> name.clean('')
Traceback (most recent call last):
...
ValidationError: ['Please enter your name']
```

In the *built-in Field classes* section below, each `Field` defines the error message keys it uses.

## validators

### Field.validators

The `validators` argument lets you provide a list of validation functions for this field.

See the *validators documentation* for more information.

## localize

### Field.localize

The `localize` argument enables the localization of form data input, as well as the rendered output.

See the *format localization* documentation for more information.

## disabled

### Field.disabled

The `disabled` boolean argument, when set to `True`, disables a form field using the `disabled` HTML attribute so that it won't be editable by users. Even if a user tampers with the field's value submitted to the server, it will be ignored in favor of the value from the form's initial data.

## Checking if the field data has changed

### has\_changed()

#### Field.has\_changed()

The `has_changed()` method is used to determine if the field value has changed from the initial value. Returns `True` or `False`.

See the *Form.has\_changed()* documentation for more information.

## Built-in Field classes

Naturally, the `forms` library comes with a set of `Field` classes that represent common validation needs. This section documents each built-in field.

For each field, we describe the default widget used if you don't specify `widget`. We also specify the value returned when you provide an empty value (see the section on `required` above to understand what that means).

### BooleanField

```
class BooleanField(**kwargs)
```

- Default widget: `CheckboxInput`
- Empty value: `False`
- Normalizes to: A Python `True` or `False` value.
- Validates that the value is `True` (e.g. the check box is checked) if the field has `required=True`.
- Error message keys: `required`

---

**Note:** Since all `Field` subclasses have `required=True` by default, the validation condition here is important. If you want to include a boolean in your form that can be either `True` or `False` (e.g. a checked or unchecked checkbox), you must remember to pass in `required=False` when creating the `BooleanField`.

---

## CharField

**class CharField** (\*\*kwargs)

- Default widget: *TextInput*
- Empty value: '' (an empty string)
- Normalizes to: A Unicode object.
- Validates `max_length` or `min_length`, if they are provided. Otherwise, all inputs are valid.
- Error message keys: `required`, `max_length`, `min_length`

Has three optional arguments for validation:

**max\_length**

**min\_length**

If provided, these arguments ensure that the string is at most or at least the given length.

**strip**

If `True` (default), the value will be stripped of leading and trailing whitespace.

## ChoiceField

**class ChoiceField** (\*\*kwargs)

- Default widget: *Select*
- Empty value: '' (an empty string)
- Normalizes to: A Unicode object.
- Validates that the given value exists in the list of choices.
- Error message keys: `required`, `invalid_choice`

The `invalid_choice` error message may contain `%(value)s`, which will be replaced with the selected choice.

Takes one extra required argument:

**choices**

Either an iterable (e.g., a list or tuple) of 2-tuples to use as choices for this field, or a callable that returns such an iterable. This argument accepts the same formats as the `choices` argument to a model field. See the *model field reference documentation on choices* for more details. If the argument is a callable, it is evaluated each time the field's form is initialized.

## TypedChoiceField

**class TypedChoiceField** (\*\*kwargs)

Just like a *ChoiceField*, except *TypedChoiceField* takes two extra arguments, *coerce* and *empty\_value*.

- Default widget: *Select*
- Empty value: Whatever you've given as *empty\_value*.
- Normalizes to: A value of the type provided by the *coerce* argument.
- Validates that the given value exists in the list of choices and can be coerced.

- Error message keys: `required`, `invalid_choice`

Takes extra arguments:

#### **coerce**

A function that takes one argument and returns a coerced value. Examples include the built-in `int`, `float`, `bool` and other types. Defaults to an identity function. Note that coercion happens after input validation, so it is possible to coerce to a value not present in `choices`.

#### **empty\_value**

The value to use to represent “empty.” Defaults to the empty string; `None` is another common choice here. Note that this value will not be coerced by the function given in the `coerce` argument, so choose it accordingly.

## DateField

**class** `DateField` (\*\*kwargs)

- Default widget: `DateInput`
- Empty value: `None`
- Normalizes to: A Python `datetime.date` object.
- Validates that the given value is either a `datetime.date`, `datetime.datetime` or string formatted in a particular date format.
- Error message keys: `required`, `invalid`

Takes one optional argument:

#### **input\_formats**

A list of formats used to attempt to convert a string to a valid `datetime.date` object.

If no `input_formats` argument is provided, the default input formats are:

```
[ '%Y-%m-%d',      # '2006-10-25'
  '%m/%d/%Y',      # '10/25/2006'
  '%m/%d/%y' ]     # '10/25/06'
```

Additionally, if you specify `USE_L10N=False` in your settings, the following will also be included in the default input formats:

```
[ '%b %d %Y',      # 'Oct 25 2006'
  '%b %d, %Y',      # 'Oct 25, 2006'
  '%d %b %Y',      # '25 Oct 2006'
  '%d %b, %Y',      # '25 Oct, 2006'
  '%B %d %Y',      # 'October 25 2006'
  '%B %d, %Y',      # 'October 25, 2006'
  '%d %B %Y',      # '25 October 2006'
  '%d %B, %Y' ]     # '25 October, 2006'
```

See also [format localization](#).

## DateTimeField

**class** `DateTimeField` (\*\*kwargs)

- Default widget: `DateTimeInput`

- Empty value: None
- Normalizes to: A Python `datetime.datetime` object.
- Validates that the given value is either a `datetime.datetime`, `datetime.date` or string formatted in a particular datetime format.
- Error message keys: `required`, `invalid`

Takes one optional argument:

**input\_formats**

A list of formats used to attempt to convert a string to a valid `datetime.datetime` object.

If no `input_formats` argument is provided, the default input formats are:

```
[ '%Y-%m-%d %H:%M:%S',      # '2006-10-25 14:30:59'
  '%Y-%m-%d %H:%M',        # '2006-10-25 14:30'
  '%Y-%m-%d',              # '2006-10-25'
  '%m/%d/%Y %H:%M:%S',    # '10/25/2006 14:30:59'
  '%m/%d/%Y %H:%M',       # '10/25/2006 14:30'
  '%m/%d/%Y',             # '10/25/2006'
  '%m/%d/%Y %H:%M:%S',    # '10/25/06 14:30:59'
  '%m/%d/%Y %H:%M',       # '10/25/06 14:30'
  '%m/%d/%Y' ]           # '10/25/06'
```

See also [format localization](#).

## DecimalField

**class** `DecimalField` (*\*\*kwargs*)

- Default widget: `NumberInput` when `Field.localize` is `False`, else `TextInput`.
- Empty value: None
- Normalizes to: A Python decimal.
- Validates that the given value is a decimal. Leading and trailing whitespace is ignored.
- Error message keys: `required`, `invalid`, `max_value`, `min_value`, `max_digits`, `max_decimal_places`, `max_whole_digits`

The `max_value` and `min_value` error messages may contain `%(limit_value)s`, which will be substituted by the appropriate limit. Similarly, the `max_digits`, `max_decimal_places` and `max_whole_digits` error messages may contain `%(max)s`.

Takes four optional arguments:

**max\_value****min\_value**

These control the range of values permitted in the field, and should be given as `decimal.Decimal` values.

**max\_digits**

The maximum number of digits (those before the decimal point plus those after the decimal point, with leading zeros stripped) permitted in the value.

**decimal\_places**

The maximum number of decimal places permitted.

## DurationField

**class DurationField** (\*\*kwargs)

- Default widget: *TextInput*
- Empty value: None
- Normalizes to: A Python `timedelta`.
- Validates that the given value is a string which can be converted into a `timedelta`.
- Error message keys: `required`, `invalid`.

Accepts any format understood by `parse_duration()`.

## EmailField

**class EmailField** (\*\*kwargs)

- Default widget: *EmailInput*
- Empty value: '' (an empty string)
- Normalizes to: A Unicode object.
- Validates that the given value is a valid email address, using a moderately complex regular expression.
- Error message keys: `required`, `invalid`

Has two optional arguments for validation, `max_length` and `min_length`. If provided, these arguments ensure that the string is at most or at least the given length.

## FileField

**class FileField** (\*\*kwargs)

- Default widget: *ClearableFileInput*
- Empty value: None
- Normalizes to: An `UploadedFile` object that wraps the file content and file name into a single object.
- Can validate that non-empty file data has been bound to the form.
- Error message keys: `required`, `invalid`, `missing`, `empty`, `max_length`

Has two optional arguments for validation, `max_length` and `allow_empty_file`. If provided, these ensure that the file name is at most the given length, and that validation will succeed even if the file content is empty.

To learn more about the `UploadedFile` object, see the [file uploads documentation](#).

When you use a `FileField` in a form, you must also remember to *bind the file data to the form*.

The `max_length` error refers to the length of the filename. In the error message for that key, `%(max)d` will be replaced with the maximum filename length and `%(length)d` will be replaced with the current filename length.

## FilePathField

**class** `FilePathField` (*\*\*kwargs*)

- Default widget: `Select`
- Empty value: `None`
- Normalizes to: A unicode object
- Validates that the selected choice exists in the list of choices.
- Error message keys: `required`, `invalid_choice`

The field allows choosing from files inside a certain directory. It takes five extra arguments; only `path` is required:

### **path**

The absolute path to the directory whose contents you want listed. This directory must exist.

### **recursive**

If `False` (the default) only the direct contents of `path` will be offered as choices. If `True`, the directory will be descended into recursively and all descendants will be listed as choices.

### **match**

A regular expression pattern; only files with names matching this expression will be allowed as choices.

### **allow\_files**

Optional. Either `True` or `False`. Default is `True`. Specifies whether files in the specified location should be included. Either this or `allow_folders` must be `True`.

### **allow\_folders**

Optional. Either `True` or `False`. Default is `False`. Specifies whether folders in the specified location should be included. Either this or `allow_files` must be `True`.

## FloatField

**class** `FloatField` (*\*\*kwargs*)

- Default widget: `NumberInput` when `Field.localize` is `False`, else `TextInput`.
- Empty value: `None`
- Normalizes to: A Python float.
- Validates that the given value is a float. Leading and trailing whitespace is allowed, as in Python's `float()` function.
- Error message keys: `required`, `invalid`, `max_value`, `min_value`

Takes two optional arguments for validation, `max_value` and `min_value`. These control the range of values permitted in the field.

## ImageField

**class** `ImageField` (*\*\*kwargs*)

- Default widget: `ClearableFileInput`
- Empty value: `None`
- Normalizes to: An `UploadedFile` object that wraps the file content and file name into a single object.

- Validates that file data has been bound to the form, and that the file is of an image format understood by Pillow.
- Error message keys: `required`, `invalid`, `missing`, `empty`, `invalid_image`

Using an `ImageField` requires that `Pillow` is installed with support for the image formats you use. If you encounter a `corrupt image` error when you upload an image, it usually means that Pillow doesn't understand its format. To fix this, install the appropriate library and reinstall Pillow.

When you use an `ImageField` on a form, you must also remember to *bind the file data to the form*.

After the field has been cleaned and validated, the `UploadedFile` object will have an additional `image` attribute containing the Pillow `Image` instance used to check if the file was a valid image. Also, `UploadedFile.content_type` will be updated with the image's content type if Pillow can determine it, otherwise it will be set to `None`.

## IntegerField

**class IntegerField** (\*\*kwargs)

- Default widget: `NumberInput` when `Field.localize` is `False`, else `TextInput`.
- Empty value: `None`
- Normalizes to: A Python integer or long integer.
- Validates that the given value is an integer. Leading and trailing whitespace is allowed, as in Python's `int()` function.
- Error message keys: `required`, `invalid`, `max_value`, `min_value`

The `max_value` and `min_value` error messages may contain `%(limit_value)s`, which will be substituted by the appropriate limit.

Takes two optional arguments for validation:

**max\_value**

**min\_value**

These control the range of values permitted in the field.

## GenericIPAddressField

**class GenericIPAddressField** (\*\*kwargs)

A field containing either an IPv4 or an IPv6 address.

- Default widget: `TextInput`
- Empty value: `' '` (an empty string)
- Normalizes to: A Unicode object. IPv6 addresses are normalized as described below.
- Validates that the given value is a valid IP address.
- Error message keys: `required`, `invalid`

The IPv6 address normalization follows [RFC 4291#section-2.2](#) section 2.2, including using the IPv4 format suggested in paragraph 3 of that section, like `::ffff:192.0.2.0`. For example, `2001:0::0:01` would be normalized to `2001::1`, and `::ffff:0a0a:0a0a` to `::ffff:10.10.10.10`. All characters are converted to lowercase.

Takes two optional arguments:

**protocol**

Limits valid inputs to the specified protocol. Accepted values are `both` (default), `IPv4` or `IPv6`. Matching is case insensitive.

**unpack\_ipv4**

Unpacks IPv4 mapped addresses like `::ffff:192.0.2.1`. If this option is enabled that address would be unpacked to `192.0.2.1`. Default is disabled. Can only be used when `protocol` is set to `'both'`.

## MultipleChoiceField

**class MultipleChoiceField** (\*\*kwargs)

- Default widget: *SelectMultiple*
- Empty value: [] (an empty list)
- Normalizes to: A list of Unicode objects.
- Validates that every value in the given list of values exists in the list of choices.
- Error message keys: `required`, `invalid_choice`, `invalid_list`

The `invalid_choice` error message may contain `%(value)s`, which will be replaced with the selected choice.

Takes one extra required argument, `choices`, as for *ChoiceField*.

## TypedMultipleChoiceField

**class TypedMultipleChoiceField** (\*\*kwargs)

Just like a *MultipleChoiceField*, except *TypedMultipleChoiceField* takes two extra arguments, `coerce` and `empty_value`.

- Default widget: *SelectMultiple*
- Empty value: Whatever you've given as `empty_value`
- Normalizes to: A list of values of the type provided by the `coerce` argument.
- Validates that the given values exists in the list of choices and can be coerced.
- Error message keys: `required`, `invalid_choice`

The `invalid_choice` error message may contain `%(value)s`, which will be replaced with the selected choice.

Takes two extra arguments, `coerce` and `empty_value`, as for *TypedChoiceField*.

## NullBooleanField

**class NullBooleanField** (\*\*kwargs)

- Default widget: *NullBooleanSelect*
- Empty value: `None`
- Normalizes to: A Python `True`, `False` or `None` value.
- Validates nothing (i.e., it never raises a `ValidationError`).

## RegexField

**class** `RegexField` (\*\*kwargs)

- Default widget: *TextInput*
- Empty value: '' (an empty string)
- Normalizes to: A Unicode object.
- Validates that the given value matches against a certain regular expression.
- Error message keys: `required`, `invalid`

Takes one required argument:

### **regex**

A regular expression specified either as a string or a compiled regular expression object.

Also takes `max_length`, `min_length`, and `strip`, which work just as they do for *CharField*.

### **strip**

Defaults to `False`. If enabled, stripping will be applied before the regex validation.

## SlugField

**class** `SlugField` (\*\*kwargs)

- Default widget: *TextInput*
- Empty value: '' (an empty string)
- Normalizes to: A Unicode object.
- Validates that the given value contains only letters, numbers, underscores, and hyphens.
- Error messages: `required`, `invalid`

This field is intended for use in representing a model *SlugField* in forms.

Takes an optional parameter:

### **allow\_unicode**

A boolean instructing the field to accept Unicode letters in addition to ASCII letters. Defaults to `False`.

## TimeField

**class** `TimeField` (\*\*kwargs)

- Default widget: *TextInput*
- Empty value: `None`
- Normalizes to: A Python `datetime.time` object.
- Validates that the given value is either a `datetime.time` or string formatted in a particular time format.
- Error message keys: `required`, `invalid`

Takes one optional argument:

### **input\_formats**

A list of formats used to attempt to convert a string to a valid `datetime.time` object.

If no `input_formats` argument is provided, the default input formats are:

```
'%H:%M:%S',      # '14:30:59'
'%H:%M',         # '14:30'
```

## URLField

**class** `URLField` (*\*\*kwargs*)

- Default widget: `URLInput`
- Empty value: `' '` (an empty string)
- Normalizes to: A Unicode object.
- Validates that the given value is a valid URL.
- Error message keys: `required`, `invalid`

Takes the following optional arguments:

**max\_length**

**min\_length**

These are the same as `CharField.max_length` and `CharField.min_length`.

## UUIDField

**class** `UUIDField` (*\*\*kwargs*)

- Default widget: `TextInput`
- Empty value: `' '` (an empty string)
- Normalizes to: A `UUID` object.
- Error message keys: `required`, `invalid`

This field will accept any string format accepted as the `hex` argument to the `UUID` constructor.

## Slightly complex built-in Field classes

### ComboField

**class** `ComboField` (*\*\*kwargs*)

- Default widget: `TextInput`
- Empty value: `' '` (an empty string)
- Normalizes to: A Unicode object.
- Validates the given value against each of the fields specified as an argument to the `ComboField`.
- Error message keys: `required`, `invalid`

Takes one extra required argument:

**fields**

The list of fields that should be used to validate the field's value (in the order in which they are provided).

```
>>> from django.forms import ComboField
>>> f = ComboField(fields=[CharField(max_length=20), EmailField()])
>>> f.clean('test@example.com')
'test@example.com'
>>> f.clean('longemailaddress@example.com')
Traceback (most recent call last):
...
ValidationError: ['Ensure this value has at most 20 characters (it has 28).']
```

## MultiValueField

**class MultiValueField** (*fields=()*, *\*\*kwargs*)

- Default widget: *TextInput*
- Empty value: '' (an empty string)
- Normalizes to: the type returned by the *compress* method of the subclass.
- Validates the given value against each of the fields specified as an argument to the *MultiValueField*.
- Error message keys: *required*, *invalid*, *incomplete*

Aggregates the logic of multiple fields that together produce a single value.

This field is abstract and must be subclassed. In contrast with the single-value fields, subclasses of *MultiValueField* must not implement *clean()* but instead - implement *compress()*.

Takes one extra required argument:

### fields

A tuple of fields whose values are cleaned and subsequently combined into a single value. Each value of the field is cleaned by the corresponding field in *fields* – the first value is cleaned by the first field, the second value is cleaned by the second field, etc. Once all fields are cleaned, the list of clean values is combined into a single value by *compress()*.

Also takes one extra optional argument:

### require\_all\_fields

Defaults to *True*, in which case a *required* validation error will be raised if no value is supplied for any field.

When set to *False*, the *Field.required* attribute can be set to *False* for individual fields to make them optional. If no value is supplied for a required field, an *incomplete* validation error will be raised.

A default *incomplete* error message can be defined on the *MultiValueField* subclass, or different messages can be defined on each individual field. For example:

```
from django.core.validators import RegexValidator

class PhoneField(MultiValueField):
    def __init__(self, *args, **kwargs):
        # Define one message for all fields.
        error_messages = {
            'incomplete': 'Enter a country calling code and a phone number.',
        }
        # Or define a different message for each field.
        fields = (
            CharField(
                error_messages={'incomplete': 'Enter a country calling code.'}
            ),
            RegexValidator(
                r'^[0-9]{10}$',
                error_messages={'incomplete': 'Enter a 10 digit phone number.'}
            ),
        )
        super().__init__(fields, *args, **kwargs)
```

```
        validators=[
            RegexValidator(r'^[0-9]+$ ', 'Enter a valid country_
↪calling code.'),
        ],
    ),
    CharField(
        error_messages={'incomplete': 'Enter a phone number.'},
        validators=[RegexValidator(r'^[0-9]+$ ', 'Enter a valid phone_
↪number.')],
    ),
    CharField(
        validators=[RegexValidator(r'^[0-9]+$ ', 'Enter a valid_
↪extension.')],
        required=False,
    ),
)
super(PhoneField, self).__init__(
    error_messages=error_messages, fields=fields,
    require_all_fields=False, *args, **kwargs
)
```

**widget**

Must be a subclass of `django.forms.MultiWidget`. Default value is `TextInput`, which probably is not very useful in this case.

**compress** (*data\_list*)

Takes a list of valid values and returns a “compressed” version of those values – in a single value. For example, `SplitDateTimeField` is a subclass which combines a time field and a date field into a datetime object.

This method must be implemented in the subclasses.

**SplitDateTimeField**

**class SplitDateTimeField** (*\*\*kwargs*)

- Default widget: `SplitDateTimeWidget`
- Empty value: None
- Normalizes to: A Python `datetime.datetime` object.
- Validates that the given value is a `datetime.datetime` or string formatted in a particular datetime format.
- Error message keys: `required`, `invalid`, `invalid_date`, `invalid_time`

Takes two optional arguments:

**input\_date\_formats**

A list of formats used to attempt to convert a string to a valid `datetime.date` object.

If no `input_date_formats` argument is provided, the default input formats for `DateField` are used.

**input\_time\_formats**

A list of formats used to attempt to convert a string to a valid `datetime.time` object.

If no `input_time_formats` argument is provided, the default input formats for `TimeField` are used.

## Fields which handle relationships

Two fields are available for representing relationships between models: `ModelChoiceField` and `ModelMultipleChoiceField`. Both of these fields require a single `queryset` parameter that is used to create the choices for the field. Upon form validation, these fields will place either one model object (in the case of `ModelChoiceField`) or multiple model objects (in the case of `ModelMultipleChoiceField`) into the `cleaned_data` dictionary of the form.

For more complex uses, you can specify `queryset=None` when declaring the form field and then populate the `queryset` in the form's `__init__()` method:

```
class FooMultipleChoiceForm(forms.Form):
    foo_select = forms.ModelMultipleChoiceField(queryset=None)

    def __init__(self, *args, **kwargs):
        super(FooMultipleChoiceForm, self).__init__(*args, **kwargs)
        self.fields['foo_select'].queryset = ...
```

## ModelChoiceField

**class ModelChoiceField** (\*\*kwargs)

- Default widget: `Select`
- Empty value: `None`
- Normalizes to: A model instance.
- Validates that the given id exists in the queryset.
- Error message keys: `required`, `invalid_choice`

Allows the selection of a single model object, suitable for representing a foreign key. Note that the default widget for `ModelChoiceField` becomes impractical when the number of entries increases. You should avoid using it for more than 100 items.

A single argument is required:

### queryset

A `QuerySet` of model objects from which the choices for the field will be derived, and which will be used to validate the user's selection.

`ModelChoiceField` also takes two optional arguments:

### empty\_label

By default the `<select>` widget used by `ModelChoiceField` will have an empty choice at the top of the list. You can change the text of this label (which is "-----" by default) with the `empty_label` attribute, or you can disable the empty label entirely by setting `empty_label` to `None`:

```
# A custom empty label
field1 = forms.ModelChoiceField(queryset=..., empty_label="(Nothing)")

# No empty label
field2 = forms.ModelChoiceField(queryset=..., empty_label=None)
```

Note that if a `ModelChoiceField` is required and has a default initial value, no empty choice is created (regardless of the value of `empty_label`).

**to\_field\_name**

This optional argument is used to specify the field to use as the value of the choices in the field's widget. Be sure it's a unique field for the model, otherwise the selected value could match more than one object. By default it is set to `None`, in which case the primary key of each object will be used. For example:

```
# No custom to_field_name
field1 = forms.ModelChoiceField(queryset=...)
```

would yield:

```
<select id="id_field1" name="field1">
<option value="obj1.pk">Object1</option>
<option value="obj2.pk">Object2</option>
...
</select>
```

and:

```
# to_field_name provided
field2 = forms.ModelChoiceField(queryset=..., to_field_name="name")
```

would yield:

```
<select id="id_field2" name="field2">
<option value="obj1.name">Object1</option>
<option value="obj2.name">Object2</option>
...
</select>
```

The `__str__` (`__unicode__` on Python 2) method of the model will be called to generate string representations of the objects for use in the field's choices; to provide customized representations, subclass `ModelChoiceField` and override `label_from_instance`. This method will receive a model object, and should return a string suitable for representing it. For example:

```
from django.forms import ModelChoiceField

class MyModelChoiceField(ModelChoiceField):
    def label_from_instance(self, obj):
        return "My Object #%i" % obj.id
```

**ModelMultipleChoiceField**

```
class ModelMultipleChoiceField(**kwargs)
```

- Default widget: `SelectMultiple`
- Empty value: An empty `QuerySet` (`self.queryset.none()`)
- Normalizes to: A `QuerySet` of model instances.
- Validates that every id in the given list of values exists in the `queryset`.
- Error message keys: `required`, `list`, `invalid_choice`, `invalid_pk_value`

The `invalid_choice` message may contain `%(value)s` and the `invalid_pk_value` message may contain `%(pk)s`, which will be substituted by the appropriate values.

Allows the selection of one or more model objects, suitable for representing a many-to-many relation. As with `ModelChoiceField`, you can use `label_from_instance` to customize the object representations.

A single argument is required:

**queryset**

Same as `ModelChoiceField.queryset`.

Takes one optional argument:

**to\_field\_name**

Same as `ModelChoiceField.to_field_name`.

## Creating custom fields

If the built-in `Field` classes don't meet your needs, you can easily create custom `Field` classes. To do this, just create a subclass of `django.forms.Field`. Its only requirements are that it implement a `clean()` method and that its `__init__()` method accept the core arguments mentioned above (`required`, `label`, `initial`, `widget`, `help_text`).

You can also customize how a field will be accessed by overriding `get_bound_field()`.

### 6.12.3 Model Form Functions

Model Form API reference. For introductory material about model forms, see the *Creating forms from models* topic guide.

#### `modelform_factory`

**modelform\_factory** (*model*, *form=ModelForm*, *fields=None*, *exclude=None*, *formfield\_callback=None*, *wid-gets=None*, *localized\_fields=None*, *labels=None*, *help\_texts=None*, *error\_messages=None*, *field\_classes=None*)

Returns a `ModelForm` class for the given `model`. You can optionally pass a `form` argument to use as a starting point for constructing the `ModelForm`.

`fields` is an optional list of field names. If provided, only the named fields will be included in the returned fields.

`exclude` is an optional list of field names. If provided, the named fields will be excluded from the returned fields, even if they are listed in the `fields` argument.

`formfield_callback` is a callable that takes a model field and returns a form field.

`wid-gets` is a dictionary of model field names mapped to a widget.

`localized_fields` is a list of names of fields which should be localized.

`labels` is a dictionary of model field names mapped to a label.

`help_texts` is a dictionary of model field names mapped to a help text.

`error_messages` is a dictionary of model field names mapped to a dictionary of error messages.

`field_classes` is a dictionary of model field names mapped to a form field class.

See *ModelForm factory function* for example usage.

You must provide the list of fields explicitly, either via keyword arguments `fields` or `exclude`, or the corresponding attributes on the form's inner `Meta` class. See *Selecting the fields to use* for more information. Omitting any definition of the fields to use will result in an `ImproperlyConfigured` exception.

The `field_classes` keyword argument was added.

### `modelformset_factory`

**modelformset\_factory** (*model*, *form=ModelForm*, *formfield\_callback=None*, *formset=BaseModelFormSet*, *extra=1*, *can\_delete=False*, *can\_order=False*, *max\_num=None*, *fields=None*, *exclude=None*, *widgets=None*, *validate\_max=False*, *localized\_fields=None*, *labels=None*, *help\_texts=None*, *error\_messages=None*, *min\_num=None*, *validate\_min=False*, *field\_classes=None*)

Returns a `FormSet` class for the given `model` class.

Arguments `model`, `form`, `fields`, `exclude`, `formfield_callback`, `widgets`, `localized_fields`, `labels`, `help_texts`, `error_messages`, and `field_classes` are all passed through to `modelform_factory()`.

Arguments `formset`, `extra`, `max_num`, `can_order`, `can_delete` and `validate_max` are passed through to `formset_factory()`. See *formsets* for details.

See *Model formsets* for example usage.

The `field_classes` keyword argument was added.

### `inlineformset_factory`

**inlineformset\_factory** (*parent\_model*, *model*, *form=ModelForm*, *formset=BaseInlineFormSet*, *fk\_name=None*, *fields=None*, *exclude=None*, *extra=3*, *can\_order=False*, *can\_delete=True*, *max\_num=None*, *formfield\_callback=None*, *widgets=None*, *validate\_max=False*, *localized\_fields=None*, *labels=None*, *help\_texts=None*, *error\_messages=None*, *min\_num=None*, *validate\_min=False*, *field\_classes=None*)

Returns an `InlineFormSet` using `modelformset_factory()` with defaults of `formset=BaseInlineFormSet`, `can_delete=True`, and `extra=3`.

If your model has more than one `ForeignKey` to the `parent_model`, you must specify a `fk_name`.

See *Inline formsets* for example usage.

The `field_classes` keyword argument was added.

## 6.12.4 Formset Functions

Formset API reference. For introductory material about formsets, see the *Formsets* topic guide.

### `formset_factory`

**formset\_factory** (*form*, *formset=BaseFormSet*, *extra=1*, *can\_order=False*, *can\_delete=False*, *max\_num=None*, *validate\_max=False*, *min\_num=None*, *validate\_min=False*)

Returns a `FormSet` class for the given `form` class.

See *formsets* for example usage.

## 6.12.5 Widgets

A widget is Django's representation of an HTML input element. The widget handles the rendering of the HTML, and the extraction of data from a GET/POST dictionary that corresponds to the widget.

---

**Tip:** Widgets should not be confused with the *form fields*. Form fields deal with the logic of input validation and are used directly in templates. Widgets deal with rendering of HTML form input elements on the web page and extraction of raw submitted data. However, widgets do need to be *assigned* to form fields.

---

## Specifying widgets

Whenever you specify a field on a form, Django will use a default widget that is appropriate to the type of data that is to be displayed. To find which widget is used on which field, see the documentation about *Built-in Field classes*.

However, if you want to use a different widget for a field, you can just use the *widget* argument on the field definition. For example:

```
from django import forms

class CommentForm(forms.Form):
    name = forms.CharField()
    url = forms.URLField()
    comment = forms.CharField(widget=forms.Textarea)
```

This would specify a form with a comment that uses a larger *Textarea* widget, rather than the default *TextInput* widget.

## Setting arguments for widgets

Many widgets have optional extra arguments; they can be set when defining the widget on the field. In the following example, the *years* attribute is set for a *SelectDateWidget*:

```
from django import forms

BIRTH_YEAR_CHOICES = ('1980', '1981', '1982')
FAVORITE_COLORS_CHOICES = (
    ('blue', 'Blue'),
    ('green', 'Green'),
    ('black', 'Black'),
)

class SimpleForm(forms.Form):
    birth_year = forms.DateField(widget=forms.SelectDateWidget (years=BIRTH_YEAR_
↵CHOICES))
    favorite_colors = forms.MultipleChoiceField(
        required=False,
        widget=forms.CheckboxSelectMultiple,
        choices=FAVORITE_COLORS_CHOICES,
    )
```

See the *Built-in widgets* for more information about which widgets are available and which arguments they accept.

## Widgets inheriting from the Select widget

Widgets inheriting from the *Select* widget deal with choices. They present the user with a list of options to choose from. The different widgets present this choice differently; the *Select* widget itself uses a `<select>` HTML list representation, while *RadioSelect* uses radio buttons.

`Select` widgets are used by default on `ChoiceField` fields. The choices displayed on the widget are inherited from the `ChoiceField` and changing `ChoiceField.choices` will update `Select.choices`. For example:

```
>>> from django import forms
>>> CHOICES = (('1', 'First',), ('2', 'Second',))
>>> choice_field = forms.ChoiceField(widget=forms.RadioSelect, choices=CHOICES)
>>> choice_field.choices
[('1', 'First'), ('2', 'Second')]
>>> choice_field.widget.choices
[('1', 'First'), ('2', 'Second')]
>>> choice_field.widget.choices = ()
>>> choice_field.choices = (('1', 'First and only',),)
>>> choice_field.widget.choices
[('1', 'First and only')]
```

Widgets which offer a `choices` attribute can however be used with fields which are not based on choice – such as a `CharField` – but it is recommended to use a `ChoiceField`-based field when the choices are inherent to the model and not just the representational widget.

## Customizing widget instances

When Django renders a widget as HTML, it only renders very minimal markup - Django doesn't add class names, or any other widget-specific attributes. This means, for example, that all `TextInput` widgets will appear the same on your Web pages.

There are two ways to customize widgets: *per widget instance* and *per widget class*.

## Styling widget instances

If you want to make one widget instance look different from another, you will need to specify additional attributes at the time when the widget object is instantiated and assigned to a form field (and perhaps add some rules to your CSS files).

For example, take the following simple form:

```
from django import forms

class CommentForm(forms.Form):
    name = forms.CharField()
    url = forms.URLField()
    comment = forms.CharField()
```

This form will include three default `TextInput` widgets, with default rendering – no CSS class, no extra attributes. This means that the input boxes provided for each widget will be rendered exactly the same:

```
>>> f = CommentForm(auto_id=False)
>>> f.as_table()
<tr><th>Name:</th><td><input type="text" name="name" required /></td></tr>
<tr><th>Url:</th><td><input type="url" name="url" required /></td></tr>
<tr><th>Comment:</th><td><input type="text" name="comment" required /></td></tr>
```

On a real Web page, you probably don't want every widget to look the same. You might want a larger input element for the comment, and you might want the 'name' widget to have some special CSS class. It is also possible to specify the 'type' attribute to take advantage of the new HTML5 input types. To do this, you use the `Widget.attrs` argument when creating the widget:

```
class CommentForm(forms.Form):
    name = forms.CharField(widget=forms.TextInput(attrs={'class': 'special'}))
    url = forms.URLField()
    comment = forms.CharField(widget=forms.TextInput(attrs={'size': '40'}))
```

Django will then include the extra attributes in the rendered output:

```
>>> f = CommentForm(auto_id=False)
>>> f.as_table()
<tr><th>Name:</th><td><input type="text" name="name" class="special" required /></td>
↪</tr>
<tr><th>Url:</th><td><input type="url" name="url" required /></td></tr>
<tr><th>Comment:</th><td><input type="text" name="comment" size="40" required /></td>
↪</tr>
```

You can also set the HTML `id` using `attrs`. See `BoundField.id_for_label` for an example.

## Styling widget classes

With widgets, it is possible to add assets (css and javascript) and more deeply customize their appearance and behavior.

In a nutshell, you will need to subclass the widget and either *define a “Media” inner class* or *create a “media” property*.

These methods involve somewhat advanced Python programming and are described in detail in the *Form Assets* topic guide.

## Base widget classes

Base widget classes `Widget` and `MultiWidget` are subclassed by all the *built-in widgets* and may serve as a foundation for custom widgets.

### Widget

**class `Widget`** (*attrs=None*)

This abstract class cannot be rendered, but provides the basic attribute `attrs`. You may also implement or override the `render()` method on custom widgets.

#### **attrs**

A dictionary containing HTML attributes to be set on the rendered widget.

```
>>> from django import forms
>>> name = forms.TextInput(attrs={'size': 10, 'title': 'Your name',})
>>> name.render('name', 'A name')
'<input title="Your name" type="text" name="name" value="A name" size="10"
↪required />'
```

If you assign a value of `True` or `False` to an attribute, it will be rendered as an HTML5 boolean attribute:

```
>>> name = forms.TextInput(attrs={'required': True})
>>> name.render('name', 'A name')
'<input name="name" type="text" value="A name" required />'
>>>
```

```
>>> name = forms.TextInput(attrs={'required': False})
>>> name.render('name', 'A name')
'<input name="name" type="text" value="A name" />'
```

**supports\_microseconds**

An attribute that defaults to `True`. If set to `False`, the microseconds part of `datetime` and `time` values will be set to 0.

In older versions, this attribute was only defined on the date and time widgets (as `False`).

**format\_value** (*value*)

Cleans and returns a value for use in the widget template. `value` isn't guaranteed to be valid input, therefore subclass implementations should program defensively.

In older versions, this method is a private API named `_format_value()`. The old name will work until Django 2.0.

**id\_for\_label** (*self, id\_*)

Returns the HTML ID attribute of this widget for use by a `<label>`, given the ID of the field. Returns `None` if an ID isn't available.

This hook is necessary because some widgets have multiple HTML elements and, thus, multiple IDs. In that case, this method should return an ID value that corresponds to the first ID in the widget's tags.

**render** (*name, value, attrs=None*)

Returns HTML for the widget, as a Unicode string. This method must be implemented by the subclass, otherwise `NotImplementedError` will be raised.

The 'value' given is not guaranteed to be valid input, therefore subclass implementations should program defensively.

**value\_from\_datadict** (*data, files, name*)

Given a dictionary of data and this widget's name, returns the value of this widget. `files` may contain data coming from `request.FILES`. Returns `None` if a value wasn't provided. Note also that `value_from_datadict` may be called more than once during handling of form data, so if you customize it and add expensive processing, you should implement some caching mechanism yourself.

**value\_omitted\_from\_data** (*data, files, name*)

Given `data` and `files` dictionaries and this widget's name, returns whether or not there's data or files for the widget.

The method's result affects whether or not a field in a model form *falls back to its default*.

Special cases are `CheckboxInput`, `CheckboxSelectMultiple`, and `SelectMultiple`, which always return `False` because an unchecked checkbox and unselected `<select multiple>` don't appear in the data of an HTML form submission, so it's unknown whether or not the user submitted a value.

**use\_required\_attribute** (*initial*)

Given a form field's `initial` value, returns whether or not the widget can be rendered with the required HTML attribute. Forms use this method along with `Field.required` and `Form.use_required_attribute` to determine whether or not to display the required attribute for each field.

By default, returns `False` for hidden widgets and `True` otherwise. Special cases are `ClearableFileInput`, which returns `False` when `initial` is not set, and `CheckboxSelectMultiple`, which always returns `False` because browser validation would require all checkboxes to be checked instead of at least one.

Override this method in custom widgets that aren't compatible with browser validation. For example, a WYSIWYG text editor widget backed by a hidden `textarea` element may want to always return `False` to avoid browser validation on the hidden field.

## MultiWidget

**class MultiWidget** (*widgets, attrs=None*)

A widget that is composed of multiple widgets. `MultiWidget` works hand in hand with the `MultiValueField`.

`MultiWidget` has one required argument:

### **widgets**

An iterable containing the widgets needed.

And one required method:

### **decompress** (*value*)

This method takes a single “compressed” value from the field and returns a list of “decompressed” values. The input value can be assumed valid, but not necessarily non-empty.

This method **must be implemented** by the subclass, and since the value may be empty, the implementation must be defensive.

The rationale behind “decompression” is that it is necessary to “split” the combined value of the form field into the values for each widget.

An example of this is how `SplitDateTimeWidget` turns a `datetime` value into a list with date and time split into two separate values:

```
from django.forms import MultiWidget

class SplitDateTimeWidget(MultiWidget):

    # ...

    def decompress(self, value):
        if value:
            return [value.date(), value.time().replace(microsecond=0)]
        return [None, None]
```

**Tip:** Note that `MultiValueField` has a complementary method `compress()` with the opposite responsibility - to combine cleaned values of all member fields into one.

Other methods that may be useful to override include:

**render** (*name, value, attrs=None*)

Argument `value` is handled differently in this method from the subclasses of `Widget` because it has to figure out how to split a single value for display in multiple widgets.

The `value` argument used when rendering can be one of two things:

- A list.
- A single value (e.g., a string) that is the “compressed” representation of a list of values.

If `value` is a list, the output of `render()` will be a concatenation of rendered child widgets. If `value` is not a list, it will first be processed by the method `decompress()` to create the list and then rendered.

When `render()` executes its HTML rendering, each value in the list is rendered with the corresponding widget – the first value is rendered in the first widget, the second value is rendered in the second widget, etc.

Unlike in the single value widgets, method `render()` need not be implemented in the subclasses.

**`format_output`** (*rendered\_widgets*)

Given a list of rendered widgets (as strings), returns a Unicode string representing the HTML for the whole lot.

This hook allows you to format the HTML design of the widgets any way you'd like.

Here's an example widget which subclasses `MultiWidget` to display a date with the day, month, and year in different select boxes. This widget is intended to be used with a `DateField` rather than a `MultiValueField`, thus we have implemented `value_from_datadict()`:

```
from datetime import date
from django.forms import widgets

class DateSelectorWidget(widgets.MultiWidget):
    def __init__(self, attrs=None):
        # create choices for days, months, years
        # example below, the rest snipped for brevity.
        years = [(year, year) for year in (2011, 2012, 2013)]
        _widgets = (
            widgets.Select(attrs=attrs, choices=days),
            widgets.Select(attrs=attrs, choices=months),
            widgets.Select(attrs=attrs, choices=years),
        )
        super(DateSelectorWidget, self).__init__(_widgets, attrs)

    def decompress(self, value):
        if value:
            return [value.day, value.month, value.year]
        return [None, None, None]

    def format_output(self, rendered_widgets):
        return ''.join(rendered_widgets)

    def value_from_datadict(self, data, files, name):
        datelist = [
            widget.value_from_datadict(data, files, name + '_%s' % i)
            for i, widget in enumerate(self.widgets)
        ]
        try:
            D = date(
                day=int(datelist[0]),
                month=int(datelist[1]),
                year=int(datelist[2]),
            )
        except ValueError:
            return ''
        else:
            return str(D)
```

The constructor creates several `Select` widgets in a tuple. The super class uses this tuple to setup the widget.

The `format_output()` method is fairly vanilla here (in fact, it's the same as what's been implemented as the default for `MultiWidget`), but the idea is that you could add custom HTML between the widgets should you wish.

The required method `decompress()` breaks up a `datetime.date` value into the day, month, and year values corresponding to each widget. Note how the method handles the case where `value` is `None`.

The default implementation of `value_from_datadict()` returns a list of values corresponding to each `Widget`. This is appropriate when using a `MultiWidget` with a `MultiValueField`, but since we want to use this widget with a `DateField` which takes a single value, we have overridden this method to combine the data of all the subwidgets into a `datetime.date`. The method extracts data from the `POST` dictionary and constructs and validates the date. If it is valid, we return the string, otherwise, we return an empty string which will cause `form.is_valid` to return `False`.

## Built-in widgets

Django provides a representation of all the basic HTML widgets, plus some commonly used groups of widgets in the `django.forms.widgets` module, including *the input of text, various checkboxes and selectors, uploading files, and handling of multi-valued input*.

### Widgets handling input of text

These widgets make use of the HTML elements `input` and `textarea`.

#### Text Input

##### class `TextInput`

Text input: `<input type="text" ...>`

#### NumberInput

##### class `NumberInput`

Text input: `<input type="number" ...>`

Beware that not all browsers support entering localized numbers in `number` input types. Django itself avoids using them for fields having their `localize` property set to `True`.

#### EmailInput

##### class `EmailInput`

Text input: `<input type="email" ...>`

#### URLInput

##### class `URLInput`

Text input: `<input type="url" ...>`

#### PasswordInput

##### class `PasswordInput`

Password input: `<input type='password' ...>`

Takes one optional argument:

**render\_value**

Determines whether the widget will have a value filled in when the form is re-displayed after a validation error (default is `False`).

**HiddenInput**

**class HiddenInput**

Hidden input: `<input type='hidden' ...>`

Note that there also is a *MultipleHiddenInput* widget that encapsulates a set of hidden input elements.

**DateInput**

**class DateInput**

Date input as a simple text box: `<input type='text' ...>`

Takes same arguments as *TextInput*, with one more optional argument:

**format**

The format in which this field's initial value will be displayed.

If no `format` argument is provided, the default format is the first format found in *DATE\_INPUT\_FORMATS* and respects *Format localization*.

**DateTimeInput**

**class DateTimeInput**

Date/time input as a simple text box: `<input type='text' ...>`

Takes same arguments as *TextInput*, with one more optional argument:

**format**

The format in which this field's initial value will be displayed.

If no `format` argument is provided, the default format is the first format found in *DATETIME\_INPUT\_FORMATS* and respects *Format localization*.

By default, the microseconds part of the time value is always set to 0. If microseconds are required, use a subclass with the *supports\_microseconds* attribute set to `True`.

**TimeInput**

**class TimeInput**

Time input as a simple text box: `<input type='text' ...>`

Takes same arguments as *TextInput*, with one more optional argument:

**format**

The format in which this field's initial value will be displayed.

If no `format` argument is provided, the default format is the first format found in *TIME\_INPUT\_FORMATS* and respects *Format localization*.

For the treatment of microseconds, see *DateTimeInput*.

## Textarea

### class Textarea

Text area: `<textarea>...</textarea>`

## Selector and checkbox widgets

### CheckboxInput

#### class CheckboxInput

Checkbox: `<input type='checkbox' ...>`

Takes one optional argument:

#### check\_test

A callable that takes the value of the `CheckboxInput` and returns `True` if the checkbox should be checked for that value.

## Select

### class Select

Select widget: `<select><option ...>...</select>`

#### choices

This attribute is optional when the form field does not have a `choices` attribute. If it does, it will override anything you set here when the attribute is updated on the *Field*.

## NullBooleanSelect

### class NullBooleanSelect

Select widget with options 'Unknown', 'Yes' and 'No'

## SelectMultiple

### class SelectMultiple

Similar to *Select*, but allows multiple selection: `<select multiple='multiple'>...</select>`

## RadioSelect

### class RadioSelect

Similar to *Select*, but rendered as a list of radio buttons within `<li>` tags:

```
<ul>
  <li><input type='radio' name='...'></li>
  ...
</ul>
```

For more granular control over the generated markup, you can loop over the radio buttons in the template. Assuming a form `myform` with a field `beatles` that uses a `RadioSelect` as its widget:

```
{% for radio in myform.beatles %}
<div class="myradio">
    {{ radio }}
</div>
{% endfor %}
```

This would generate the following HTML:

```
<div class="myradio">
  <label for="id_beatles_0"><input id="id_beatles_0" name="beatles" type="radio"
  ↪ value="john" required /> John</label>
</div>
<div class="myradio">
  <label for="id_beatles_1"><input id="id_beatles_1" name="beatles" type="radio"
  ↪ value="paul" required /> Paul</label>
</div>
<div class="myradio">
  <label for="id_beatles_2"><input id="id_beatles_2" name="beatles" type="radio"
  ↪ value="george" required /> George</label>
</div>
<div class="myradio">
  <label for="id_beatles_3"><input id="id_beatles_3" name="beatles" type="radio"
  ↪ value="ringo" required /> Ringo</label>
</div>
```

That included the `<label>` tags. To get more granular, you can use each radio button's `tag`, `choice_label` and `id_for_label` attributes. For example, this template...

```
{% for radio in myform.beatles %}
  <label for="{{ radio.id_for_label }}">
    {{ radio.choice_label }}
    <span class="radio">{{ radio.tag }}</span>
  </label>
{% endfor %}
```

...will result in the following HTML:

```
<label for="id_beatles_0">
  John
  <span class="radio"><input id="id_beatles_0" name="beatles" type="radio"
  ↪ value="john" required /></span>
</label>

<label for="id_beatles_1">
  Paul
  <span class="radio"><input id="id_beatles_1" name="beatles" type="radio"
  ↪ value="paul" required /></span>
</label>

<label for="id_beatles_2">
  George
  <span class="radio"><input id="id_beatles_2" name="beatles" type="radio"
  ↪ value="george" required /></span>
</label>

<label for="id_beatles_3">
  Ringo
  <span class="radio"><input id="id_beatles_3" name="beatles" type="radio"
  ↪ value="ringo" required /></span>
```

```
</label>
```

If you decide not to loop over the radio buttons – e.g., if your template simply includes `{{ myform.beatles }}` – they’ll be output in a `<ul>` with `<li>` tags, as above.

The outer `<ul>` container receives the `id` attribute of the widget, if defined, or `BoundField.auto_id` otherwise.

When looping over the radio buttons, the `label` and `input` tags include `for` and `id` attributes, respectively. Each radio button has an `id_for_label` attribute to output the element’s ID.

## CheckboxSelectMultiple

### class `CheckboxSelectMultiple`

Similar to `SelectMultiple`, but rendered as a list of check buttons:

```
<ul>
  <li><input type='checkbox' name='...' ></li>
  ...
</ul>
```

The outer `<ul>` container receives the `id` attribute of the widget, if defined, or `BoundField.auto_id` otherwise.

Like `RadioSelect`, you can loop over the individual checkboxes for the widget’s choices. Unlike `RadioSelect`, the checkboxes won’t include the `required` HTML attribute if the field is required because browser validation would require all checkboxes to be checked instead of at least one.

When looping over the checkboxes, the `label` and `input` tags include `for` and `id` attributes, respectively. Each checkbox has an `id_for_label` attribute to output the element’s ID.

## File upload widgets

### FileInput

#### class `FileInput`

File upload input: `<input type='file' ...>`

### ClearableFileInput

#### class `ClearableFileInput`

File upload input: `<input type='file' ...>`, with an additional checkbox input to clear the field’s value, if the field is not required and has initial data.

## Composite widgets

### MultipleHiddenInput

#### class `MultipleHiddenInput`

Multiple `<input type='hidden' ...>` widgets.

A widget that handles multiple hidden widgets for fields that have a list of values.

**choices**

This attribute is optional when the form field does not have a `choices` attribute. If it does, it will override anything you set here when the attribute is updated on the *Field*.

**SplitDateTimeWidget****class SplitDateTimeWidget**

Wrapper (using *MultiWidget*) around two widgets: *DateInput* for the date, and *TimeInput* for the time. Must be used with *SplitDateTimeField* rather than *DateTimeField*.

*SplitDateTimeWidget* has two optional attributes:

**date\_format**

Similar to *DateInput.format*

**time\_format**

Similar to *TimeInput.format*

**SplitHiddenDateTimeWidget****class SplitHiddenDateTimeWidget**

Similar to *SplitDateTimeWidget*, but uses *HiddenInput* for both date and time.

**SelectDateWidget****class SelectDateWidget**

Wrapper around three *Select* widgets: one each for month, day, and year.

Takes several optional arguments:

**years**

An optional list/tuple of years to use in the “year” select box. The default is a list containing the current year and the next 9 years.

**months**

An optional dict of months to use in the “months” select box.

The keys of the dict correspond to the month number (1-indexed) and the values are the displayed months:

```
MONTHS = {
    1:_('jan'), 2:_('feb'), 3:_('mar'), 4:_('apr'),
    5:_('may'), 6:_('jun'), 7:_('jul'), 8:_('aug'),
    9:_('sep'), 10:_('oct'), 11:_('nov'), 12:_('dec')
}
```

**empty\_label**

If the *DateField* is not required, *SelectDateWidget* will have an empty choice at the top of the list (which is --- by default). You can change the text of this label with the `empty_label` attribute. `empty_label` can be a string, list, or tuple. When a string is used, all select boxes will each have an empty choice with this label. If `empty_label` is a list or tuple of 3 string elements, the select boxes will have their own custom label. The labels should be in this order ('year\_label', 'month\_label', 'day\_label').

```
# A custom empty label with string
field1 = forms.DateField(widget=SelectDateWidget(empty_label="Nothing"))

# A custom empty label with tuple
field1 = forms.DateField(
    widget=SelectDateWidget(
        empty_label=("Choose Year", "Choose Month", "Choose Day"),
    ),
)
```

This widget used to be located in the `django.forms.extras.widgets` package. It is now defined in `django.forms.widgets` and like the other widgets it can be imported directly from `django.forms`.

## 6.12.6 Form and field validation

Form validation happens when the data is cleaned. If you want to customize this process, there are various places to make changes, each one serving a different purpose. Three types of cleaning methods are run during form processing. These are normally executed when you call the `is_valid()` method on a form. There are other things that can also trigger cleaning and validation (accessing the `errors` attribute or calling `full_clean()` directly), but normally they won't be needed.

In general, any cleaning method can raise `ValidationError` if there is a problem with the data it is processing, passing the relevant information to the `ValidationError` constructor. *See below* for the best practice in raising `ValidationError`. If no `ValidationError` is raised, the method should return the cleaned (normalized) data as a Python object.

Most validation can be done using *validators* - simple helpers that can be reused easily. Validators are simple functions (or callables) that take a single argument and raise `ValidationError` on invalid input. Validators are run after the field's `to_python` and `validate` methods have been called.

Validation of a form is split into several steps, which can be customized or overridden:

- The `to_python()` method on a `Field` is the first step in every validation. It coerces the value to a correct datatype and raises `ValidationError` if that is not possible. This method accepts the raw value from the widget and returns the converted value. For example, a `FloatField` will turn the data into a Python `float` or raise a `ValidationError`.
- The `validate()` method on a `Field` handles field-specific validation that is not suitable for a validator. It takes a value that has been coerced to a correct datatype and raises `ValidationError` on any error. This method does not return anything and shouldn't alter the value. You should override it to handle validation logic that you can't or don't want to put in a validator.
- The `run_validators()` method on a `Field` runs all of the field's validators and aggregates all the errors into a single `ValidationError`. You shouldn't need to override this method.
- The `clean()` method on a `Field` subclass is responsible for running `to_python()`, `validate()`, and `run_validators()` in the correct order and propagating their errors. If, at any time, any of the methods raise `ValidationError`, the validation stops and that error is raised. This method returns the clean data, which is then inserted into the `cleaned_data` dictionary of the form.
- The `clean_<fieldname>()` method is called on a form subclass - where `<fieldname>` is replaced with the name of the form field attribute. This method does any cleaning that is specific to that particular attribute, unrelated to the type of field that it is. This method is not passed any parameters. You will need to look up the value of the field in `self.cleaned_data` and remember that it will be a Python object at this point, not the original string submitted in the form (it will be in `cleaned_data` because the general field `clean()` method, above, has already cleaned the data once).

For example, if you wanted to validate that the contents of a `CharField` called `serialnumber` was unique, `clean_serialnumber()` would be the right place to do this. You don't need a specific field (it's just a `CharField`), but you want a formfield-specific piece of validation and, possibly, cleaning/normalizing the data.

The return value of this method replaces the existing value in `cleaned_data`, so it must be the field's value from `cleaned_data` (even if this method didn't change it) or a new cleaned value.

- The form subclass's `clean()` method can perform validation that requires access to multiple form fields. This is where you might put in checks such as “if field A is supplied, field B must contain a valid email address”. This method can return a completely different dictionary if it wishes, which will be used as the `cleaned_data`.

Since the field validation methods have been run by the time `clean()` is called, you also have access to the form's `errors` attribute which contains all the errors raised by cleaning of individual fields.

Note that any errors raised by your `Form.clean()` override will not be associated with any field in particular. They go into a special “field” (called `__all__`), which you can access via the `non_field_errors()` method if you need to. If you want to attach errors to a specific field in the form, you need to call `add_error()`.

Also note that there are special considerations when overriding the `clean()` method of a `ModelForm` subclass. (see the [ModelForm documentation](#) for more information)

These methods are run in the order given above, one field at a time. That is, for each field in the form (in the order they are declared in the form definition), the `Field.clean()` method (or its override) is run, then `clean_<fieldname>()`. Finally, once those two methods are run for every field, the `Form.clean()` method, or its override, is executed whether or not the previous methods have raised errors.

Examples of each of these methods are provided below.

As mentioned, any of these methods can raise a `ValidationError`. For any field, if the `Field.clean()` method raises a `ValidationError`, any field-specific cleaning method is not called. However, the cleaning methods for all remaining fields are still executed.

## Raising `ValidationError`

In order to make error messages flexible and easy to override, consider the following guidelines:

- Provide a descriptive error code to the constructor:

```
# Good
ValidationError(_('Invalid value'), code='invalid')

# Bad
ValidationError(_('Invalid value'))
```

- Don't coerce variables into the message; use placeholders and the `params` argument of the constructor:

```
# Good
ValidationError(
    _('Invalid value: %(value)s'),
    params={'value': '42'},
)

# Bad
ValidationError(_('Invalid value: %s') % value)
```

- Use mapping keys instead of positional formatting. This enables putting the variables in any order or omitting them altogether when rewriting the message:

```
# Good
ValidationError(
    _('Invalid value: %(value)s'),
    params={'value': '42'},
)

# Bad
ValidationError(
    _('Invalid value: %s'),
    params=('42',),
)
```

- Wrap the message with `gettext` to enable translation:

```
# Good
ValidationError(_('Invalid value'))

# Bad
ValidationError('Invalid value')
```

Putting it all together:

```
raise ValidationError(
    _('Invalid value: %(value)s'),
    code='invalid',
    params={'value': '42'},
)
```

Following these guidelines is particularly necessary if you write reusable forms, form fields, and model fields.

While not recommended, if you are at the end of the validation chain (i.e. your form `clean()` method) and you know you will *never* need to override your error message you can still opt for the less verbose:

```
ValidationError(_('Invalid value: %s') % value)
```

The `Form.errors.as_data()` and `Form.errors.as_json()` methods greatly benefit from fully featured `ValidationErrors` (with a code name and a `params` dictionary).

## Raising multiple errors

If you detect multiple errors during a cleaning method and wish to signal all of them to the form submitter, it is possible to pass a list of errors to the `ValidationError` constructor.

As above, it is recommended to pass a list of `ValidationError` instances with `codes` and `params` but a list of strings will also work:

```
# Good
raise ValidationError([
    ValidationError(_('Error 1'), code='error1'),
    ValidationError(_('Error 2'), code='error2'),
])

# Bad
raise ValidationError([
    _('Error 1'),
    _('Error 2'),
])
```

## Using validation in practice

The previous sections explained how validation works in general for forms. Since it can sometimes be easier to put things into place by seeing each feature in use, here are a series of small examples that use each of the previous features.

### Using validators

Django's form (and model) fields support use of simple utility functions and classes known as validators. A validator is merely a callable object or function that takes a value and simply returns nothing if the value is valid or raises a `ValidationError` if not. These can be passed to a field's constructor, via the field's `validators` argument, or defined on the `Field` class itself with the `default_validators` attribute.

Simple validators can be used to validate values inside the field, let's have a look at Django's `SlugField`:

```
from django.forms import CharField
from django.core import validators

class SlugField(CharField):
    default_validators = [validators.validate_slug]
```

As you can see, `SlugField` is just a `CharField` with a customized validator that validates that submitted text obeys to some character rules. This can also be done on field definition so:

```
slug = forms.SlugField()
```

is equivalent to:

```
slug = forms.CharField(validators=[validators.validate_slug])
```

Common cases such as validating against an email or a regular expression can be handled using existing validator classes available in Django. For example, `validators.validate_slug` is an instance of a `RegexValidator` constructed with the first argument being the pattern: `^[-a-zA-Z0-9_]+$. See the section on writing validators to see a list of what is already available and for an example of how to write a validator.`

### Form field default cleaning

Let's first create a custom form field that validates its input is a string containing comma-separated email addresses. The full class looks like this:

```
from django import forms
from django.core.validators import validate_email

class MultiEmailField(forms.Field):
    def to_python(self, value):
        """Normalize data to a list of strings."""
        # Return an empty list if no input was given.
        if not value:
            return []
        return value.split(',')

    def validate(self, value):
        """Check if value consists only of valid emails."""
        # Use the parent's handling of required fields, etc.
        super(MultiEmailField, self).validate(value)
```

```
for email in value:
    validate_email(email)
```

Every form that uses this field will have these methods run before anything else can be done with the field's data. This is cleaning that is specific to this type of field, regardless of how it is subsequently used.

Let's create a simple `ContactForm` to demonstrate how you'd use this field:

```
class ContactForm(forms.Form):
    subject = forms.CharField(max_length=100)
    message = forms.CharField()
    sender = forms.EmailField()
    recipients = MultiEmailField()
    cc_myself = forms.BooleanField(required=False)
```

Simply use `MultiEmailField` like any other form field. When the `is_valid()` method is called on the form, the `MultiEmailField.clean()` method will be run as part of the cleaning process and it will, in turn, call the custom `to_python()` and `validate()` methods.

### Cleaning a specific field attribute

Continuing on from the previous example, suppose that in our `ContactForm`, we want to make sure that the `recipients` field always contains the address `"fred@example.com"`. This is validation that is specific to our form, so we don't want to put it into the general `MultiEmailField` class. Instead, we write a cleaning method that operates on the `recipients` field, like so:

```
from django import forms

class ContactForm(forms.Form):
    # Everything as before.
    ...

    def clean_recipients(self):
        data = self.cleaned_data['recipients']
        if "fred@example.com" not in data:
            raise forms.ValidationError("You have forgotten about Fred!")

        # Always return a value to use as the new cleaned data, even if
        # this method didn't change it.
        return data
```

### Cleaning and validating fields that depend on each other

Suppose we add another requirement to our contact form: if the `cc_myself` field is `True`, the `subject` must contain the word `"help"`. We are performing validation on more than one field at a time, so the form's `clean()` method is a good spot to do this. Notice that we are talking about the `clean()` method on the form here, whereas earlier we were writing a `clean()` method on a field. It's important to keep the field and form difference clear when working out where to validate things. Fields are single data points, forms are a collection of fields.

By the time the form's `clean()` method is called, all the individual field clean methods will have been run (the previous two sections), so `self.cleaned_data` will be populated with any data that has survived so far. So you also need to remember to allow for the fact that the fields you are wanting to validate might not have survived the initial individual field checks.

There are two ways to report any errors from this step. Probably the most common method is to display the error at the top of the form. To create such an error, you can raise a `ValidationError` from the `clean()` method. For example:

```
from django import forms

class ContactForm(forms.Form):
    # Everything as before.
    ...

    def clean(self):
        cleaned_data = super(ContactForm, self).clean()
        cc_myself = cleaned_data.get("cc_myself")
        subject = cleaned_data.get("subject")

        if cc_myself and subject:
            # Only do something if both fields are valid so far.
            if "help" not in subject:
                raise forms.ValidationError(
                    "Did not send for 'help' in the subject despite "
                    "CC'ing yourself."
                )
```

In this code, if the validation error is raised, the form will display an error message at the top of the form (normally) describing the problem.

The call to `super(ContactForm, self).clean()` in the example code ensures that any validation logic in parent classes is maintained. If your form inherits another that doesn't return a `cleaned_data` dictionary in its `clean()` method (doing so is optional), then don't assign `cleaned_data` to the result of the `super()` call and use `self.cleaned_data` instead:

```
def clean(self):
    super(ContactForm, self).clean()
    cc_myself = self.cleaned_data.get("cc_myself")
    ...
```

The second approach for reporting validation errors might involve assigning the error message to one of the fields. In this case, let's assign an error message to both the "subject" and "cc\_myself" rows in the form display. Be careful when doing this in practice, since it can lead to confusing form output. We're showing what is possible here and leaving it up to you and your designers to work out what works effectively in your particular situation. Our new code (replacing the previous sample) looks like this:

```
from django import forms

class ContactForm(forms.Form):
    # Everything as before.
    ...

    def clean(self):
        cleaned_data = super(ContactForm, self).clean()
        cc_myself = cleaned_data.get("cc_myself")
        subject = cleaned_data.get("subject")

        if cc_myself and subject and "help" not in subject:
            msg = "Must put 'help' in subject when cc'ing yourself."
            self.add_error('cc_myself', msg)
            self.add_error('subject', msg)
```

The second argument of `add_error()` can be a simple string, or preferably an instance of `ValidationError`. See *Raising ValidationError* for more details. Note that `add_error()` automatically removes the field from `cleaned_data`.

## 6.13 Middleware

This document explains all middleware components that come with Django. For information on how to use them and how to write your own middleware, see the *middleware usage guide*.

### 6.13.1 Available middleware

#### Cache middleware

**class UpdateCacheMiddleware**

**class FetchFromCacheMiddleware**

Enable the site-wide cache. If these are enabled, each Django-powered page will be cached for as long as the `CACHE_MIDDLEWARE_SECONDS` setting defines. See the *cache documentation*.

#### “Common” middleware

**class CommonMiddleware**

Adds a few conveniences for perfectionists:

- Forbids access to user agents in the `DISALLOWED_USER_AGENTS` setting, which should be a list of compiled regular expression objects.
- Performs URL rewriting based on the `APPEND_SLASH` and `PREPEND_WWW` settings.

If `APPEND_SLASH` is `True` and the initial URL doesn't end with a slash, and it is not found in the URLconf, then a new URL is formed by appending a slash at the end. If this new URL is found in the URLconf, then Django redirects the request to this new URL. Otherwise, the initial URL is processed as usual.

For example, `foo.com/bar` will be redirected to `foo.com/bar/` if you don't have a valid URL pattern for `foo.com/bar` but *do* have a valid pattern for `foo.com/bar/`.

If `PREPEND_WWW` is `True`, URLs that lack a leading “www.” will be redirected to the same URL with a leading “www.”

Both of these options are meant to normalize URLs. The philosophy is that each URL should exist in one, and only one, place. Technically a URL `foo.com/bar` is distinct from `foo.com/bar/` – a search-engine indexer would treat them as separate URLs – so it's best practice to normalize URLs.

- Handles ETags based on the `USE_ETAGS` setting. If `USE_ETAGS` is set to `True`, Django will calculate an ETag for each request by MD5-hashing the page content, and it'll take care of sending `Not Modified` responses, if appropriate.

`CommonMiddleware.response_redirect_class`

Defaults to `HttpResponsePermanentRedirect`. Subclass `CommonMiddleware` and override the attribute to customize the redirects issued by the middleware.

**class BrokenLinkEmailsMiddleware**

- Sends broken link notification emails to `MANAGERS` (see *Error reporting*).

## Exception middleware

### class `ExceptionMiddleware`

Catches exceptions raised during the request/response cycle and returns the appropriate response.

- `Http404` is processed by `handler404` (or a more friendly debug page if `DEBUG=True`).
- `PermissionDenied` is processed by `handler403`.
- `MultipartParserError` is processed by `handler400`.
- `SuspiciousOperation` is processed by `handler400` (or a more friendly debug page if `DEBUG=True`).
- Any other exception is processed by `handler500` (or a more friendly debug page if `DEBUG=True`).

Django uses this middleware regardless of whether or not you include it in `MIDDLEWARE`, however, you may want to subclass if your own middleware needs to transform any of these exceptions into the appropriate responses. `LocaleMiddleware` does this, for example.

## GZip middleware

### class `GZipMiddleware`

**Warning:** Security researchers recently revealed that when compression techniques (including `GZipMiddleware`) are used on a website, the site may become exposed to a number of possible attacks. Before using `GZipMiddleware` on your site, you should consider very carefully whether you are subject to these attacks. If you're in *any* doubt about whether you're affected, you should avoid using `GZipMiddleware`. For more details, see the [the BREACH paper \(PDF\)](#) and [breachattack.com](#).

Compresses content for browsers that understand GZip compression (all modern browsers).

This middleware should be placed before any other middleware that need to read or write the response body so that compression happens afterward.

It will NOT compress content if any of the following are true:

- The content body is less than 200 bytes long.
- The response has already set the `Content-Encoding` header.
- The request (the browser) hasn't sent an `Accept-Encoding` header containing `gzip`.

You can apply GZip compression to individual views using the `gzip_page()` decorator.

In older versions, Django's CSRF protection mechanism was vulnerable to BREACH attacks when compression was used. This is no longer the case, but you should still take care not to compromise your own secrets this way.

## Conditional GET middleware

### class `ConditionalGetMiddleware`

Handles conditional GET operations. If the response has a `ETag` or `Last-Modified` header, and the request has `If-None-Match` or `If-Modified-Since`, the response is replaced by an `HttpResponseNotModified`.

Also sets the `Date` and `Content-Length` response-headers.

## Locale middleware

### class `LocaleMiddleware`

Enables language selection based on data from the request. It customizes content for each user. See the *internationalization documentation*.

`LocaleMiddleware.response_redirect_class`

Defaults to `HttpResponseRedirect`. Subclass `LocaleMiddleware` and override the attribute to customize the redirects issued by the middleware.

## Message middleware

### class `MessageMiddleware`

Enables cookie- and session-based message support. See the *messages documentation*.

## Security middleware

**Warning:** If your deployment situation allows, it's usually a good idea to have your front-end Web server perform the functionality provided by the `SecurityMiddleware`. That way, if there are requests that aren't served by Django (such as static media or user-uploaded files), they will have the same protections as requests to your Django application.

### class `SecurityMiddleware`

The `django.middleware.security.SecurityMiddleware` provides several security enhancements to the request/response cycle. Each one can be independently enabled or disabled with a setting.

- `SECURE_BROWSER_XSS_FILTER`
- `SECURE_CONTENT_TYPE_NOSNIFF`
- `SECURE_HSTS_INCLUDE_SUBDOMAINS`
- `SECURE_HSTS_SECONDS`
- `SECURE_REDIRECT_EXEMPT`
- `SECURE_SSL_HOST`
- `SECURE_SSL_REDIRECT`

## HTTP Strict Transport Security

For sites that should only be accessed over HTTPS, you can instruct modern browsers to refuse to connect to your domain name via an insecure connection (for a given period of time) by setting the “`Strict-Transport-Security`” header. This reduces your exposure to some SSL-stripping man-in-the-middle (MITM) attacks.

`SecurityMiddleware` will set this header for you on all HTTPS responses if you set the `SECURE_HSTS_SECONDS` setting to a non-zero integer value.

When enabling HSTS, it's a good idea to first use a small value for testing, for example, `SECURE_HSTS_SECONDS = 3600` for one hour. Each time a Web browser sees the HSTS header from your site, it will refuse to communicate non-securely (using HTTP) with your domain for the given period of time. Once you confirm that all assets are served

securely on your site (i.e. HSTS didn't break anything), it's a good idea to increase this value so that infrequent visitors will be protected (31536000 seconds, i.e. 1 year, is common).

Additionally, if you set the `SECURE_HSTS_INCLUDE_SUBDOMAINS` setting to `True`, `SecurityMiddleware` will add the `includeSubDomains` directive to the `Strict-Transport-Security` header. This is recommended (assuming all subdomains are served exclusively using HTTPS), otherwise your site may still be vulnerable via an insecure connection to a subdomain.

**Warning:** The HSTS policy applies to your entire domain, not just the URL of the response that you set the header on. Therefore, you should only use it if your entire domain is served via HTTPS only.

Browsers properly respecting the HSTS header will refuse to allow users to bypass warnings and connect to a site with an expired, self-signed, or otherwise invalid SSL certificate. If you use HSTS, make sure your certificates are in good shape and stay that way!

---

**Note:** If you are deployed behind a load-balancer or reverse-proxy server, and the `Strict-Transport-Security` header is not being added to your responses, it may be because Django doesn't realize that it's on a secure connection; you may need to set the `SECURE_PROXY_SSL_HEADER` setting.

---

#### **X-Content-Type-Options: nosniff**

Some browsers will try to guess the content types of the assets that they fetch, overriding the `Content-Type` header. While this can help display sites with improperly configured servers, it can also pose a security risk.

If your site serves user-uploaded files, a malicious user could upload a specially-crafted file that would be interpreted as HTML or JavaScript by the browser when you expected it to be something harmless.

To learn more about this header and how the browser treats it, you can read about it on the [IE Security Blog](#).

To prevent the browser from guessing the content type and force it to always use the type provided in the `Content-Type` header, you can pass the `X-Content-Type-Options: nosniff` header. `SecurityMiddleware` will do this for all responses if the `SECURE_CONTENT_TYPE_NOSNIFF` setting is `True`.

Note that in most deployment situations where Django isn't involved in serving user-uploaded files, this setting won't help you. For example, if your `MEDIA_URL` is served directly by your front-end Web server (nginx, Apache, etc.) then you'd want to set this header there. On the other hand, if you are using Django to do something like require authorization in order to download files and you cannot set the header using your Web server, this setting will be useful.

#### **X-XSS-Protection: 1; mode=block**

Some browsers have the ability to block content that appears to be an [XSS attack](#). They work by looking for JavaScript content in the GET or POST parameters of a page. If the JavaScript is replayed in the server's response, the page is blocked from rendering and an error page is shown instead.

The `X-XSS-Protection` header is used to control the operation of the XSS filter.

To enable the XSS filter in the browser, and force it to always block suspected XSS attacks, you can pass the `X-XSS-Protection: 1; mode=block` header. `SecurityMiddleware` will do this for all responses if the `SECURE_BROWSER_XSS_FILTER` setting is `True`.

**Warning:** The browser XSS filter is a useful defense measure, but must not be relied upon exclusively. It cannot detect all XSS attacks and not all browsers support the header. Ensure you are still *validating and sanitizing* all input to prevent XSS attacks.

## SSL Redirect

If your site offers both HTTP and HTTPS connections, most users will end up with an unsecured connection by default. For best security, you should redirect all HTTP connections to HTTPS.

If you set the `SECURE_SSL_REDIRECT` setting to `True`, `SecurityMiddleware` will permanently (HTTP 301) redirect all HTTP connections to HTTPS.

---

**Note:** For performance reasons, it's preferable to do these redirects outside of Django, in a front-end load balancer or reverse-proxy server such as `nginx`. `SECURE_SSL_REDIRECT` is intended for the deployment situations where this isn't an option.

---

If the `SECURE_SSL_HOST` setting has a value, all redirects will be sent to that host instead of the originally-requested host.

If there are a few pages on your site that should be available over HTTP, and not redirected to HTTPS, you can list regular expressions to match those URLs in the `SECURE_REDIRECT_EXEMPT` setting.

---

**Note:** If you are deployed behind a load-balancer or reverse-proxy server and Django can't seem to tell when a request actually is already secure, you may need to set the `SECURE_PROXY_SSL_HEADER` setting.

---

## Session middleware

**class `SessionMiddleware`**

Enables session support. See the *session documentation*.

## Site middleware

**class `CurrentSiteMiddleware`**

Adds the `site` attribute representing the current site to every incoming `HttpRequest` object. See the *sites documentation*.

## Authentication middleware

**class `AuthenticationMiddleware`**

Adds the `user` attribute, representing the currently-logged-in user, to every incoming `HttpRequest` object. See *Authentication in Web requests*.

**class `RemoteUserMiddleware`**

Middleware for utilizing Web server provided authentication. See *Authentication using REMOTE\_USER* for usage details.

**class `PersistentRemoteUserMiddleware`**

Middleware for utilizing Web server provided authentication when enabled only on the login page. See *Using REMOTE\_USER on login pages only* for usage details.

### CSRF protection middleware

#### class `CsrfViewMiddleware`

Adds protection against Cross Site Request Forgeries by adding hidden form fields to POST forms and checking requests for the correct value. See the *Cross Site Request Forgery protection documentation*.

### X-Frame-Options middleware

#### class `XFrameOptionsMiddleware`

Simple *clickjacking protection via the X-Frame-Options header*.

## 6.13.2 Middleware ordering

Here are some hints about the ordering of various Django middleware classes:

1. *SecurityMiddleware*

It should go near the top of the list if you're going to turn on the SSL redirect as that avoids running through a bunch of other unnecessary middleware.

2. *UpdateCacheMiddleware*

Before those that modify the Vary header (`SessionMiddleware`, `GZipMiddleware`, `LocaleMiddleware`).

3. *GZipMiddleware*

Before any middleware that may change or use the response body.

After `UpdateCacheMiddleware`: Modifies Vary header.

4. *ConditionalGetMiddleware*

Before `CommonMiddleware`: uses its ETag header when `USE_ETAGS = True`.

5. *SessionMiddleware*

After `UpdateCacheMiddleware`: Modifies Vary header.

6. *LocaleMiddleware*

One of the topmost, after `SessionMiddleware` (uses session data) and `UpdateCacheMiddleware` (modifies Vary header).

7. *CommonMiddleware*

Before any middleware that may change the response (it calculates ETags).

After `GZipMiddleware` so it won't calculate an ETag header on gzipped contents.

Close to the top: it redirects when `APPEND_SLASH` or `PREPEND_WWW` are set to `True`.

8. *CsrfViewMiddleware*

Before any view middleware that assumes that CSRF attacks have been dealt with.

9. *AuthenticationMiddleware*

After `SessionMiddleware`: uses session storage.

10. *MessageMiddleware*

After `SessionMiddleware`: can use session-based storage.

11. *FetchFromCacheMiddleware*

After any middleware that modifies the `Vary` header: that header is used to pick a value for the cache hash-key.

12. *FlatpageFallbackMiddleware*

Should be near the bottom as it's a last-resort type of middleware.

13. *RedirectFallbackMiddleware*

Should be near the bottom as it's a last-resort type of middleware.

## 6.14 Migration Operations

Migration files are composed of one or more `Operations`, objects that declaratively record what the migration should do to your database.

Django also uses these `Operation` objects to work out what your models looked like historically, and to calculate what changes you've made to your models since the last migration so it can automatically write your migrations; that's why they're declarative, as it means Django can easily load them all into memory and run through them without touching the database to work out what your project should look like.

There are also more specialized `Operation` objects which are for things like *data migrations* and for advanced manual database manipulation. You can also write your own `Operation` classes if you want to encapsulate a custom change you commonly make.

If you need an empty migration file to write your own `Operation` objects into, just use `python manage.py makemigrations --empty yourappname`, but be aware that manually adding schema-altering operations can confuse the migration autodetector and make resulting runs of `makemigrations` output incorrect code.

All of the core Django operations are available from the `django.db.migrations.operations` module.

For introductory material, see the *migrations topic guide*.

### 6.14.1 Schema Operations

#### `CreateModel`

**class `CreateModel`** (*name, fields, options=None, bases=None, managers=None*)

Creates a new model in the project history and a corresponding table in the database to match it.

*name* is the model name, as would be written in the `models.py` file.

*fields* is a list of 2-tuples of (`field_name, field_instance`). The field instance should be an unbound field (so just `models.CharField(...)`, rather than a field taken from another model).

*options* is an optional dictionary of values from the model's `Meta` class.

*bases* is an optional list of other classes to have this model inherit from; it can contain both class objects as well as strings in the format `"appname.ModelName"` if you want to depend on another model (so you inherit from the historical version). If it's not supplied, it defaults to just inheriting from the standard `models.Model`.

`managers` takes a list of 2-tuples of `(manager_name, manager_instance)`. The first manager in the list will be the default manager for this model during migrations.

### DeleteModel

```
class DeleteModel(name)
```

Deletes the model from the project history and its table from the database.

### RenameModel

```
class RenameModel(old_name, new_name)
```

Renames the model from an old name to a new one.

You may have to manually add this if you change the model's name and quite a few of its fields at once; to the autodetector, this will look like you deleted a model with the old name and added a new one with a different name, and the migration it creates will lose any data in the old table.

### AlterModelTable

```
class AlterModelTable(name, table)
```

Changes the model's table name (the `db_table` option on the `Meta` subclass).

### AlterUniqueTogether

```
class AlterUniqueTogether(name, unique_together)
```

Changes the model's set of unique constraints (the `unique_together` option on the `Meta` subclass).

### AlterIndexTogether

```
class AlterIndexTogether(name, index_together)
```

Changes the model's set of custom indexes (the `index_together` option on the `Meta` subclass).

### AlterOrderWithRespectTo

```
class AlterOrderWithRespectTo(name, order_with_respect_to)
```

Makes or deletes the `_order` column needed for the `order_with_respect_to` option on the `Meta` subclass.

### AlterModelOptions

```
class AlterModelOptions(name, options)
```

Stores changes to miscellaneous model options (settings on a model's `Meta`) like `permissions` and `verbose_name`. Does not affect the database, but persists these changes for `RunPython` instances to use. `options` should be a dictionary mapping option names to values.

## AlterModelManagers

**class AlterModelManagers** (*name, managers*)

Alters the managers that are available during migrations.

## AddField

**class AddField** (*model\_name, name, field, preserve\_default=True*)

Adds a field to a model. *model\_name* is the model's name, *name* is the field's name, and *field* is an unbound Field instance (the thing you would put in the field declaration in `models.py` - for example, `models.IntegerField(null=True)`).

The `preserve_default` argument indicates whether the field's default value is permanent and should be baked into the project state (`True`), or if it is temporary and just for this migration (`False`) - usually because the migration is adding a non-nullable field to a table and needs a default value to put into existing rows. It does not affect the behavior of setting defaults in the database directly - Django never sets database defaults and always applies them in the Django ORM code.

## RemoveField

**class RemoveField** (*model\_name, name*)

Removes a field from a model.

Bear in mind that when reversed, this is actually adding a field to a model. The operation is reversible (apart from any data loss, which of course is irreversible) if the field is nullable or if it has a default value that can be used to populate the recreated column. If the field is not nullable and does not have a default value, the operation is irreversible.

## AlterField

**class AlterField** (*model\_name, name, field, preserve\_default=True*)

Alters a field's definition, including changes to its type, *null*, *unique*, *db\_column* and other field attributes.

The `preserve_default` argument indicates whether the field's default value is permanent and should be baked into the project state (`True`), or if it is temporary and just for this migration (`False`) - usually because the migration is altering a nullable field to a non-nullable one and needs a default value to put into existing rows. It does not affect the behavior of setting defaults in the database directly - Django never sets database defaults and always applies them in the Django ORM code.

Note that not all changes are possible on all databases - for example, you cannot change a text-type field like `models.TextField()` into a number-type field like `models.IntegerField()` on most databases.

## RenameField

**class RenameField** (*model\_name, old\_name, new\_name*)

Changes a field's name (and, unless *db\_column* is set, its column name).

## 6.14.2 Special Operations

### RunSQL

**class RunSQL** (*sql*, *reverse\_sql*=None, *state\_operations*=None, *hints*=None, *elidable*=False)

Allows running of arbitrary SQL on the database - useful for more advanced features of database backends that Django doesn't support directly, like partial indexes.

*sql*, and *reverse\_sql* if provided, should be strings of SQL to run on the database. On most database backends (all but PostgreSQL), Django will split the SQL into individual statements prior to executing them. This requires installing the `sqlparse` Python library.

You can also pass a list of strings or 2-tuples. The latter is used for passing queries and parameters in the same way as `cursor.execute()`. These three operations are equivalent:

```
migrations.RunSQL("INSERT INTO musician (name) VALUES ('Reinhardt');")
migrations.RunSQL(["INSERT INTO musician (name) VALUES ('Reinhardt');", None])
migrations.RunSQL(["INSERT INTO musician (name) VALUES (%s);", ['Reinhardt']])
```

If you want to include literal percent signs in the query, you have to double them if you are passing parameters.

The *reverse\_sql* queries are executed when the migration is unapplied, so you can reverse the changes done in the forwards queries:

```
migrations.RunSQL(
    ["INSERT INTO musician (name) VALUES (%s);", ['Reinhardt']],
    ["DELETE FROM musician where name=%s;", ['Reinhardt']],
)
```

The *state\_operations* argument is so you can supply operations that are equivalent to the SQL in terms of project state; for example, if you are manually creating a column, you should pass in a list containing an `AddField` operation here so that the autodetector still has an up-to-date state of the model (otherwise, when you next run `makemigrations`, it won't see any operation that adds that field and so will try to run it again). For example:

```
migrations.RunSQL(
    "ALTER TABLE musician ADD COLUMN name varchar(255) NOT NULL;",
    state_operations=[
        migrations.AddField(
            'musician',
            'name',
            models.CharField(max_length=255),
        ),
    ],
)
```

The optional *hints* argument will be passed as `**hints` to the `allow_migrate()` method of database routers to assist them in making routing decisions. See [Hints](#) for more details on database hints.

The optional *elidable* argument determines whether or not the operation will be removed (elided) when *squashing migrations*.

#### RunSQL.noop

Pass the `RunSQL.noop` attribute to *sql* or *reverse\_sql* when you want the operation not to do anything in the given direction. This is especially useful in making the operation reversible.

The *elidable* argument was added.

## RunPython

**class RunPython** (*code*, *reverse\_code=None*, *atomic=None*, *hints=None*, *elidable=False*)

Runs custom Python code in a historical context. *code* (and *reverse\_code* if supplied) should be callable objects that accept two arguments; the first is an instance of `django.apps.registry.Apps` containing historical models that match the operation's place in the project history, and the second is an instance of `SchemaEditor`.

The *reverse\_code* argument is called when unapplying migrations. This callable should undo what is done in the *code* callable so that the migration is reversible.

The optional *hints* argument will be passed as `**hints` to the `allow_migrate()` method of database routers to assist them in making a routing decision. See [Hints](#) for more details on database hints.

The optional *elidable* argument determines whether or not the operation will be removed (elided) when [squashing migrations](#).

You are advised to write the code as a separate function above the `Migration` class in the migration file, and just pass it to `RunPython`. Here's an example of using `RunPython` to create some initial objects on a `Country` model:

```
# -*- coding: utf-8 -*-
from __future__ import unicode_literals

from django.db import migrations, models

def forwards_func(apps, schema_editor):
    # We get the model from the versioned app registry;
    # if we directly import it, it'll be the wrong version
    Country = apps.get_model("myapp", "Country")
    db_alias = schema_editor.connection.alias
    Country.objects.using(db_alias).bulk_create([
        Country(name="USA", code="us"),
        Country(name="France", code="fr"),
    ])

def reverse_func(apps, schema_editor):
    # forwards_func() creates two Country instances,
    # so reverse_func() should delete them.
    Country = apps.get_model("myapp", "Country")
    db_alias = schema_editor.connection.alias
    Country.objects.using(db_alias).filter(name="USA", code="us").delete()
    Country.objects.using(db_alias).filter(name="France", code="fr").delete()

class Migration(migrations.Migration):

    dependencies = []

    operations = [
        migrations.RunPython(forwards_func, reverse_func),
    ]
```

This is generally the operation you would use to create [data migrations](#), run custom data updates and alterations, and anything else you need access to an ORM and/or Python code for.

If you're upgrading from South, this is basically the South pattern as an operation - one or two methods for forwards and backwards, with an ORM and schema operations available. Most of the time, you should be able to translate the `orm.Model` or `orm["appname", "Model"]` references from South directly into `apps.get_model("appname", "Model")` references here and leave most of the rest of the code unchanged for data migrations. However, `apps` will only have references to models in the current app unless migrations in other apps are added to the migration's dependencies.

Much like `RunSQL`, ensure that if you change schema inside here you're either doing it outside the scope of the Django model system (e.g. triggers) or that you use `SeparateDatabaseAndState` to add in operations that will reflect your changes to the model state - otherwise, the versioned ORM and the autodetector will stop working correctly.

By default, `RunPython` will run its contents inside a transaction on databases that do not support DDL transactions (for example, MySQL and Oracle). This should be safe, but may cause a crash if you attempt to use the `schema_editor` provided on these backends; in this case, pass `atomic=False` to the `RunPython` operation.

On databases that do support DDL transactions (SQLite and PostgreSQL), `RunPython` operations do not have any transactions automatically added besides the transactions created for each migration. Thus, on PostgreSQL, for example, you should avoid combining schema changes and `RunPython` operations in the same migration or you may hit errors like `OperationalError: cannot ALTER TABLE "mytable" because it has pending trigger events`.

If you have a different database and aren't sure if it supports DDL transactions, check the `django.db.connection.features.can_rollback_ddl` attribute.

If the `RunPython` operation is part of a *non-atomic migration*, the operation will only be executed in a transaction if `atomic=True` is passed to the `RunPython` operation.

**Warning:** `RunPython` does not magically alter the connection of the models for you; any model methods you call will go to the default database unless you give them the current database alias (available from `schema_editor.connection.alias`, where `schema_editor` is the second argument to your function).

**static** `RunPython.noop()`

Pass the `RunPython.noop` method to `code` or `reverse_code` when you want the operation not to do anything in the given direction. This is especially useful in making the operation reversible.

The `elidable` argument was added.

The `atomic` argument default was changed to `None`, indicating that the atomicity is controlled by the `atomic` attribute of the migration.

### SeparateDatabaseAndState

**class** `SeparateDatabaseAndState` (*database\_operations=None, state\_operations=None*)

A highly specialized operation that let you mix and match the database (schema-changing) and state (autodetector-powering) aspects of operations.

It accepts two list of operations, and when asked to apply state will use the state list, and when asked to apply changes to the database will use the database list. Do not use this operation unless you're very sure you know what you're doing.

## 6.14.3 Writing your own

Operations have a relatively simple API, and they're designed so that you can easily write your own to supplement the built-in Django ones. The basic structure of an `Operation` looks like this:

```
from django.db.migrations.operations.base import Operation

class MyCustomOperation(Operation):

    # If this is False, it means that this operation will be ignored by
    # sqlmigrate; if true, it will be run and the SQL collected for its output.
    reduces_to_sql = False
```

```

# If this is False, Django will refuse to reverse past this operation.
reversible = False

def __init__(self, arg1, arg2):
    # Operations are usually instantiated with arguments in migration
    # files. Store the values of them on self for later use.
    pass

def state_forwards(self, app_label, state):
    # The Operation should take the 'state' parameter (an instance of
    # django.db.migrations.state.ProjectState) and mutate it to match
    # any schema changes that have occurred.
    pass

def database_forwards(self, app_label, schema_editor, from_state, to_state):
    # The Operation should use schema_editor to apply any changes it
    # wants to make to the database.
    pass

def database_backwards(self, app_label, schema_editor, from_state, to_state):
    # If reversible is True, this is called when the operation is reversed.
    pass

def describe(self):
    # This is used to describe what the operation does in console output.
    return "Custom Operation"

```

You can take this template and work from it, though we suggest looking at the built-in Django operations in `django.db.migrations.operations` - they're easy to read and cover a lot of the example usage of semi-internal aspects of the migration framework like `ProjectState` and the patterns used to get historical models, as well as `ModelState` and the patterns used to mutate historical models in `state_forwards()`.

Some things to note:

- You don't need to learn too much about `ProjectState` to just write simple migrations; just know that it has an `apps` property that gives access to an app registry (which you can then call `get_model` on).
- `database_forwards` and `database_backwards` both get two states passed to them; these just represent the difference the `state_forwards` method would have applied, but are given to you for convenience and speed reasons.
- `to_state` in the `database_backwards` method is the *older* state; that is, the one that will be the current state once the migration has finished reversing.
- You might see implementations of `references_model` on the built-in operations; this is part of the auto-detection code and does not matter for custom operations.

**Warning:** For performance reasons, the `Field` instances in `ModelState.fields` are reused across migrations. You must never change the attributes on these instances. If you need to mutate a field in `state_forwards()`, you must remove the old instance from `ModelState.fields` and add a new instance in its place. The same is true for the `Manager` instances in `ModelState.managers`.

As a simple example, let's make an operation that loads PostgreSQL extensions (which contain some of PostgreSQL's more exciting features). It's simple enough; there's no model state changes, and all it does is run one command:

```
from django.db.migrations.operations.base import Operation

class LoadExtension(Operation):

    reversible = True

    def __init__(self, name):
        self.name = name

    def state_forwards(self, app_label, state):
        pass

    def database_forwards(self, app_label, schema_editor, from_state, to_state):
        schema_editor.execute("CREATE EXTENSION IF NOT EXISTS %s" % self.name)

    def database_backwards(self, app_label, schema_editor, from_state, to_state):
        schema_editor.execute("DROP EXTENSION %s" % self.name)

    def describe(self):
        return "Creates extension %s" % self.name
```

## 6.15 Models

Model API reference. For introductory material, see *Models*.

### 6.15.1 Model field reference

This document contains all the API references of *Field* including the *field options* and *field types* Django offers.

See also:

If the built-in fields don't do the trick, you can try [django-localflavor \(documentation\)](#), which contains assorted pieces of code that are useful for particular countries and cultures.

Also, you can easily *write your own custom model fields*.

---

**Note:** Technically, these models are defined in *django.db.models.fields*, but for convenience they're imported into *django.db.models*; the standard convention is to use `from django.db import models` and refer to fields as `models.<Foo>Field`.

---

#### Field options

The following arguments are available to all field types. All are optional.

##### **null**

`Field.null`

If `True`, Django will store empty values as `NULL` in the database. Default is `False`.

Avoid using `null` on string-based fields such as `CharField` and `TextField` because empty string values will always be stored as empty strings, not as `NULL`. If a string-based field has `null=True`, that means it has two possible values for “no data”: `NULL`, and the empty string. In most cases, it’s redundant to have two possible values for “no data;” the Django convention is to use the empty string, not `NULL`.

For both string-based and non-string-based fields, you will also need to set `blank=True` if you wish to permit empty values in forms, as the `null` parameter only affects database storage (see `blank`).

---

**Note:** When using the Oracle database backend, the value `NULL` will be stored to denote the empty string regardless of this attribute.

---

If you want to accept `null` values with `BooleanField`, use `NullBooleanField` instead.

## blank

### Field.blank

If `True`, the field is allowed to be blank. Default is `False`.

Note that this is different than `null`. `null` is purely database-related, whereas `blank` is validation-related. If a field has `blank=True`, form validation will allow entry of an empty value. If a field has `blank=False`, the field will be required.

## choices

### Field.choices

An iterable (e.g., a list or tuple) consisting itself of iterables of exactly two items (e.g. `[(A, B), (A, B) ...]`) to use as choices for this field. If this is given, the default form widget will be a select box with these choices instead of the standard text field.

The first element in each tuple is the actual value to be set on the model, and the second element is the human-readable name. For example:

```
YEAR_IN_SCHOOL_CHOICES = (
    ('FR', 'Freshman'),
    ('SO', 'Sophomore'),
    ('JR', 'Junior'),
    ('SR', 'Senior'),
)
```

Generally, it’s best to define choices inside a model class, and to define a suitably-named constant for each value:

```
from django.db import models

class Student(models.Model):
    FRESHMAN = 'FR'
    SOPHOMORE = 'SO'
    JUNIOR = 'JR'
    SENIOR = 'SR'
    YEAR_IN_SCHOOL_CHOICES = (
        (FRESHMAN, 'Freshman'),
        (SOPHOMORE, 'Sophomore'),
        (JUNIOR, 'Junior'),
        (SENIOR, 'Senior'),
    )
```

```
)
year_in_school = models.CharField(
    max_length=2,
    choices=YEAR_IN_SCHOOL_CHOICES,
    default=FRESHMAN,
)

def is_upperclass(self):
    return self.year_in_school in (self.JUNIOR, self.SENIOR)
```

Though you can define a choices list outside of a model class and then refer to it, defining the choices and names for each choice inside the model class keeps all of that information with the class that uses it, and makes the choices easy to reference (e.g. `Student.SOPHOMORE` will work anywhere that the `Student` model has been imported).

You can also collect your available choices into named groups that can be used for organizational purposes:

```
MEDIA_CHOICES = (
    ('Audio', (
        ('vinyl', 'Vinyl'),
        ('cd', 'CD'),
    )),
    ('Video', (
        ('vhs', 'VHS Tape'),
        ('dvd', 'DVD'),
    )),
    ('unknown', 'Unknown'),
)
```

The first element in each tuple is the name to apply to the group. The second element is an iterable of 2-tuples, with each 2-tuple containing a value and a human-readable name for an option. Grouped options may be combined with ungrouped options within a single list (such as the *unknown* option in this example).

For each model field that has *choices* set, Django will add a method to retrieve the human-readable name for the field's current value. See *get\_FOO\_display()* in the database API documentation.

Note that choices can be any iterable object – not necessarily a list or tuple. This lets you construct choices dynamically. But if you find yourself hacking *choices* to be dynamic, you're probably better off using a proper database table with a *ForeignKey*. *choices* is meant for static data that doesn't change much, if ever.

Unless *blank=False* is set on the field along with a *default* then a label containing "-----" will be rendered with the select box. To override this behavior, add a tuple to *choices* containing *None*; e.g. `(None, 'Your String For Display')`. Alternatively, you can use an empty string instead of *None* where this makes sense – such as on a *CharField*.

## db\_column

### Field.db\_column

The name of the database column to use for this field. If this isn't given, Django will use the field's name.

If your database column name is an SQL reserved word, or contains characters that aren't allowed in Python variable names – notably, the hyphen – that's OK. Django quotes column and table names behind the scenes.

### `db_index`

#### Field.`db_index`

If `True`, a database index will be created for this field.

### `db_tablespace`

#### Field.`db_tablespace`

The name of the *database tablespace* to use for this field's index, if this field is indexed. The default is the project's `DEFAULT_INDEX_TABLESPACE` setting, if set, or the `db_tablespace` of the model, if any. If the backend doesn't support tablespaces for indexes, this option is ignored.

### `default`

#### Field.`default`

The default value for the field. This can be a value or a callable object. If callable it will be called every time a new object is created.

The default can't be a mutable object (model instance, `list`, `set`, etc.), as a reference to the same instance of that object would be used as the default value in all new model instances. Instead, wrap the desired default in a callable. For example, if you want to specify a default dict for `JSONField`, use a function:

```
def contact_default():
    return {"email": "tol@example.com"}

contact_info = JSONField("ContactInfo", default=contact_default)
```

lambdas can't be used for field options like `default` because they can't be *serialized by migrations*. See that documentation for other caveats.

For fields like `ForeignKey` that map to model instances, defaults should be the value of the field they reference (pk unless `to_field` is set) instead of model instances.

The default value is used when new model instances are created and a value isn't provided for the field. When the field is a primary key, the default is also used when the field is set to `None`.

### `editable`

#### Field.`editable`

If `False`, the field will not be displayed in the admin or any other `ModelForm`. They are also skipped during *model validation*. Default is `True`.

### `error_messages`

#### Field.`error_messages`

The `error_messages` argument lets you override the default messages that the field will raise. Pass in a dictionary with keys matching the error messages you want to override.

Error message keys include `null`, `blank`, `invalid`, `invalid_choice`, `unique`, and `unique_for_date`. Additional error message keys are specified for each field in the *Field types* section below.

## help\_text

### Field.help\_text

Extra “help” text to be displayed with the form widget. It’s useful for documentation even if your field isn’t used on a form.

Note that this value is *not* HTML-escaped in automatically-generated forms. This lets you include HTML in `help_text` if you so desire. For example:

```
help_text="Please use the following format: <em>YYYY-MM-DD</em>."
```

Alternatively you can use plain text and `django.utils.html.escape()` to escape any HTML special characters. Ensure that you escape any help text that may come from untrusted users to avoid a cross-site scripting attack.

## primary\_key

### Field.primary\_key

If `True`, this field is the primary key for the model.

If you don’t specify `primary_key=True` for any field in your model, Django will automatically add an *AutoField* to hold the primary key, so you don’t need to set `primary_key=True` on any of your fields unless you want to override the default primary-key behavior. For more, see *Automatic primary key fields*.

`primary_key=True` implies `null=False` and `unique=True`. Only one primary key is allowed on an object.

The primary key field is read-only. If you change the value of the primary key on an existing object and then save it, a new object will be created alongside the old one.

## unique

### Field.unique

If `True`, this field must be unique throughout the table.

This is enforced at the database level and by model validation. If you try to save a model with a duplicate value in a *unique* field, a *django.db.IntegrityError* will be raised by the model’s `save()` method.

This option is valid on all field types except *ManyToManyField*, *OneToOneField*, and *FileField*.

Note that when `unique` is `True`, you don’t need to specify `db_index`, because `unique` implies the creation of an index.

## unique\_for\_date

### Field.unique\_for\_date

Set this to the name of a *DateField* or *DateTimeField* to require that this field be unique for the value of the date field.

For example, if you have a field `title` that has `unique_for_date="pub_date"`, then Django wouldn’t allow the entry of two records with the same `title` and `pub_date`.

Note that if you set this to point to a *DateTimeField*, only the date portion of the field will be considered. Besides, when `USE_TZ` is `True`, the check will be performed in the *current time zone* at the time the object gets saved.

This is enforced by `Model.validate_unique()` during model validation but not at the database level. If any `unique_for_date` constraint involves fields that are not part of a `ModelForm` (for example, if one of the fields is listed in `exclude` or has `editable=False`), `Model.validate_unique()` will skip validation for that particular constraint.

### `unique_for_month`

`Field.unique_for_month`

Like `unique_for_date`, but requires the field to be unique with respect to the month.

### `unique_for_year`

`Field.unique_for_year`

Like `unique_for_date` and `unique_for_month`.

### `verbose_name`

`Field.verbose_name`

A human-readable name for the field. If the verbose name isn't given, Django will automatically create it using the field's attribute name, converting underscores to spaces. See [Verbose field names](#).

### `validators`

`Field.validators`

A list of validators to run for this field. See the [validators documentation](#) for more information.

## Registering and fetching lookups

Field implements the [lookup registration API](#). The API can be used to customize which lookups are available for a field class, and how lookups are fetched from a field.

## Field types

### `AutoField`

`class AutoField(**options)`

An `IntegerField` that automatically increments according to available IDs. You usually won't need to use this directly; a primary key field will automatically be added to your model if you don't specify otherwise. See [Automatic primary key fields](#).

### BigAutoField

```
class BigAutoField(**options)
```

A 64-bit integer, much like an *AutoField* except that it is guaranteed to fit numbers from 1 to 9223372036854775807.

### BigIntegerField

```
class BigIntegerField(**options)
```

A 64-bit integer, much like an *IntegerField* except that it is guaranteed to fit numbers from -9223372036854775808 to 9223372036854775807. The default form widget for this field is a *TextInput*.

### BinaryField

```
class BinaryField(**options)
```

A field to store raw binary data. It only supports `bytes` assignment. Be aware that this field has limited functionality. For example, it is not possible to filter a queryset on a *BinaryField* value. It is also not possible to include a *BinaryField* in a *ModelForm*.

---

### Abusing BinaryField

Although you might think about storing files in the database, consider that it is bad design in 99% of the cases. This field is *not* a replacement for proper *static files* handling.

---

### BooleanField

```
class BooleanField(**options)
```

A true/false field.

The default form widget for this field is a *CheckboxInput*.

If you need to accept *null* values then use *NullBooleanField* instead.

The default value of *BooleanField* is `None` when *Field.default* isn't defined.

### CharField

```
class CharField(max_length=None, **options)
```

A string field, for small- to large-sized strings.

For large amounts of text, use *TextField*.

The default form widget for this field is a *TextInput*.

*CharField* has one extra required argument:

**CharField.max\_length**

The maximum length (in characters) of the field. The `max_length` is enforced at the database level and in Django's validation.

**Note:** If you are writing an application that must be portable to multiple database backends, you should be aware that there are restrictions on `max_length` for some backends. Refer to the [database backend notes](#) for details.

---

## MySQL users

If you are using this field with MySQLdb 1.2.2 and the `utf8_bin` collation (which is *not* the default), there are some issues to be aware of. Refer to the [MySQL database notes](#) for details.

---

## CommaSeparatedIntegerField

```
class CommaSeparatedIntegerField(max_length=None, **options)
```

Deprecated since version 1.9: This field is deprecated in favor of `CharField` with `validators=[validate_comma_separated_integer_list]`.

A field of integers separated by commas. As in `CharField`, the `max_length` argument is required and the note about database portability mentioned there should be heeded.

## DateField

```
class DateField(auto_now=False, auto_now_add=False, **options)
```

A date, represented in Python by a `datetime.date` instance. Has a few extra, optional arguments:

### `DateField.auto_now`

Automatically set the field to now every time the object is saved. Useful for “last-modified” timestamps. Note that the current date is *always* used; it’s not just a default value that you can override.

The field is only automatically updated when calling `Model.save()`. The field isn’t updated when making updates to other fields in other ways such as `QuerySet.update()`, though you can specify a custom value for the field in an update like that.

### `DateField.auto_now_add`

Automatically set the field to now when the object is first created. Useful for creation of timestamps. Note that the current date is *always* used; it’s not just a default value that you can override. So even if you set a value for this field when creating the object, it will be ignored. If you want to be able to modify this field, set the following instead of `auto_now_add=True`:

- For `DateField`: `default=date.today` - from `datetime.date.today()`
- For `DateTimeField`: `default=timezone.now` - from `django.utils.timezone.now()`

The default form widget for this field is a `TextInput`. The admin adds a JavaScript calendar, and a shortcut for “Today”. Includes an additional `invalid_date` error message key.

The options `auto_now_add`, `auto_now`, and `default` are mutually exclusive. Any combination of these options will result in an error.

---

**Note:** As currently implemented, setting `auto_now` or `auto_now_add` to `True` will cause the field to have `editable=False` and `blank=True` set.

---

**Note:** The `auto_now` and `auto_now_add` options will always use the date in the *default timezone* at the moment of creation or update. If you need something different, you may want to consider simply using your own callable default or overriding `save()` instead of using `auto_now` or `auto_now_add`; or using a `DateTimeField` instead of a `DateTimeField` and deciding how to handle the conversion from datetime to date at display time.

---

### `DateTimeField`

**class** `DateTimeField` (*auto\_now=False, auto\_now\_add=False, \*\*options*)

A date and time, represented in Python by a `datetime.datetime` instance. Takes the same extra arguments as `DateField`.

The default form widget for this field is a single `TextInput`. The admin uses two separate `TextInput` widgets with JavaScript shortcuts.

### `DecimalField`

**class** `DecimalField` (*max\_digits=None, decimal\_places=None, \*\*options*)

A fixed-precision decimal number, represented in Python by a `Decimal` instance. Has two **required** arguments:

`DecimalField.max_digits`

The maximum number of digits allowed in the number. Note that this number must be greater than or equal to `decimal_places`.

`DecimalField.decimal_places`

The number of decimal places to store with the number.

For example, to store numbers up to 999 with a resolution of 2 decimal places, you'd use:

```
models.DecimalField(..., max_digits=5, decimal_places=2)
```

And to store numbers up to approximately one billion with a resolution of 10 decimal places:

```
models.DecimalField(..., max_digits=19, decimal_places=10)
```

The default form widget for this field is a `NumberInput` when `localize` is `False` or `TextInput` otherwise.

---

**Note:** For more information about the differences between the `FloatField` and `DecimalField` classes, please see *FloatField vs. DecimalField*.

---

### `DurationField`

**class** `DurationField` (*\*\*options*)

A field for storing periods of time - modeled in Python by `timedelta`. When used on PostgreSQL, the data type used is an `interval` and on Oracle the data type is `INTERVAL DAY(9) TO SECOND(6)`. Otherwise a bigint of microseconds is used.

---

**Note:** Arithmetic with `DurationField` works in most cases. However on all databases other than PostgreSQL, comparing the value of a `DurationField` to arithmetic on `DateTimeField` instances will not work as expected.

---

### EmailField

```
class EmailField(max_length=254, **options)
```

A `CharField` that checks that the value is a valid email address. It uses `EmailValidator` to validate the input.

### FileField

```
class FileField(upload_to=None, max_length=100, **options)
```

A file-upload field.

---

**Note:** The `primary_key` and `unique` arguments are not supported, and will raise a `TypeError` if used.

---

Has two optional arguments:

#### FileField.upload\_to

This attribute provides a way of setting the upload directory and file name, and can be set in two ways. In both cases, the value is passed to the `Storage.save()` method.

If you specify a string value, it may contain `strftime()` formatting, which will be replaced by the date/time of the file upload (so that uploaded files don't fill up the given directory). For example:

```
class MyModel(models.Model):
    # file will be uploaded to MEDIA_ROOT/uploads
    upload = models.FileField(upload_to='uploads/')
    # or...
    # file will be saved to MEDIA_ROOT/uploads/2015/01/30
    upload = models.FileField(upload_to='uploads/%Y/%m/%d/')
```

If you are using the default `FileSystemStorage`, the string value will be appended to your `MEDIA_ROOT` path to form the location on the local filesystem where uploaded files will be stored. If you are using a different storage, check that storage's documentation to see how it handles `upload_to`.

`upload_to` may also be a callable, such as a function. This will be called to obtain the upload path, including the filename. This callable must accept two arguments and return a Unix-style path (with forward slashes) to be passed along to the storage system. The two arguments are:

Argument	Description
instance	An instance of the model where the <code>FileField</code> is defined. More specifically, this is the particular instance where the current file is being attached. In most cases, this object will not have been saved to the database yet, so if it uses the default <code>AutoField</code> , it might not yet have a value for its <i>primary key field</i> .
filename	The filename that was originally given to the file. This may or may not be taken into account when determining the final destination path.

For example:

```
def user_directory_path(instance, filename):
    # file will be uploaded to MEDIA_ROOT/user_<id>/<filename>
    return 'user_{0}/{1}'.format(instance.user.id, filename)

class MyModel(models.Model):
    upload = models.FileField(upload_to=user_directory_path)
```

### FileField.storage

A storage object, which handles the storage and retrieval of your files. See *Managing files* for details on how to provide this object.

The default form widget for this field is a *ClearableFileInput*.

Using a *FileField* or an *ImageField* (see below) in a model takes a few steps:

1. In your settings file, you'll need to define *MEDIA\_ROOT* as the full path to a directory where you'd like Django to store uploaded files. (For performance, these files are not stored in the database.) Define *MEDIA\_URL* as the base public URL of that directory. Make sure that this directory is writable by the Web server's user account.
2. Add the *FileField* or *ImageField* to your model, defining the *upload\_to* option to specify a subdirectory of *MEDIA\_ROOT* to use for uploaded files.
3. All that will be stored in your database is a path to the file (relative to *MEDIA\_ROOT*). You'll most likely want to use the convenience *url* attribute provided by Django. For example, if your *ImageField* is called *mug\_shot*, you can get the absolute path to your image in a template with `{{ object.mug_shot.url }}`.

For example, say your *MEDIA\_ROOT* is set to  `'/home/media'`, and *upload\_to* is set to  `'photos/%Y/%m/%d'`. The  `'Y/%m/%d'` part of *upload\_to* is *strftime()* formatting;  `'Y'` is the four-digit year,  `'m'` is the two-digit month and  `'d'` is the two-digit day. If you upload a file on Jan. 15, 2007, it will be saved in the directory  `/home/media/photos/2007/01/15`.

If you wanted to retrieve the uploaded file's on-disk filename, or the file's size, you could use the *name* and *size* attributes respectively; for more information on the available attributes and methods, see the *File* class reference and the *Managing files* topic guide.

---

**Note:** The file is saved as part of saving the model in the database, so the actual file name used on disk cannot be relied on until after the model has been saved.

---

The uploaded file's relative URL can be obtained using the *url* attribute. Internally, this calls the *url()* method of the underlying *Storage* class. Note that whenever you deal with uploaded files, you should pay close attention to where you're uploading them and what type of files they are, to avoid security holes. *Validate all uploaded files* so that you're sure the files are what you think they are. For example, if you blindly let somebody upload files, without validation, to a directory that's within your Web server's document root, then somebody could upload a CGI or PHP script and execute that script by visiting its URL on your site. Don't allow that.

Also note that even an uploaded HTML file, since it can be executed by the browser (though not by the server), can pose security threats that are equivalent to XSS or CSRF attacks.

*FileField* instances are created in your database as  `varchar` columns with a default max length of 100 characters. As with other fields, you can change the maximum length using the *max\_length* argument.

## FileField and FieldFile

### class FieldFile

When you access a `FileField` on a model, you are given an instance of `FieldFile` as a proxy for accessing the underlying file.

The API of `FieldFile` mirrors that of `File`, with one key difference: *The object wrapped by the class is not necessarily a wrapper around Python's built-in file object.* Instead, it is a wrapper around the result of the `Storage.open()` method, which may be a `File` object, or it may be a custom storage's implementation of the `File` API.

In addition to the API inherited from `File` such as `read()` and `write()`, `FieldFile` includes several methods that can be used to interact with the underlying file:

**Warning:** Two methods of this class, `save()` and `delete()`, default to saving the model object of the associated `FieldFile` in the database.

`FieldFile.name`

The name of the file including the relative path from the root of the `Storage` of the associated `FileField`.

`FieldFile.size`

The result of the underlying `Storage.size()` method.

`FieldFile.url`

A read-only property to access the file's relative URL by calling the `url()` method of the underlying `Storage` class.

`FieldFile.open(mode='rb')`

Opens or reopens the file associated with this instance in the specified mode. Unlike the standard Python `open()` method, it doesn't return a file descriptor.

Since the underlying file is opened implicitly when accessing it, it may be unnecessary to call this method except to reset the pointer to the underlying file or to change the mode.

`FieldFile.close()`

Behaves like the standard Python `file.close()` method and closes the file associated with this instance.

`FieldFile.save(name, content, save=True)`

This method takes a filename and file contents and passes them to the storage class for the field, then associates the stored file with the model field. If you want to manually associate file data with `FileField` instances on your model, the `save()` method is used to persist that file data.

Takes two required arguments: `name` which is the name of the file, and `content` which is an object containing the file's contents. The optional `save` argument controls whether or not the model instance is saved after the file associated with this field has been altered. Defaults to `True`.

Note that the `content` argument should be an instance of `django.core.files.File`, not Python's built-in file object. You can construct a `File` from an existing Python file object like this:

```
from django.core.files import File
# Open an existing file using Python's built-in open()
f = open('/path/to/hello.world')
myfile = File(f)
```

Or you can construct one from a Python string like this:

```
from django.core.files.base import ContentFile
myfile = ContentFile("hello world")
```

For more information, see [Managing files](#).

`FieldFile.delete` (*save=True*)

Deletes the file associated with this instance and clears all attributes on the field. Note: This method will close the file if it happens to be open when `delete()` is called.

The optional `save` argument controls whether or not the model instance is saved after the file associated with this field has been deleted. Defaults to `True`.

Note that when a model is deleted, related files are not deleted. If you need to cleanup orphaned files, you'll need to handle it yourself (for instance, with a custom management command that can be run manually or scheduled to run periodically via e.g. cron).

## FilePathField

**class** `FilePathField` (*path=None, match=None, recursive=False, max\_length=100, \*\*options*)

A `CharField` whose choices are limited to the filenames in a certain directory on the filesystem. Has three special arguments, of which the first is **required**:

`FilePathField.path`

Required. The absolute filesystem path to a directory from which this `FilePathField` should get its choices. Example: `"/home/images"`.

`FilePathField.match`

Optional. A regular expression, as a string, that `FilePathField` will use to filter filenames. Note that the regex will be applied to the base filename, not the full path. Example: `"foo.*\.txt$"`, which will match a file called `foo23.txt` but not `bar.txt` or `foo23.png`.

`FilePathField.recursive`

Optional. Either `True` or `False`. Default is `False`. Specifies whether all subdirectories of `path` should be included

`FilePathField.allow_files`

Optional. Either `True` or `False`. Default is `True`. Specifies whether files in the specified location should be included. Either this or `allow_folders` must be `True`.

`FilePathField.allow_folders`

Optional. Either `True` or `False`. Default is `False`. Specifies whether folders in the specified location should be included. Either this or `allow_files` must be `True`.

Of course, these arguments can be used together.

The one potential gotcha is that `match` applies to the base filename, not the full path. So, this example:

```
FilePathField(path="/home/images", match="foo.*", recursive=True)
```

...will match `/home/images/foo.png` but not `/home/images/foo/bar.png` because the `match` applies to the base filename (`foo.png` and `bar.png`).

`FilePathField` instances are created in your database as `varchar` columns with a default max length of 100 characters. As with other fields, you can change the maximum length using the `max_length` argument.

## FloatField

**class** `FloatField` (*\*\*options*)

A floating-point number represented in Python by a `float` instance.

The default form widget for this field is a `NumberInput` when `localize` is `False` or `TextInput` otherwise.

### FloatField vs. DecimalField

The `FloatField` class is sometimes mixed up with the `DecimalField` class. Although they both represent real numbers, they represent those numbers differently. `FloatField` uses Python's `float` type internally, while `DecimalField` uses Python's `Decimal` type. For information on the difference between the two, see Python's documentation for the `decimal` module.

---

### ImageField

```
class ImageField(upload_to=None, height_field=None, width_field=None, max_length=100, **options)
```

Inherits all attributes and methods from `FileField`, but also validates that the uploaded object is a valid image.

In addition to the special attributes that are available for `FileField`, an `ImageField` also has `height` and `width` attributes.

To facilitate querying on those attributes, `ImageField` has two extra optional arguments:

`ImageField.height_field`

Name of a model field which will be auto-populated with the height of the image each time the model instance is saved.

`ImageField.width_field`

Name of a model field which will be auto-populated with the width of the image each time the model instance is saved.

Requires the `Pillow` library.

`ImageField` instances are created in your database as `varchar` columns with a default max length of 100 characters. As with other fields, you can change the maximum length using the `max_length` argument.

The default form widget for this field is a `ClearableFileInput`.

### IntegerField

```
class IntegerField(**options)
```

An integer. Values from `-2147483648` to `2147483647` are safe in all databases supported by Django. The default form widget for this field is a `NumberInput` when `localize` is `False` or `TextInput` otherwise.

### GenericIPAddressField

```
class GenericIPAddressField(protocol='both', unpack_ipv4=False, **options)
```

An IPv4 or IPv6 address, in string format (e.g. `192.0.2.30` or `2a02:42fe::4`). The default form widget for this field is a `TextInput`.

The IPv6 address normalization follows [RFC 4291#section-2.2](#) section 2.2, including using the IPv4 format suggested in paragraph 3 of that section, like `::ffff:192.0.2.0`. For example, `2001:0::0:01` would be normalized to `2001::1`, and `::ffff:0a0a:0a0a::` to `::ffff:10.10.10.10`. All characters are converted to lowercase.

`GenericIPAddressField.protocol`

Limits valid inputs to the specified protocol. Accepted values are `'both'` (default), `'IPv4'` or `'IPv6'`. Matching is case insensitive.

#### GenericIPAddressField.unpack\_ipv4

Unpacks IPv4 mapped addresses like `::ffff:192.0.2.1`. If this option is enabled that address would be unpacked to `192.0.2.1`. Default is disabled. Can only be used when `protocol` is set to `'both'`.

If you allow for blank values, you have to allow for null values since blank values are stored as null.

#### NullBooleanField

```
class NullBooleanField(**options)
```

Like a `BooleanField`, but allows NULL as one of the options. Use this instead of a `BooleanField` with `null=True`. The default form widget for this field is a `NullBooleanSelect`.

#### PositiveIntegerField

```
class PositiveIntegerField(**options)
```

Like an `IntegerField`, but must be either positive or zero (0). Values from 0 to 2147483647 are safe in all databases supported by Django. The value 0 is accepted for backward compatibility reasons.

#### PositiveSmallIntegerField

```
class PositiveSmallIntegerField(**options)
```

Like a `PositiveIntegerField`, but only allows values under a certain (database-dependent) point. Values from 0 to 32767 are safe in all databases supported by Django.

#### SlugField

```
class SlugField(max_length=50, **options)
```

*Slug* is a newspaper term. A slug is a short label for something, containing only letters, numbers, underscores or hyphens. They're generally used in URLs.

Like a `CharField`, you can specify `max_length` (read the note about database portability and `max_length` in that section, too). If `max_length` is not specified, Django will use a default length of 50.

Implies setting `Field.db_index` to `True`.

It is often useful to automatically prepopulate a `SlugField` based on the value of some other value. You can do this automatically in the admin using `prepopulated_fields`.

`SlugField.allow_unicode`

If `True`, the field accepts Unicode letters in addition to ASCII letters. Defaults to `False`.

#### SmallIntegerField

```
class SmallIntegerField(**options)
```

Like an `IntegerField`, but only allows values under a certain (database-dependent) point. Values from -32768 to 32767 are safe in all databases supported by Django.

## TextField

```
class TextField(**options)
```

A large text field. The default form widget for this field is a *Textarea*.

If you specify a `max_length` attribute, it will be reflected in the *Textarea* widget of the auto-generated form field. However it is not enforced at the model or database level. Use a *CharField* for that.

---

## MySQL users

If you are using this field with MySQLdb 1.2.1p2 and the `utf8_bin` collation (which is *not* the default), there are some issues to be aware of. Refer to the *MySQL database notes* for details.

---

## TimeField

```
class TimeField(auto_now=False, auto_now_add=False, **options)
```

A time, represented in Python by a `datetime.time` instance. Accepts the same auto-population options as *DateField*.

The default form widget for this field is a *TextInput*. The admin adds some JavaScript shortcuts.

## URLField

```
class URLField(max_length=200, **options)
```

A *CharField* for a URL.

The default form widget for this field is a *TextInput*.

Like all *CharField* subclasses, *URLField* takes the optional `max_length` argument. If you don't specify `max_length`, a default of 200 is used.

## UUIDField

```
class UUIDField(**options)
```

A field for storing universally unique identifiers. Uses Python's `UUID` class. When used on PostgreSQL, this stores in a `uuid` datatype, otherwise in a `char(32)`.

Universally unique identifiers are a good alternative to *AutoField* for *primary\_key*. The database will not generate the UUID for you, so it is recommended to use *default*:

```
import uuid
from django.db import models

class MyUUIDModel(models.Model):
    id = models.UUIDField(primary_key=True, default=uuid.uuid4, editable=False)
    # other fields
```

Note that a callable (with the parentheses omitted) is passed to `default`, not an instance of `UUID`.

## Relationship fields

Django also defines a set of fields that represent relations.

### ForeignKey

**class ForeignKey** (*othermodel*, *on\_delete*, *\*\*options*)

A many-to-one relationship. Requires a positional argument: the class to which the model is related.

`on_delete` can now be used as the second positional argument (previously it was typically only passed as a keyword argument). It will be a required argument in Django 2.0. To create a recursive relationship – an object that has a many-to-one relationship with itself – use `models.ForeignKey('self', on_delete=models.CASCADE)`. If you need to create a relationship on a model that has not yet been defined, you can use the name of the model, rather than the model object itself:

```
from django.db import models

class Car(models.Model):
    manufacturer = models.ForeignKey(
        'Manufacturer',
        on_delete=models.CASCADE,
    )
    # ...

class Manufacturer(models.Model):
    # ...
    pass
```

Relationships defined this way on *abstract models* are resolved when the model is subclassed as a concrete model and are not relative to the abstract model's `app_label`:

```
products/models.py

from django.db import models

class AbstractCar(models.Model):
    manufacturer = models.ForeignKey('Manufacturer', on_delete=models.CASCADE)

    class Meta:
        abstract = True
```

```
production/models.py

from django.db import models
from products.models import AbstractCar

class Manufacturer(models.Model):
    pass

class Car(AbstractCar):
    pass
```

```
# Car.manufacturer will point to `production.Manufacturer` here.
```

To refer to models defined in another application, you can explicitly specify a model with the full application label. For example, if the `Manufacturer` model above is defined in another application called `production`, you'd need to use:

```
class Car(models.Model):
    manufacturer = models.ForeignKey(
        'production.Manufacturer',
        on_delete=models.CASCADE,
    )
```

This sort of reference can be useful when resolving circular import dependencies between two applications.

A database index is automatically created on the `ForeignKey`. You can disable this by setting `db_index` to `False`. You may want to avoid the overhead of an index if you are creating a foreign key for consistency rather than joins, or if you will be creating an alternative index like a partial or multiple column index.

## Database Representation

Behind the scenes, Django appends `"_id"` to the field name to create its database column name. In the above example, the database table for the `Car` model will have a `manufacturer_id` column. (You can change this explicitly by specifying `db_column`) However, your code should never have to deal with the database column name, unless you write custom SQL. You'll always deal with the field names of your model object.

## Arguments

`ForeignKey` accepts other arguments that define the details of how the relation works.

### `ForeignKey.on_delete`

When an object referenced by a `ForeignKey` is deleted, Django will emulate the behavior of the SQL constraint specified by the `on_delete` argument. For example, if you have a nullable `ForeignKey` and you want it to be set null when the referenced object is deleted:

```
user = models.ForeignKey(
    User,
    models.SET_NULL,
    blank=True,
    null=True,
)
```

Deprecated since version 1.9: `on_delete` will become a required argument in Django 2.0. In older versions it defaults to `CASCADE`.

The possible values for `on_delete` are found in `django.db.models`:

- **CASCADE**  
Cascade deletes. Django emulates the behavior of the SQL constraint `ON DELETE CASCADE` and also deletes the object containing the `ForeignKey`.
- **PROTECT**  
Prevent deletion of the referenced object by raising `ProtectedError`, a subclass of `django.db.IntegrityError`.
- **SET\_NULL**  
Set the `ForeignKey` null; this is only possible if `null` is `True`.
- **SET\_DEFAULT**  
Set the `ForeignKey` to its default value; a default for the `ForeignKey` must be set.
- **SET()**  
Set the `ForeignKey` to the value passed to `SET()`, or if a callable is passed in, the result of calling it.

In most cases, passing a callable will be necessary to avoid executing queries at the time your models.py is imported:

```
from django.conf import settings
from django.contrib.auth import get_user_model
from django.db import models

def get_sentinel_user():
    return get_user_model().objects.get_or_create(username='deleted')[0]

class MyModel(models.Model):
    user = models.ForeignKey(
        settings.AUTH_USER_MODEL,
        on_delete=models.SET(get_sentinel_user),
    )
```

- **DO\_NOTHING**

Take no action. If your database backend enforces referential integrity, this will cause an *IntegrityError* unless you manually add an SQL ON DELETE constraint to the database field.

#### ForeignKey.limit\_choices\_to

Sets a limit to the available choices for this field when this field is rendered using a `ModelForm` or the admin (by default, all objects in the queryset are available to choose). Either a dictionary, a `Q` object, or a callable returning a dictionary or `Q` object can be used.

For example:

```
staff_member = models.ForeignKey(
    User,
    on_delete=models.CASCADE,
    limit_choices_to={'is_staff': True},
)
```

causes the corresponding field on the `ModelForm` to list only `Users` that have `is_staff=True`. This may be helpful in the Django admin.

The callable form can be helpful, for instance, when used in conjunction with the Python `datetime` module to limit selections by date range. For example:

```
def limit_pub_date_choices():
    return {'pub_date__lte': datetime.date.utcnow()}

limit_choices_to = limit_pub_date_choices
```

If `limit_choices_to` is or returns a `Q` object, which is useful for *complex queries*, then it will only have an effect on the choices available in the admin when the field is not listed in `raw_id_fields` in the `ModelAdmin` for the model.

---

**Note:** If a callable is used for `limit_choices_to`, it will be invoked every time a new form is instantiated. It may also be invoked when a model is validated, for example by management commands or the admin. The admin constructs querysets to validate its form inputs in various edge cases multiple times, so there is a possibility your callable may be invoked several times.

---

#### ForeignKey.related\_name

The name to use for the relation from the related object back to this one. It's also the default value for `related_query_name` (the name to use for the reverse filter name from the target model). See the *re-*

*lated objects documentation* for a full explanation and example. Note that you must set this value when defining relations on *abstract models*; and when you do so *some special syntax* is available.

If you'd prefer Django not to create a backwards relation, set `related_name` to '+' or end it with '+'. For example, this will ensure that the `User` model won't have a backwards relation to this model:

```
user = models.ForeignKey(
    User,
    on_delete=models.CASCADE,
    related_name='+',
)
```

#### `ForeignKey.related_query_name`

The name to use for the reverse filter name from the target model. It defaults to the value of `related_name` or `default_related_name` if set, otherwise it defaults to the name of the model:

```
# Declare the ForeignKey with related_query_name
class Tag(models.Model):
    article = models.ForeignKey(
        Article,
        on_delete=models.CASCADE,
        related_name="tags",
        related_query_name="tag",
    )
    name = models.CharField(max_length=255)

# That's now the name of the reverse filter
Article.objects.filter(tag__name="important")
```

Like `related_name`, `related_query_name` supports app label and class interpolation via *some special syntax*.

#### `ForeignKey.to_field`

The field on the related object that the relation is to. By default, Django uses the primary key of the related object. If you reference a different field, that field must have `unique=True`.

#### `ForeignKey.db_constraint`

Controls whether or not a constraint should be created in the database for this foreign key. The default is `True`, and that's almost certainly what you want; setting this to `False` can be very bad for data integrity. That said, here are some scenarios where you might want to do this:

- You have legacy data that is not valid.
- You're sharding your database.

If this is set to `False`, accessing a related object that doesn't exist will raise its `DoesNotExist` exception.

#### `ForeignKey.swappable`

Controls the migration framework's reaction if this `ForeignKey` is pointing at a swappable model. If it is `True` - the default - then if the `ForeignKey` is pointing at a model which matches the current value of `settings.AUTH_USER_MODEL` (or another swappable model setting) the relationship will be stored in the migration using a reference to the setting, not to the model directly.

You only want to override this to be `False` if you are sure your model should always point towards the swapped-in model - for example, if it is a profile model designed specifically for your custom user model.

Setting it to `False` does not mean you can reference a swappable model even if it is swapped out - `False` just means that the migrations made with this `ForeignKey` will always reference the exact model you specify (so it will fail hard if the user tries to run with a `User` model you don't support, for example).

If in doubt, leave it to its default of `True`.

## ManyToManyField

**class ManyToManyField** (*othermodel*, *\*\*options*)

A many-to-many relationship. Requires a positional argument: the class to which the model is related, which works exactly the same as it does for *ForeignKey*, including *recursive* and *lazy* relationships.

Related objects can be added, removed, or created with the field's *RelatedManager*.

## Database Representation

Behind the scenes, Django creates an intermediary join table to represent the many-to-many relationship. By default, this table name is generated using the name of the many-to-many field and the name of the table for the model that contains it. Since some databases don't support table names above a certain length, these table names will be automatically truncated to 64 characters and a uniqueness hash will be used. This means you might see table names like `author_books_9cdf4`; this is perfectly normal. You can manually provide the name of the join table using the *db\_table* option.

## Arguments

*ManyToManyField* accepts an extra set of arguments – all optional – that control how the relationship functions.

**ManyToManyField.related\_name**

Same as *ForeignKey.related\_name*.

**ManyToManyField.related\_query\_name**

Same as *ForeignKey.related\_query\_name*.

**ManyToManyField.limit\_choices\_to**

Same as *ForeignKey.limit\_choices\_to*.

*limit\_choices\_to* has no effect when used on a *ManyToManyField* with a custom intermediate table specified using the *through* parameter.

**ManyToManyField.symmetrical**

Only used in the definition of *ManyToManyFields* on self. Consider the following model:

```
from django.db import models

class Person(models.Model):
    friends = models.ManyToManyField("self")
```

When Django processes this model, it identifies that it has a *ManyToManyField* on itself, and as a result, it doesn't add a `person_set` attribute to the *Person* class. Instead, the *ManyToManyField* is assumed to be symmetrical – that is, if I am your friend, then you are my friend.

If you do not want symmetry in many-to-many relationships with *self*, set *symmetrical* to `False`. This will force Django to add the descriptor for the reverse relationship, allowing *ManyToManyField* relationships to be non-symmetrical.

**ManyToManyField.through**

Django will automatically generate a table to manage many-to-many relationships. However, if you want to manually specify the intermediary table, you can use the *through* option to specify the Django model that represents the intermediate table that you want to use.

The most common use for this option is when you want to associate *extra data with a many-to-many relationship*.

If you don't specify an explicit `through` model, there is still an implicit `through` model class you can use to directly access the table created to hold the association. It has three fields to link the models.

If the source and target models differ, the following fields are generated:

- `id`: the primary key of the relation.
- `<containing_model>_id`: the id of the model that declares the `ManyToManyField`.
- `<other_model>_id`: the id of the model that the `ManyToManyField` points to.

If the `ManyToManyField` points from and to the same model, the following fields are generated:

- `id`: the primary key of the relation.
- `from_<model>_id`: the id of the instance which points at the model (i.e. the source instance).
- `to_<model>_id`: the id of the instance to which the relationship points (i.e. the target model instance).

This class can be used to query associated records for a given model instance like a normal model.

#### `ManyToManyField.through_fields`

Only used when a custom intermediary model is specified. Django will normally determine which fields of the intermediary model to use in order to establish a many-to-many relationship automatically. However, consider the following models:

```
from django.db import models

class Person(models.Model):
    name = models.CharField(max_length=50)

class Group(models.Model):
    name = models.CharField(max_length=128)
    members = models.ManyToManyField(
        Person,
        through='Membership',
        through_fields=('group', 'person'),
    )

class Membership(models.Model):
    group = models.ForeignKey(Group, on_delete=models.CASCADE)
    person = models.ForeignKey(Person, on_delete=models.CASCADE)
    inviter = models.ForeignKey(
        Person,
        on_delete=models.CASCADE,
        related_name="membership_invites",
    )
    invite_reason = models.CharField(max_length=64)
```

`Membership` has *two* foreign keys to `Person` (`person` and `inviter`), which makes the relationship ambiguous and Django can't know which one to use. In this case, you must explicitly specify which foreign keys Django should use using `through_fields`, as in the example above.

`through_fields` accepts a 2-tuple ('field1', 'field2'), where `field1` is the name of the foreign key to the model the `ManyToManyField` is defined on (`group` in this case), and `field2` the name of the foreign key to the target model (`person` in this case).

When you have more than one foreign key on an intermediary model to any (or even both) of the models participating in a many-to-many relationship, you *must* specify `through_fields`. This also applies to *recursive relationships* when an intermediary model is used and there are more than two foreign keys to the model, or you want to explicitly specify which two Django should use.

Recursive relationships using an intermediary model are always defined as non-symmetrical – that is, with `symmetrical=False` – therefore, there is the concept of a “source” and a “target”. In that case `'field1'` will be treated as the “source” of the relationship and `'field2'` as the “target”.

#### `ManyToManyField.db_table`

The name of the table to create for storing the many-to-many data. If this is not provided, Django will assume a default name based upon the names of: the table for the model defining the relationship and the name of the field itself.

#### `ManyToManyField.db_constraint`

Controls whether or not constraints should be created in the database for the foreign keys in the intermediary table. The default is `True`, and that’s almost certainly what you want; setting this to `False` can be very bad for data integrity. That said, here are some scenarios where you might want to do this:

- You have legacy data that is not valid.
- You’re sharding your database.

It is an error to pass both `db_constraint` and `through`.

#### `ManyToManyField.swappable`

Controls the migration framework’s reaction if this `ManyToManyField` is pointing at a swappable model. If it is `True` - the default - then if the `ManyToManyField` is pointing at a model which matches the current value of `settings.AUTH_USER_MODEL` (or another swappable model setting) the relationship will be stored in the migration using a reference to the setting, not to the model directly.

You only want to override this to be `False` if you are sure your model should always point towards the swapped-in model - for example, if it is a profile model designed specifically for your custom user model.

If in doubt, leave it to its default of `True`.

`ManyToManyField` does not support `validators`.

`null` has no effect since there is no way to require a relationship at the database level.

## OneToOneField

```
class OneToOneField(othermodel, on_delete, parent_link=False, **options)
```

A one-to-one relationship. Conceptually, this is similar to a `ForeignKey` with `unique=True`, but the “reverse” side of the relation will directly return a single object.

`on_delete` can now be used as the second positional argument (previously it was typically only passed as a keyword argument). It will be a required argument in Django 2.0.

This is most useful as the primary key of a model which “extends” another model in some way; *Multi-table inheritance* is implemented by adding an implicit one-to-one relation from the child model to the parent model, for example.

One positional argument is required: the class to which the model will be related. This works exactly the same as it does for `ForeignKey`, including all the options regarding *recursive* and *lazy* relationships.

If you do not specify the `related_name` argument for the `OneToOneField`, Django will use the lower-case name of the current model as default value.

With the following example:

```
from django.conf import settings
from django.db import models

class MySpecialUser(models.Model):
    user = models.OneToOneField(
```

```

        settings.AUTH_USER_MODEL,
        on_delete=models.CASCADE,
    )
    supervisor = models.OneToOneField(
        settings.AUTH_USER_MODEL,
        on_delete=models.CASCADE,
        related_name='supervisor_of',
    )

```

your resulting `User` model will have the following attributes:

```

>>> user = User.objects.get(pk=1)
>>> hasattr(user, 'myspecialuser')
True
>>> hasattr(user, 'supervisor_of')
True

```

A `DoesNotExist` exception is raised when accessing the reverse relationship if an entry in the related table doesn't exist. For example, if a user doesn't have a supervisor designated by `MySpecialUser`:

```

>>> user.supervisor_of
Traceback (most recent call last):
...
DoesNotExist: User matching query does not exist.

```

Additionally, `OneToOneField` accepts all of the extra arguments accepted by `ForeignKey`, plus one extra argument:

#### `OneToOneField.parent_link`

When `True` and used in a model which inherits from another *concrete model*, indicates that this field should be used as the link back to the parent class, rather than the extra `OneToOneField` which would normally be implicitly created by subclassing.

See *One-to-one relationships* for usage examples of `OneToOneField`.

## Field API reference

### class `Field`

`Field` is an abstract class that represents a database table column. Django uses fields to create the database table (`db_type()`), to map Python types to database (`get_prep_value()`) and vice-versa (`from_db_value()`).

A field is thus a fundamental piece in different Django APIs, notably, *models* and *querysets*.

In models, a field is instantiated as a class attribute and represents a particular table column, see *Models*. It has attributes such as *null* and *unique*, and methods that Django uses to map the field value to database-specific values.

A `Field` is a subclass of `RegisterLookupMixin` and thus both `Transform` and `Lookup` can be registered on it to be used in `QuerySets` (e.g. `field_name__exact="foo"`). All *built-in lookups* are registered by default.

All of Django's built-in fields, such as `CharField`, are particular implementations of `Field`. If you need a custom field, you can either subclass any of the built-in fields or write a `Field` from scratch. In either case, see *Writing custom model fields*.

#### description

A verbose description of the field, e.g. for the `django.contrib.admindocs` application.

The description can be of the form:

```
description = _("String (up to %(max_length)s)")
```

where the arguments are interpolated from the field's `__dict__`.

To map a `Field` to a database-specific type, Django exposes several methods:

**get\_internal\_type()**

Returns a string naming this field for backend specific purposes. By default, it returns the class name.

See *Emulating built-in field types* for usage in custom fields.

**db\_type(connection)**

Returns the database column data type for the *Field*, taking into account the `connection`.

See *Custom database types* for usage in custom fields.

**rel\_db\_type(connection)**

Returns the database column data type for fields such as `ForeignKey` and `OneToOneField` that point to the *Field*, taking into account the `connection`.

See *Custom database types* for usage in custom fields.

There are three main situations where Django needs to interact with the database backend and fields:

- when it queries the database (Python value -> database backend value)
- when it loads data from the database (database backend value -> Python value)
- when it saves to the database (Python value -> database backend value)

When querying, `get_db_prep_value()` and `get_prep_value()` are used:

**get\_prep\_value(value)**

`value` is the current value of the model's attribute, and the method should return data in a format that has been prepared for use as a parameter in a query.

See *Converting Python objects to query values* for usage.

**get\_db\_prep\_value(value, connection, prepared=False)**

Converts `value` to a backend-specific value. By default it returns `value` if `prepared=True` and `get_prep_value()` if is `False`.

See *Converting query values to database values* for usage.

When loading data, `from_db_value()` is used:

**from\_db\_value(value, expression, connection, context)**

Converts a value as returned by the database to a Python object. It is the reverse of `get_prep_value()`.

This method is not used for most built-in fields as the database backend already returns the correct Python type, or the backend itself does the conversion.

See *Converting values to Python objects* for usage.

---

**Note:** For performance reasons, `from_db_value` is not implemented as a no-op on fields which do not require it (all Django fields). Consequently you may not call `super` in your definition.

---

When saving, `pre_save()` and `get_db_prep_save()` are used:

**get\_db\_prep\_save(value, connection)**

Same as the `get_db_prep_value()`, but called when the field value must be *saved* to the database. By default returns `get_db_prep_value()`.

**pre\_save** (*model\_instance*, *add*)

Method called prior to `get_db_prep_save()` to prepare the value before being saved (e.g. for `DateField.auto_now`).

`model_instance` is the instance this field belongs to and `add` is whether the instance is being saved to the database for the first time.

It should return the value of the appropriate attribute from `model_instance` for this field. The attribute name is in `self.attname` (this is set up by `Field`).

See *Preprocessing values before saving* for usage.

Fields often receive their values as a different type, either from serialization or from forms.

**to\_python** (*value*)

Converts the value into the correct Python object. It acts as the reverse of `value_to_string()`, and is also called in `clean()`.

See *Converting values to Python objects* for usage.

Besides saving to the database, the field also needs to know how to serialize its value:

**value\_to\_string** (*obj*)

Converts `obj` to a string. Used to serialize the value of the field.

See *Converting field data for serialization* for usage.

When using *model forms*, the `Field` needs to know which form field it should be represented by:

**formfield** (*form\_class=None*, *choices\_form\_class=None*, *\*\*kwargs*)

Returns the default `django.forms.Field` of this field for `ModelForm`.

By default, if both `form_class` and `choices_form_class` are `None`, it uses `CharField`. If the field has `choices` and `choices_form_class` isn't specified, it uses `TypedChoiceField`.

See *Specifying the form field for a model field* for usage.

**deconstruct** ()

Returns a 4-tuple with enough information to recreate the field:

1. The name of the field on the model.
2. The import path of the field (e.g. `"django.db.models.IntegerField"`). This should be the most portable version, so less specific may be better.
3. A list of positional arguments.
4. A dict of keyword arguments.

This method must be added to fields prior to 1.7 to migrate its data using *Migrations*.

## 6.15.2 Field attribute reference

Every `Field` instance contains several attributes that allow introspecting its behavior. Use these attributes instead of `isinstance` checks when you need to write code that depends on a field's functionality. These attributes can be used together with the *Model.\_meta API* to narrow down a search for specific field types. Custom model fields should implement these flags.

## Attributes for fields

### Field.`auto_created`

Boolean flag that indicates if the field was automatically created, such as the `OneToOneField` used by model inheritance.

### Field.`concrete`

Boolean flag that indicates if the field has a database column associated with it.

### Field.`hidden`

Boolean flag that indicates if a field is used to back another non-hidden field's functionality (e.g. the `content_type` and `object_id` fields that make up a `GenericForeignKey`). The `hidden` flag is used to distinguish what constitutes the public subset of fields on the model from all the fields on the model.

---

**Note:** `Options.get_fields()` excludes hidden fields by default. Pass in `include_hidden=True` to return hidden fields in the results.

---

### Field.`is_relation`

Boolean flag that indicates if a field contains references to one or more other models for its functionality (e.g. `ForeignKey`, `ManyToManyField`, `OneToOneField`, etc.).

### Field.`model`

Returns the model on which the field is defined. If a field is defined on a superclass of a model, `model` will refer to the superclass, not the class of the instance.

## Attributes for fields with relations

These attributes are used to query for the cardinality and other details of a relation. These attribute are present on all fields; however, they will only have boolean values (rather than `None`) if the field is a relation type (`Field.is_relation=True`).

### Field.`many_to_many`

Boolean flag that is `True` if the field has a many-to-many relation; `False` otherwise. The only field included with Django where this is `True` is `ManyToManyField`.

### Field.`many_to_one`

Boolean flag that is `True` if the field has a many-to-one relation, such as a `ForeignKey`; `False` otherwise.

### Field.`one_to_many`

Boolean flag that is `True` if the field has a one-to-many relation, such as a `GenericRelation` or the reverse of a `ForeignKey`; `False` otherwise.

### Field.`one_to_one`

Boolean flag that is `True` if the field has a one-to-one relation, such as a `OneToOneField`; `False` otherwise.

### Field.`related_model`

Points to the model the field relates to. For example, `Author` in `ForeignKey(Author, on_delete=models.CASCADE)`. The `related_model` for a `GenericForeignKey` is always `None`.

## 6.15.3 Model `_meta` API

### class `Options`

The `model_meta` API is at the core of the Django ORM. It enables other parts of the system such as lookups, queries, forms, and the admin to understand the capabilities of each model. The API is accessible through the `_meta` attribute of each model class, which is an instance of an `django.db.models.options.Options` object.

Methods that it provides can be used to:

- Retrieve all field instances of a model
- Retrieve a single field instance of a model by name

## Field access API

### Retrieving a single field instance of a model by name

Options.`get_field` (*field\_name*)

Returns the field instance given a name of a field.

`field_name` can be the name of a field on the model, a field on an abstract or inherited model, or a field defined on another model that points to the model. In the latter case, the `field_name` will be the `related_name` defined by the user or the name automatically generated by Django itself.

*Hidden fields* cannot be retrieved by name.

If a field with the given name is not found a `FieldDoesNotExist` exception will be raised.

```
>>> from django.contrib.auth.models import User

# A field on the model
>>> User._meta.get_field('username')
<django.db.models.fields.CharField: username>

# A field from another model that has a relation with the current model
>>> User._meta.get_field('logentry')
<ManyToOneRel: admin.logentry>

# A non-existent field
>>> User._meta.get_field('does_not_exist')
Traceback (most recent call last):
...
FieldDoesNotExist: User has no field named 'does_not_exist'
```

### Retrieving all field instances of a model

Options.`get_fields` (*include\_parents=True, include\_hidden=False*)

Returns a tuple of fields associated with a model. `get_fields()` accepts two parameters that can be used to control which fields are returned:

**include\_parents** True by default. Recursively includes fields defined on parent classes. If set to `False`, `get_fields()` will only search for fields declared directly on the current model. Fields from models that directly inherit from abstract models or proxy classes are considered to be local, not on the parent.

**include\_hidden** False by default. If set to `True`, `get_fields()` will include fields that are used to back other field's functionality. This will also include any fields that have a `related_name` (such as *ManyToManyField*, or *ForeignKey*) that start with a "+".

```
>>> from django.contrib.auth.models import User
>>> User._meta.get_fields()
(<ManyToOneRel: admin.logentry>,
 <django.db.models.fields.AutoField: id>,
 <django.db.models.fields.CharField: password>,
 <django.db.models.fields.DateTimeField: last_login>)
```

```
<django.db.models.fields.BooleanField: is_superuser>,
<django.db.models.fields.CharField: username>,
<django.db.models.fields.CharField: first_name>,
<django.db.models.fields.CharField: last_name>,
<django.db.models.fields.EmailField: email>,
<django.db.models.fields.BooleanField: is_staff>,
<django.db.models.fields.BooleanField: is_active>,
<django.db.models.fields.DateTimeField: date_joined>,
<django.db.models.fields.related.ManyToManyField: groups>,
<django.db.models.fields.related.ManyToManyField: user_permissions>)

# Also include hidden fields.
>>> User._meta.get_fields(include_hidden=True)
(<ManyToOneRel: auth.user_groups>,
 <ManyToOneRel: auth.user_user_permissions>,
 <ManyToOneRel: admin.logentry>,
 <django.db.models.fields.AutoField: id>,
 <django.db.models.fields.CharField: password>,
 <django.db.models.fields.DateTimeField: last_login>,
 <django.db.models.fields.BooleanField: is_superuser>,
 <django.db.models.fields.CharField: username>,
 <django.db.models.fields.CharField: first_name>,
 <django.db.models.fields.CharField: last_name>,
 <django.db.models.fields.EmailField: email>,
 <django.db.models.fields.BooleanField: is_staff>,
 <django.db.models.fields.BooleanField: is_active>,
 <django.db.models.fields.DateTimeField: date_joined>,
 <django.db.models.fields.related.ManyToManyField: groups>,
 <django.db.models.fields.related.ManyToManyField: user_permissions>)
```

## Migrating from the old API

As part of the formalization of the `Model._meta` API (from the `django.db.models.options.Options` class), a number of methods and properties have been deprecated and will be removed in Django 1.10.

These old APIs can be replicated by either:

- invoking `Options.get_field()`, or;
- invoking `Options.get_fields()` to retrieve a list of all fields, and then filtering this list using the *field attributes* that describe (or retrieve, in the case of `_with_model` variants) the properties of the desired fields.

Although it's possible to make strictly equivalent replacements of the old methods, that might not be the best approach. Taking the time to refactor any field loops to make better use of the new API - and possibly include fields that were previously excluded - will almost certainly result in better code.

Assuming you have a model named `MyModel`, the following substitutions can be made to convert your code to the new API:

- `MyModel._meta.get_field(name)` becomes:

```
f = MyModel._meta.get_field(name)
```

then check if:

- `f.auto_created == False`, because the new `get_field()` API will find “reverse” relations, and:

- `f.is_relation` and `f.related_model` is `None`, because the new `get_field()` API will find *GenericForeignKey* relations.
- `MyModel._meta.get_field_by_name(name)` returns a tuple of these four values with the following replacements:
  - field can be found by `MyModel._meta.get_field(name)`
  - model can be found through the `model` attribute on the field.
  - direct can be found by: `not field.auto_created` or `field.concrete`

The *auto\_created* check excludes all “forward” and “reverse” relations that are created by Django, but this also includes `AutoField` and `OneToOneField` on proxy models. We avoid filtering out these attributes using the *concrete* attribute.

  - m2m can be found through the *many\_to\_many* attribute on the field.

- `MyModel._meta.get_fields_with_model()` becomes:

```
[
    (f, f.model if f.model != MyModel else None)
    for f in MyModel._meta.get_fields()
    if not f.is_relation
       or f.one_to_one
       or (f.many_to_one and f.related_model)
]
```

- `MyModel._meta.get_concrete_fields_with_model()` becomes:

```
[
    (f, f.model if f.model != MyModel else None)
    for f in MyModel._meta.get_fields()
    if f.concrete and (
        not f.is_relation
        or f.one_to_one
        or (f.many_to_one and f.related_model)
    )
]
```

- `MyModel._meta.get_m2m_with_model()` becomes:

```
[
    (f, f.model if f.model != MyModel else None)
    for f in MyModel._meta.get_fields()
    if f.many_to_many and not f.auto_created
]
```

- `MyModel._meta.get_all_related_objects()` becomes:

```
[
    f for f in MyModel._meta.get_fields()
    if (f.one_to_many or f.one_to_one)
    and f.auto_created and not f.concrete
]
```

- `MyModel._meta.get_all_related_objects_with_model()` becomes:

```
[
    (f, f.model if f.model != MyModel else None)
    for f in MyModel._meta.get_fields()
]
```

```
    if (f.one_to_many or f.one_to_one)
        and f.auto_created and not f.concrete
]
```

- `MyModel._meta.get_all_related_many_to_many_objects()` becomes:

```
[
    f for f in MyModel._meta.get_fields(include_hidden=True)
    if f.many_to_many and f.auto_created
]
```

- `MyModel._meta.get_all_related_m2m_objects_with_model()` becomes:

```
[
    (f, f.model if f.model != MyModel else None)
    for f in MyModel._meta.get_fields(include_hidden=True)
    if f.many_to_many and f.auto_created
]
```

- `MyModel._meta.get_all_field_names()` becomes:

```
from itertools import chain
list(set(chain.from_iterable(
    (field.name, field.attname) if hasattr(field, 'attname') else (field.name,)
    for field in MyModel._meta.get_fields()
    # For complete backwards compatibility, you may want to exclude
    # GenericForeignKey from the results.
    if not (field.many_to_one and field.related_model is None)
)))
```

This provides a 100% backwards compatible replacement, ensuring that both field names and attribute names ForeignKeys are included, but fields associated with GenericForeignKeys are not. A simpler version would be:

```
[f.name for f in MyModel._meta.get_fields()]
```

While this isn't 100% backwards compatible, it may be sufficient in many situations.

## 6.15.4 Related objects reference

### class `RelatedManager`

A “related manager” is a manager used in a one-to-many or many-to-many related context. This happens in two cases:

- The “other side” of a *ForeignKey* relation. That is:

```
from django.db import models

class Reporter(models.Model):
    # ...
    pass

class Article(models.Model):
    reporter = models.ForeignKey(Reporter, on_delete=models.CASCADE)
```

In the above example, the methods below will be available on the manager `reporter.article_set`.

- Both sides of a *ManyToManyField* relation:

```
class Topping(models.Model):
    # ...
    pass

class Pizza(models.Model):
    toppings = models.ManyToManyField(Topping)
```

In this example, the methods below will be available both on `topping.pizza_set` and on `pizza.toppings`.

#### **add** (\*objs, bulk=True)

Adds the specified model objects to the related object set.

Example:

```
>>> b = Blog.objects.get(id=1)
>>> e = Entry.objects.get(id=234)
>>> b.entry_set.add(e) # Associates Entry e with Blog b.
```

In the example above, in the case of a *ForeignKey* relationship, *QuerySet.update()* is used to perform the update. This requires the objects to already be saved.

You can use the `bulk=False` argument to instead have the related manager perform the update by calling `e.save()`.

Using `add()` with a many-to-many relationship, however, will not call any `save()` methods, but rather create the relationships using *QuerySet.bulk\_create()*. If you need to execute some custom logic when a relationship is created, listen to the *m2m\_changed* signal.

The `bulk` parameter was added. In older versions, foreign key updates were always done using `save()`. Use `bulk=False` if you require the old behavior.

#### **create** (\*\*kwargs)

Creates a new object, saves it and puts it in the related object set. Returns the newly created object:

```
>>> b = Blog.objects.get(id=1)
>>> e = b.entry_set.create(
...     headline='Hello',
...     body_text='Hi',
...     pub_date=datetime.date(2005, 1, 1)
... )

# No need to call e.save() at this point -- it's already been saved.
```

This is equivalent to (but much simpler than):

```
>>> b = Blog.objects.get(id=1)
>>> e = Entry(
...     blog=b,
...     headline='Hello',
...     body_text='Hi',
...     pub_date=datetime.date(2005, 1, 1)
... )
>>> e.save(force_insert=True)
```

Note that there's no need to specify the keyword argument of the model that defines the relationship. In the above example, we don't pass the parameter `blog` to `create()`. Django figures out that the new `Entry` object's `blog` field should be set to `b`.

**remove (\*objs)**

Removes the specified model objects from the related object set:

```
>>> b = Blog.objects.get(id=1)
>>> e = Entry.objects.get(id=234)
>>> b.entry_set.remove(e) # Disassociates Entry e from Blog b.
```

Similar to `add()`, `e.save()` is called in the example above to perform the update. Using `remove()` with a many-to-many relationship, however, will delete the relationships using `QuerySet.delete()` which means no model `save()` methods are called; listen to the `m2m_changed` signal if you wish to execute custom code when a relationship is deleted.

For `ForeignKey` objects, this method only exists if `null=True`. If the related field can't be set to `None` (NULL), then an object can't be removed from a relation without being added to another. In the above example, removing `e` from `b.entry_set()` is equivalent to doing `e.blog = None`, and because the `blog ForeignKey` doesn't have `null=True`, this is invalid.

For `ForeignKey` objects, this method accepts a `bulk` argument to control how to perform the operation. If `True` (the default), `QuerySet.update()` is used. If `bulk=False`, the `save()` method of each individual model instance is called instead. This triggers the `pre_save` and `post_save` signals and comes at the expense of performance.

**clear()**

Removes all objects from the related object set:

```
>>> b = Blog.objects.get(id=1)
>>> b.entry_set.clear()
```

Note this doesn't delete the related objects – it just disassociates them.

Just like `remove()`, `clear()` is only available on `ForeignKeys` where `null=True` and it also accepts the `bulk` keyword argument.

**set (objs, bulk=True, clear=False)**

Replace the set of related objects:

```
>>> new_list = [obj1, obj2, obj3]
>>> e.related_set.set(new_list)
```

This method accepts a `clear` argument to control how to perform the operation. If `False` (the default), the elements missing from the new set are removed using `remove()` and only the new ones are added. If `clear=True`, the `clear()` method is called instead and the whole set is added at once.

The `bulk` argument is passed on to `add()`.

Note that since `set()` is a compound operation, it is subject to race conditions. For instance, new objects may be added to the database in between the call to `clear()` and the call to `add()`.

---

**Note:** Note that `add()`, `create()`, `remove()`, `clear()`, and `set()` all apply database changes immediately for all types of related fields. In other words, there is no need to call `save()` on either end of the relationship.

Also, if you are using *an intermediate model* for a many-to-many relationship, then the `add()`, `create()`, `remove()`, and `set()` methods are disabled.

---

## Direct Assignment

A related object set can be replaced in bulk with one operation by assigning a new iterable of objects to it:

```
>>> new_list = [obj1, obj2, obj3]
>>> e.related_set = new_list
```

If the foreign key relationship has `null=True`, then the related manager will first disassociate any existing objects in the related set before adding the contents of `new_list`. Otherwise the objects in `new_list` will be added to the existing related object set.

In earlier versions, direct assignment used to perform `clear()` followed by `add()`. It now performs a `set()` with the keyword argument `clear=False`.

Deprecated since version 1.10: Direct assignment is deprecated in favor of the `set()` method:

```
>>> e.related_set.set([obj1, obj2, obj3])
```

This prevents confusion about an assignment resulting in an implicit save.

## 6.15.5 Model class reference

This document covers features of the `Model` class. For more information about models, see *the complete list of Model reference guides*.

### Attributes

#### `objects`

#### `Model.objects`

Each non-abstract `Model` class must have a `Manager` instance added to it. Django ensures that in your model class you have at least a default `Manager` specified. If you don't add your own `Manager`, Django will add an attribute `objects` containing default `Manager` instance. If you add your own `Manager` instance attribute, the default one does not appear. Consider the following example:

```
from django.db import models

class Person(models.Model):
    # Add manager with another name
    people = models.Manager()
```

For more details on model managers see *Managers* and *Retrieving objects*.

## 6.15.6 Model Meta options

This document explains all the possible *metadata options* that you can give your model in its internal class `Meta`.

### Available Meta options

#### `abstract`

#### `Options.abstract`

If `abstract = True`, this model will be an *abstract base class*.

## `app_label`

### Options.`app_label`

If a model is defined outside of an application in `INSTALLED_APPS`, it must declare which app it belongs to:

```
app_label = 'myapp'
```

If you want to represent a model with the format `app_label.object_name` or `app_label.model_name` you can use `model._meta.label` or `model._meta.label_lower` respectively.

## `base_manager_name`

### Options.`base_manager_name`

The name of the manager to use for the model's `_base_manager`.

## `db_table`

### Options.`db_table`

The name of the database table to use for the model:

```
db_table = 'music_album'
```

## Table names

To save you time, Django automatically derives the name of the database table from the name of your model class and the app that contains it. A model's database table name is constructed by joining the model's "app label" – the name you used in `manage.py startapp` – to the model's class name, with an underscore between them.

For example, if you have an app `bookstore` (as created by `manage.py startapp bookstore`), a model defined as `class Book` will have a database table named `bookstore_book`.

To override the database table name, use the `db_table` parameter in `class Meta`.

If your database table name is an SQL reserved word, or contains characters that aren't allowed in Python variable names – notably, the hyphen – that's OK. Django quotes column and table names behind the scenes.

---

### Use lowercase table names for MySQL

It is strongly advised that you use lowercase table names when you override the table name via `db_table`, particularly if you are using the MySQL backend. See the [MySQL notes](#) for more details.

---

---

### Table name quoting for Oracle

In order to meet the 30-char limitation Oracle has on table names, and match the usual conventions for Oracle databases, Django may shorten table names and turn them all-uppercase. To prevent such transformations, use a quoted name as the value for `db_table`:

```
db_table = '"name_left_in_lowercase"'
```

Such quoted names can also be used with Django's other supported database backends; except for Oracle, however, the quotes have no effect. See the [Oracle notes](#) for more details.

---

## db\_tablespace

### Options.db\_tablespace

The name of the *database tablespace* to use for this model. The default is the project's `DEFAULT_TABLESPACE` setting, if set. If the backend doesn't support tablespaces, this option is ignored.

## default\_manager\_name

### Options.default\_manager\_name

The name of the manager to use for the model's `_default_manager`.

## default\_related\_name

### Options.default\_related\_name

The name that will be used by default for the relation from a related object back to this one. The default is `<model_name>_set`.

This option also sets `related_query_name`.

As the reverse name for a field should be unique, be careful if you intend to subclass your model. To work around name collisions, part of the name should contain `'%(app_label)s'` and `'%(model_name)s'`, which are replaced respectively by the name of the application the model is in, and the name of the model, both lowercased. See the paragraph on *related names for abstract models*.

Deprecated since version 1.10: This attribute now affects `related_query_name`. The old query lookup name is deprecated:

```
from django.db import models

class Foo(models.Model):
    pass

class Bar(models.Model):
    foo = models.ForeignKey(Foo)

    class Meta:
        default_related_name = 'bars'
```

```
>>> bar = Bar.objects.get(pk=1)
>>> # Using model name "bar" as lookup string is deprecated.
>>> Foo.objects.get(bar=bar)
>>> # You should use default_related_name "bars".
>>> Foo.objects.get(bars=bar)
```

## get\_latest\_by

### Options.get\_latest\_by

The name of an orderable field in the model, typically a `DateField`, `DateTimeField`, or `IntegerField`. This specifies the default field to use in your model `Manager`'s `latest()` and `earliest()` methods.

Example:

```
get_latest_by = "order_date"
```

See the `latest()` docs for more.

## managed

### Options.managed

Defaults to `True`, meaning Django will create the appropriate database tables in `migrate` or as part of migrations and remove them as part of a `flush` management command. That is, Django *manages* the database tables' lifecycles.

If `False`, no database table creation or deletion operations will be performed for this model. This is useful if the model represents an existing table or a database view that has been created by some other means. This is the *only* difference when `managed=False`. All other aspects of model handling are exactly the same as normal. This includes

1. Adding an automatic primary key field to the model if you don't declare it. To avoid confusion for later code readers, it's recommended to specify all the columns from the database table you are modeling when using unmanaged models.
2. If a model with `managed=False` contains a `ManyToManyField` that points to another unmanaged model, then the intermediate table for the many-to-many join will also not be created. However, the intermediary table between one managed and one unmanaged model *will* be created.

If you need to change this default behavior, create the intermediary table as an explicit model (with `managed` set as needed) and use the `ManyToManyField.through` attribute to make the relation use your custom model.

For tests involving models with `managed=False`, it's up to you to ensure the correct tables are created as part of the test setup.

If you're interested in changing the Python-level behavior of a model class, you *could* use `managed=False` and create a copy of an existing model. However, there's a better approach for that situation: *Proxy models*.

## order\_with\_respect\_to

### Options.order\_with\_respect\_to

Makes this object orderable with respect to the given field, usually a `ForeignKey`. This can be used to make related objects orderable with respect to a parent object. For example, if an `Answer` relates to a `Question` object, and a question has more than one answer, and the order of answers matters, you'd do this:

```
from django.db import models

class Question(models.Model):
    text = models.TextField()
    # ...

class Answer(models.Model):
    question = models.ForeignKey(Question, on_delete=models.CASCADE)
    # ...

class Meta:
    order_with_respect_to = 'question'
```

When `order_with_respect_to` is set, two additional methods are provided to retrieve and to set the order of the related objects: `get_RELATED_order()` and `set_RELATED_order()`, where `RELATED` is

the lowercased model name. For example, assuming that a `Question` object has multiple related `Answer` objects, the list returned contains the primary keys of the related `Answer` objects:

```
>>> question = Question.objects.get(id=1)
>>> question.get_answer_order()
[1, 2, 3]
```

The order of a `Question` object's related `Answer` objects can be set by passing in a list of `Answer` primary keys:

```
>>> question.set_answer_order([3, 1, 2])
```

The related objects also get two methods, `get_next_in_order()` and `get_previous_in_order()`, which can be used to access those objects in their proper order. Assuming the `Answer` objects are ordered by `id`:

```
>>> answer = Answer.objects.get(id=2)
>>> answer.get_next_in_order()
<Answer: 3>
>>> answer.get_previous_in_order()
<Answer: 1>
```

---

### `order_with_respect_to` implicitly sets the `ordering` option

Internally, `order_with_respect_to` adds an additional field/database column named `_order` and sets the model's `ordering` option to this field. Consequently, `order_with_respect_to` and `ordering` cannot be used together, and the ordering added by `order_with_respect_to` will apply whenever you obtain a list of objects of this model.

---

### Changing `order_with_respect_to`

Because `order_with_respect_to` adds a new database column, be sure to make and apply the appropriate migrations if you add or change `order_with_respect_to` after your initial `migrate`.

---

## ordering

### `Options.ordering`

The default ordering for the object, for use when obtaining lists of objects:

```
ordering = ['-order_date']
```

This is a tuple or list of strings. Each string is a field name with an optional “-” prefix, which indicates descending order. Fields without a leading “-” will be ordered ascending. Use the string “?” to order randomly.

For example, to order by a `pub_date` field ascending, use this:

```
ordering = ['pub_date']
```

To order by `pub_date` descending, use this:

```
ordering = ['-pub_date']
```

To order by `pub_date` descending, then by `author` ascending, use this:

```
ordering = ['-pub_date', 'author']
```

Default ordering also affects *aggregation queries*.

**Warning:** Ordering is not a free operation. Each field you add to the ordering incurs a cost to your database. Each foreign key you add will implicitly include all of its default orderings as well.

If a query doesn't have an ordering specified, results are returned from the database in an unspecified order. A particular ordering is guaranteed only when ordering by a set of fields that uniquely identify each object in the results. For example, if a `name` field isn't unique, ordering by it won't guarantee objects with the same name always appear in the same order.

## permissions

### Options.permissions

Extra permissions to enter into the permissions table when creating this object. Add, delete and change permissions are automatically created for each model. This example specifies an extra permission, `can_deliver_pizzas`:

```
permissions = (("can_deliver_pizzas", "Can deliver pizzas"),)
```

This is a list or tuple of 2-tuples in the format `(permission_code, human_readable_permission_name)`.

## default\_permissions

### Options.default\_permissions

Defaults to `('add', 'change', 'delete')`. You may customize this list, for example, by setting this to an empty list if your app doesn't require any of the default permissions. It must be specified on the model before the model is created by *migrate* in order to prevent any omitted permissions from being created.

## proxy

### Options.proxy

If `proxy = True`, a model which subclasses another model will be treated as a *proxy model*.

## required\_db\_features

### Options.required\_db\_features

List of database features that the current connection should have so that the model is considered during the migration phase. For example, if you set this list to `['gis_enabled']`, the model will only be synchronized on GIS-enabled databases. It's also useful to skip some models when testing with several database backends. Avoid relations between models that may or may not be created as the ORM doesn't handle this.

## required\_db\_vendor

### Options.required\_db\_vendor

Name of a supported database vendor that this model is specific to. Current built-in vendor names are: `sqlite`,

postgresql, mysql, oracle. If this attribute is not empty and the current connection vendor doesn't match it, the model will not be synchronized.

### `select_on_save`

#### Options.`select_on_save`

Determines if Django will use the pre-1.6 `django.db.models.Model.save()` algorithm. The old algorithm uses `SELECT` to determine if there is an existing row to be updated. The new algorithm tries an `UPDATE` directly. In some rare cases the `UPDATE` of an existing row isn't visible to Django. An example is the PostgreSQL `ON UPDATE` trigger which returns `NULL`. In such cases the new algorithm will end up doing an `INSERT` even when a row exists in the database.

Usually there is no need to set this attribute. The default is `False`.

See `django.db.models.Model.save()` for more about the old and new saving algorithm.

### `unique_together`

#### Options.`unique_together`

Sets of field names that, taken together, must be unique:

```
unique_together = (("driver", "restaurant"),)
```

This is a tuple of tuples that must be unique when considered together. It's used in the Django admin and is enforced at the database level (i.e., the appropriate `UNIQUE` statements are included in the `CREATE TABLE` statement).

For convenience, `unique_together` can be a single tuple when dealing with a single set of fields:

```
unique_together = ("driver", "restaurant")
```

A `ManyToManyField` cannot be included in `unique_together`. (It's not clear what that would even mean!) If you need to validate uniqueness related to a `ManyToManyField`, try using a signal or an explicit `through` model.

The `ValidationError` raised during model validation when the constraint is violated has the `unique_together` error code.

### `index_together`

#### Options.`index_together`

Sets of field names that, taken together, are indexed:

```
index_together = [
    ["pub_date", "deadline"],
]
```

This list of fields will be indexed together (i.e. the appropriate `CREATE INDEX` statement will be issued.)

For convenience, `index_together` can be a single list when dealing with a single set of fields:

```
index_together = ["pub_date", "deadline"]
```

### `verbose_name`

#### `Options.verbose_name`

A human-readable name for the object, singular:

```
verbose_name = "pizza"
```

If this isn't given, Django will use a munged version of the class name: `CamelCase` becomes `camel case`.

### `verbose_name_plural`

#### `Options.verbose_name_plural`

The plural name for the object:

```
verbose_name_plural = "stories"
```

If this isn't given, Django will use `verbose_name + "s"`.

## Read-only Meta attributes

### `label`

#### `Options.label`

Representation of the object, returns `app_label.object_name`, e.g. `'polls.Question'`.

### `label_lower`

#### `Options.label_lower`

Representation of the model, returns `app_label.model_name`, e.g. `'polls.question'`.

## 6.15.7 Model instance reference

This document describes the details of the `Model` API. It builds on the material presented in the *model* and *database query* guides, so you'll probably want to read and understand those documents before reading this one.

Throughout this reference we'll use the *example Weblog models* presented in the *database query guide*.

### Creating objects

To create a new instance of a model, just instantiate it like any other Python class:

```
class Model (**kwargs)
```

The keyword arguments are simply the names of the fields you've defined on your model. Note that instantiating a model in no way touches your database; for that, you need to `save()`.

---

**Note:** You may be tempted to customize the model by overriding the `__init__` method. If you do so, however, take care not to change the calling signature as any change may prevent the model instance from being saved. Rather than overriding `__init__`, try using one of these approaches:

1. Add a classmethod on the model class:

```

from django.db import models

class Book(models.Model):
    title = models.CharField(max_length=100)

    @classmethod
    def create(cls, title):
        book = cls(title=title)
        # do something with the book
        return book

book = Book.create("Pride and Prejudice")

```

2. Add a method on a custom manager (usually preferred):

```

class BookManager(models.Manager):
    def create_book(self, title):
        book = self.create(title=title)
        # do something with the book
        return book

class Book(models.Model):
    title = models.CharField(max_length=100)

    objects = BookManager()

book = Book.objects.create_book("Pride and Prejudice")

```

## Customizing model loading

`classmethod Model.from_db(db, field_names, values)`

The `from_db()` method can be used to customize model instance creation when loading from the database.

The `db` argument contains the database alias for the database the model is loaded from, `field_names` contains the names of all loaded fields, and `values` contains the loaded values for each field in `field_names`. The `field_names` are in the same order as the `values`. If all of the model's fields are present, then `values` are guaranteed to be in the order `__init__()` expects them. That is, the instance can be created by `cls(*values)`. If any fields are deferred, they won't appear in `field_names`. In that case, assign a value of `django.db.models.DEFERRED` to each of the missing fields.

In addition to creating the new model, the `from_db()` method must set the `adding` and `db` flags in the new instance's `_state` attribute.

Below is an example showing how to record the initial values of fields that are loaded from the database:

```

from django.db.models import DEFERRED

@classmethod
def from_db(cls, db, field_names, values):
    # Default implementation of from_db() (subject to change and could
    # be replaced with super()).
    if len(values) != len(cls._meta.concrete_fields):
        values = list(values)
        values.reverse()
        values = [

```

```
        values.pop() if f.attname in field_names else DEFERRED
        for f in cls._meta.concrete_fields
    ]
    instance = cls(*values)
    instance._state.adding = False
    instance._state.db = db
    # customization to store the original field values on the instance
    instance._loaded_values = dict(zip(field_names, values))
    return instance

def save(self, *args, **kwargs):
    # Check how the current values differ from ._loaded_values. For example,
    # prevent changing the creator_id of the model. (This example doesn't
    # support cases where 'creator_id' is deferred).
    if not self._state.adding and (
        self.creator_id != self._loaded_values['creator_id']):
        raise ValueError("Updating the value of creator isn't allowed")
    super(...).save(*args, **kwargs)
```

The example above shows a full `from_db()` implementation to clarify how that is done. In this case it would of course be possible to just use `super()` call in the `from_db()` method.

In older versions, you could check if all fields were loaded by consulting `cls._deferred`. This attribute is removed and `django.db.models.DEFERRED` is new.

## Refreshing objects from database

If you delete a field from a model instance, accessing it again reloads the value from the database:

```
>>> obj = MyModel.objects.first()
>>> del obj.field
>>> obj.field # Loads the field from the database
```

In older versions, accessing a deleted field raised `AttributeError` instead of reloading it.

`Model.refresh_from_db(using=None, fields=None)`

If you need to reload a model's values from the database, you can use the `refresh_from_db()` method. When this method is called without arguments the following is done:

1. All non-deferred fields of the model are updated to the values currently present in the database.
2. The previously loaded related instances for which the relation's value is no longer valid are removed from the reloaded instance. For example, if you have a foreign key from the reloaded instance to another model with name `Author`, then if `obj.author_id != obj.author.id`, `obj.author` will be thrown away, and when next accessed it will be reloaded with the value of `obj.author_id`.

Only fields of the model are reloaded from the database. Other database-dependent values such as annotations aren't reloaded. Any `@cached_property` attributes aren't cleared either.

The reloading happens from the database the instance was loaded from, or from the default database if the instance wasn't loaded from the database. The `using` argument can be used to force the database used for reloading.

It is possible to force the set of fields to be loaded by using the `fields` argument.

For example, to test that an `update()` call resulted in the expected update, you could write a test similar to this:

```
def test_update_result(self):
    obj = MyModel.objects.create(val=1)
```

```
MyModel.objects.filter(pk=obj.pk).update(val=F('val') + 1)
# At this point obj.val is still 1, but the value in the database
# was updated to 2. The object's updated value needs to be reloaded
# from the database.
obj.refresh_from_db()
self.assertEqual(obj.val, 2)
```

Note that when deferred fields are accessed, the loading of the deferred field's value happens through this method. Thus it is possible to customize the way deferred loading happens. The example below shows how one can reload all of the instance's fields when a deferred field is reloaded:

```
class ExampleModel(models.Model):
    def refresh_from_db(self, using=None, fields=None, **kwargs):
        # fields contains the name of the deferred field to be
        # loaded.
        if fields is not None:
            fields = set(fields)
            deferred_fields = self.get_deferred_fields()
            # If any deferred field is going to be loaded
            if fields.intersection(deferred_fields):
                # then load all of them
                fields = fields.union(deferred_fields)
            super(ExampleModel, self).refresh_from_db(using, fields, **kwargs)
```

`Model.get_deferred_fields()`

A helper method that returns a set containing the attribute names of all those fields that are currently deferred for this model.

## Validating objects

There are three steps involved in validating a model:

1. Validate the model fields - `Model.clean_fields()`
2. Validate the model as a whole - `Model.clean()`
3. Validate the field uniqueness - `Model.validate_unique()`

All three steps are performed when you call a model's `full_clean()` method.

When you use a `ModelForm`, the call to `is_valid()` will perform these validation steps for all the fields that are included on the form. See the [ModelForm documentation](#) for more information. You should only need to call a model's `full_clean()` method if you plan to handle validation errors yourself, or if you have excluded fields from the `ModelForm` that require validation.

`Model.full_clean(exclude=None, validate_unique=True)`

This method calls `Model.clean_fields()`, `Model.clean()`, and `Model.validate_unique()` (if `validate_unique` is `True`), in that order and raises a `ValidationError` that has a `message_dict` attribute containing errors from all three stages.

The optional `exclude` argument can be used to provide a list of field names that can be excluded from validation and cleaning. `ModelForm` uses this argument to exclude fields that aren't present on your form from being validated since any errors raised could not be corrected by the user.

Note that `full_clean()` will *not* be called automatically when you call your model's `save()` method. You'll need to call it manually when you want to run one-step model validation for your own manually created models. For example:

```
from django.core.exceptions import ValidationError
try:
    article.full_clean()
except ValidationError as e:
    # Do something based on the errors contained in e.message_dict.
    # Display them to a user, or handle them programmatically.
    pass
```

The first step `full_clean()` performs is to clean each individual field.

`Model.clean_fields` (*exclude=None*)

This method will validate all fields on your model. The optional `exclude` argument lets you provide a list of field names to exclude from validation. It will raise a `ValidationError` if any fields fail validation.

The second step `full_clean()` performs is to call `Model.clean()`. This method should be overridden to perform custom validation on your model.

`Model.clean()`

This method should be used to provide custom model validation, and to modify attributes on your model if desired. For instance, you could use it to automatically provide a value for a field, or to do validation that requires access to more than a single field:

```
import datetime
from django.core.exceptions import ValidationError
from django.db import models
from django.utils.translation import ugettext_lazy as _

class Article(models.Model):
    ...
    def clean(self):
        # Don't allow draft entries to have a pub_date.
        if self.status == 'draft' and self.pub_date is not None:
            raise ValidationError(_('Draft entries may not have a publication date.'))
        # Set the pub_date for published items if it hasn't been set already.
        if self.status == 'published' and self.pub_date is None:
            self.pub_date = datetime.date.today()
```

Note, however, that like `Model.full_clean()`, a model's `clean()` method is not invoked when you call your model's `save()` method.

In the above example, the `ValidationError` exception raised by `Model.clean()` was instantiated with a string, so it will be stored in a special error dictionary key, `NON_FIELD_ERRORS`. This key is used for errors that are tied to the entire model instead of to a specific field:

```
from django.core.exceptions import ValidationError, NON_FIELD_ERRORS
try:
    article.full_clean()
except ValidationError as e:
    non_field_errors = e.message_dict[NON_FIELD_ERRORS]
```

To assign exceptions to a specific field, instantiate the `ValidationError` with a dictionary, where the keys are the field names. We could update the previous example to assign the error to the `pub_date` field:

```
class Article(models.Model):
    ...
    def clean(self):
        # Don't allow draft entries to have a pub_date.
```

```

    if self.status == 'draft' and self.pub_date is not None:
        raise ValidationError({'pub_date': _('Draft entries may not have a_
↪publication date.')})
    ...

```

If you detect errors in multiple fields during `Model.clean()`, you can also pass a dictionary mapping field names to errors:

```

raise ValidationError({
    'title': ValidationError(_('Missing title.'), code='required'),
    'pub_date': ValidationError(_('Invalid date.'), code='invalid'),
})

```

Finally, `full_clean()` will check any unique constraints on your model.

`Model.validate_unique` (*exclude=None*)

This method is similar to `clean_fields()`, but validates all uniqueness constraints on your model instead of individual field values. The optional `exclude` argument allows you to provide a list of field names to exclude from validation. It will raise a `ValidationError` if any fields fail validation.

Note that if you provide an `exclude` argument to `validate_unique()`, any *unique\_together* constraint involving one of the fields you provided will not be checked.

## Saving objects

To save an object back to the database, call `save()`:

`Model.save` (*force\_insert=False, force\_update=False, using=DEFAULT\_DB\_ALIAS, update\_fields=None*)

If you want customized saving behavior, you can override this `save()` method. See *Overriding predefined model methods* for more details.

The model save process also has some subtleties; see the sections below.

## Auto-incrementing primary keys

If a model has an `AutoField` — an auto-incrementing primary key — then that auto-incremented value will be calculated and saved as an attribute on your object the first time you call `save()`:

```

>>> b2 = Blog(name='Cheddar Talk', tagline='Thoughts on cheese.')
>>> b2.id      # Returns None, because b doesn't have an ID yet.
>>> b2.save()
>>> b2.id      # Returns the ID of your new object.

```

There's no way to tell what the value of an ID will be before you call `save()`, because that value is calculated by your database, not by Django.

For convenience, each model has an `AutoField` named `id` by default unless you explicitly specify `primary_key=True` on a field in your model. See the documentation for `AutoField` for more details.

## The `pk` property

`Model.pk`

Regardless of whether you define a primary key field yourself, or let Django supply one for you, each model will have a property called `pk`. It behaves like a normal attribute on the model, but is actually an alias for whichever attribute is the primary key field for the model. You can read and set this value, just as you would for any other attribute, and it will update the correct field in the model.

### Explicitly specifying auto-primary-key values

If a model has an `AutoField` but you want to define a new object's ID explicitly when saving, just define it explicitly before saving, rather than relying on the auto-assignment of the ID:

```
>>> b3 = Blog(id=3, name='Cheddar Talk', tagline='Thoughts on cheese.')
>>> b3.id      # Returns 3.
>>> b3.save()
>>> b3.id      # Returns 3.
```

If you assign auto-primary-key values manually, make sure not to use an already-existing primary-key value! If you create a new object with an explicit primary-key value that already exists in the database, Django will assume you're changing the existing record rather than creating a new one.

Given the above 'Cheddar Talk' blog example, this example would override the previous record in the database:

```
b4 = Blog(id=3, name='Not Cheddar', tagline='Anything but cheese.')
b4.save() # Overrides the previous blog with ID=3!
```

See *How Django knows to UPDATE vs. INSERT*, below, for the reason this happens.

Explicitly specifying auto-primary-key values is mostly useful for bulk-saving objects, when you're confident you won't have primary-key collision.

### What happens when you save?

When you save an object, Django performs the following steps:

1. **Emit a pre-save signal.** The `pre_save` signal is sent, allowing any functions listening for that signal to do something.
2. **Preprocess the data.** Each field's `pre_save()` method is called to perform any automated data modification that's needed. For example, the date/time fields override `pre_save()` to implement `auto_now_add` and `auto_now`.
3. **Prepare the data for the database.** Each field's `get_db_prep_save()` method is asked to provide its current value in a data type that can be written to the database.

Most fields don't require data preparation. Simple data types, such as integers and strings, are 'ready to write' as a Python object. However, more complex data types often require some modification.

For example, `DateField` fields use a Python `datetime` object to store data. Databases don't store `datetime` objects, so the field value must be converted into an ISO-compliant date string for insertion into the database.

4. **Insert the data into the database.** The preprocessed, prepared data is composed into an SQL statement for insertion into the database.
5. **Emit a post-save signal.** The `post_save` signal is sent, allowing any functions listening for that signal to do something.

## How Django knows to UPDATE vs. INSERT

You may have noticed Django database objects use the same `save()` method for creating and changing objects. Django abstracts the need to use `INSERT` or `UPDATE` SQL statements. Specifically, when you call `save()`, Django follows this algorithm:

- If the object's primary key attribute is set to a value that evaluates to `True` (i.e., a value other than `None` or the empty string), Django executes an `UPDATE`.
- If the object's primary key attribute is *not* set or if the `UPDATE` didn't update anything, Django executes an `INSERT`.

The one gotcha here is that you should be careful not to specify a primary-key value explicitly when saving new objects, if you cannot guarantee the primary-key value is unused. For more on this nuance, see [Explicitly specifying auto-primary-key values](#) above and [Forcing an INSERT or UPDATE](#) below.

In Django 1.5 and earlier, Django did a `SELECT` when the primary key attribute was set. If the `SELECT` found a row, then Django did an `UPDATE`, otherwise it did an `INSERT`. The old algorithm results in one more query in the `UPDATE` case. There are some rare cases where the database doesn't report that a row was updated even if the database contains a row for the object's primary key value. An example is the PostgreSQL `ON UPDATE` trigger which returns `NULL`. In such cases it is possible to revert to the old algorithm by setting the `select_on_save` option to `True`.

## Forcing an INSERT or UPDATE

In some rare circumstances, it's necessary to be able to force the `save()` method to perform an SQL `INSERT` and not fall back to doing an `UPDATE`. Or vice-versa: update, if possible, but not insert a new row. In these cases you can pass the `force_insert=True` or `force_update=True` parameters to the `save()` method. Obviously, passing both parameters is an error: you cannot both insert *and* update at the same time!

It should be very rare that you'll need to use these parameters. Django will almost always do the right thing and trying to override that will lead to errors that are difficult to track down. This feature is for advanced use only.

Using `update_fields` will force an update similarly to `force_update`.

## Updating attributes based on existing fields

Sometimes you'll need to perform a simple arithmetic task on a field, such as incrementing or decrementing the current value. The obvious way to achieve this is to do something like:

```
>>> product = Product.objects.get(name='Venezuelan Beaver Cheese')
>>> product.number_sold += 1
>>> product.save()
```

If the old `number_sold` value retrieved from the database was 10, then the value of 11 will be written back to the database.

The process can be made robust, *avoiding a race condition*, as well as slightly faster by expressing the update relative to the original field value, rather than as an explicit assignment of a new value. Django provides *F expressions* for performing this kind of relative update. Using *F expressions*, the previous example is expressed as:

```
>>> from django.db.models import F
>>> product = Product.objects.get(name='Venezuelan Beaver Cheese')
>>> product.number_sold = F('number_sold') + 1
>>> product.save()
```

For more details, see the documentation on *F expressions* and their *use in update queries*.

## Specifying which fields to save

If `save()` is passed a list of field names in keyword argument `update_fields`, only the fields named in that list will be updated. This may be desirable if you want to update just one or a few fields on an object. There will be a slight performance benefit from preventing all of the model fields from being updated in the database. For example:

```
product.name = 'Name changed again'
product.save(update_fields=['name'])
```

The `update_fields` argument can be any iterable containing strings. An empty `update_fields` iterable will skip the save. A value of `None` will perform an update on all fields.

Specifying `update_fields` will force an update.

When saving a model fetched through deferred model loading (`only()` or `defer()`) only the fields loaded from the DB will get updated. In effect there is an automatic `update_fields` in this case. If you assign or change any deferred field value, the field will be added to the updated fields.

## Deleting objects

`Model.delete()` (*using=DEFAULT\_DB\_ALIAS, keep\_parents=False*)

Issues an SQL `DELETE` for the object. This only deletes the object in the database; the Python instance will still exist and will still have data in its fields. This method returns the number of objects deleted and a dictionary with the number of deletions per object type.

For more details, including how to delete objects in bulk, see [Deleting objects](#).

If you want customized deletion behavior, you can override the `delete()` method. See [Overriding predefined model methods](#) for more details.

Sometimes with [multi-table inheritance](#) you may want to delete only a child model's data. Specifying `keep_parents=True` will keep the parent model's data.

The `keep_parents` parameter was added.

The return value describing the number of objects deleted was added.

## Pickling objects

When you `pickle` a model, its current state is pickled. When you unpickle it, it'll contain the model instance at the moment it was pickled, rather than the data that's currently in the database.

---

### You can't share pickles between versions

Pickles of models are only valid for the version of Django that was used to generate them. If you generate a pickle using Django version N, there is no guarantee that pickle will be readable with Django version N+1. Pickles should not be used as part of a long-term archival strategy.

Since pickle compatibility errors can be difficult to diagnose, such as silently corrupted objects, a `RuntimeWarning` is raised when you try to unpickle a model in a Django version that is different than the one in which it was pickled.

---

## Other model instance methods

A few object methods have special purposes.

`__str__()`

Model.`__str__()`

The `__str__()` method is called whenever you call `str()` on an object. Django uses `str(obj)` in a number of places. Most notably, to display an object in the Django admin site and as the value inserted into a template when it displays an object. Thus, you should always return a nice, human-readable representation of the model from the `__str__()` method.

For example:

```
from django.db import models
from django.utils.encoding import python_2_unicode_compatible

@python_2_unicode_compatible # only if you need to support Python 2
class Person(models.Model):
    first_name = models.CharField(max_length=50)
    last_name = models.CharField(max_length=50)

    def __str__(self):
        return '%s %s' % (self.first_name, self.last_name)
```

If you'd like compatibility with Python 2, you can decorate your model class with `python_2_unicode_compatible()` as shown above.

`__eq__()`

Model.`__eq__()`

The equality method is defined such that instances with the same primary key value and the same concrete class are considered equal, except that instances with a primary key value of `None` aren't equal to anything except themselves. For proxy models, concrete class is defined as the model's first non-proxy parent; for all other models it's simply the model's class.

For example:

```
from django.db import models

class MyModel(models.Model):
    id = models.AutoField(primary_key=True)

class MyProxyModel(MyModel):
    class Meta:
        proxy = True

class MultitableInherited(MyModel):
    pass

# Primary keys compared
MyModel(id=1) == MyModel(id=1)
MyModel(id=1) != MyModel(id=2)
# Primary keys are None
MyModel(id=None) != MyModel(id=None)
# Same instance
instance = MyModel(id=None)
instance == instance
# Proxy model
```

```
MyModel(id=1) == MyProxyModel(id=1)
# Multi-table inheritance
MyModel(id=1) != MultitableInherited(id=1)
```

## `__hash__()`

`Model.__hash__()`

The `__hash__()` method is based on the instance's primary key value. It is effectively `hash(obj.pk)`. If the instance doesn't have a primary key value then a `TypeError` will be raised (otherwise the `__hash__()` method would return different values before and after the instance is saved, but changing the `__hash__()` value of an instance is forbidden in Python).

## `get_absolute_url()`

`Model.get_absolute_url()`

Define a `get_absolute_url()` method to tell Django how to calculate the canonical URL for an object. To callers, this method should appear to return a string that can be used to refer to the object over HTTP.

For example:

```
def get_absolute_url(self):
    return "/people/%i/" % self.id
```

While this code is correct and simple, it may not be the most portable way to write this kind of method. The `reverse()` function is usually the best approach.

For example:

```
def get_absolute_url(self):
    from django.urls import reverse
    return reverse('people.views.details', args=[str(self.id)])
```

One place Django uses `get_absolute_url()` is in the admin app. If an object defines this method, the object-editing page will have a “View on site” link that will jump you directly to the object's public view, as given by `get_absolute_url()`.

Similarly, a couple of other bits of Django, such as the *syndication feed framework*, use `get_absolute_url()` when it is defined. If it makes sense for your model's instances to each have a unique URL, you should define `get_absolute_url()`.

**Warning:** You should avoid building the URL from unvalidated user input, in order to reduce possibilities of link or redirect poisoning:

```
def get_absolute_url(self):
    return '%s/' % self.name
```

If `self.name` is  `'/example.com'` this returns  `'//example.com/'` which, in turn, is a valid schema relative URL but not the expected  `'/%2Fexample.com/'`.

It's good practice to use `get_absolute_url()` in templates, instead of hard-coding your objects' URLs. For example, this template code is bad:

```
<!-- BAD template code. Avoid! -->
<a href="/people/{{ object.id }}/">{{ object.name }}</a>
```

This template code is much better:

```
<a href="{{ object.get_absolute_url }}">{{ object.name }}</a>
```

The logic here is that if you change the URL structure of your objects, even for something simple such as correcting a spelling error, you don't want to have to track down every place that the URL might be created. Specify it once, in `get_absolute_url()` and have all your other code call that one place.

**Note:** The string you return from `get_absolute_url()` **must** contain only ASCII characters (required by the URI specification, [RFC 2396](#)) and be URL-encoded, if necessary.

Code and templates calling `get_absolute_url()` should be able to use the result directly without any further processing. You may wish to use the `django.utils.encoding.iri_to_uri()` function to help with this if you are using unicode strings containing characters outside the ASCII range at all.

## Extra instance methods

In addition to `save()`, `delete()`, a model object might have some of the following methods:

`Model.get_FOO_display()`

For every field that has `choices` set, the object will have a `get_FOO_display()` method, where FOO is the name of the field. This method returns the “human-readable” value of the field.

For example:

```
from django.db import models

class Person(models.Model):
    SHIRT_SIZES = (
        ('S', 'Small'),
        ('M', 'Medium'),
        ('L', 'Large'),
    )
    name = models.CharField(max_length=60)
    shirt_size = models.CharField(max_length=2, choices=SHIRT_SIZES)
```

```
>>> p = Person(name="Fred Flintstone", shirt_size="L")
>>> p.save()
>>> p.shirt_size
'L'
>>> p.get_shirt_size_display()
'Large'
```

`Model.get_next_by_FOO(**kwargs)`

`Model.get_previous_by_FOO(**kwargs)`

For every `DateField` and `DateTimeField` that does not have `null=True`, the object will have `get_next_by_FOO()` and `get_previous_by_FOO()` methods, where FOO is the name of the field. This returns the next and previous object with respect to the date field, raising a `DoesNotExist` exception when appropriate.

Both of these methods will perform their queries using the default manager for the model. If you need to emulate filtering used by a custom manager, or want to perform one-off custom filtering, both methods also accept optional keyword arguments, which should be in the format described in *Field lookups*.

Note that in the case of identical date values, these methods will use the primary key as a tie-breaker. This guarantees that no records are skipped or duplicated. That also means you cannot use those methods on unsaved objects.

## Other attributes

### DoesNotExist

#### exception `Model.DoesNotExist`

This exception is raised by the ORM in a couple places, for example by `QuerySet.get()` when an object is not found for the given query parameters.

Django provides a `DoesNotExist` exception as an attribute of each model class to identify the class of object that could not be found and to allow you to catch a particular model class with `try/except`. The exception is a subclass of `django.core.exceptions.ObjectDoesNotExist`.

## 6.15.8 QuerySet API reference

This document describes the details of the `QuerySet` API. It builds on the material presented in the *model* and *database query* guides, so you'll probably want to read and understand those documents before reading this one.

Throughout this reference we'll use the *example Weblog models* presented in the *database query guide*.

### When QuerySets are evaluated

Internally, a `QuerySet` can be constructed, filtered, sliced, and generally passed around without actually hitting the database. No database activity actually occurs until you do something to evaluate the queryset.

You can evaluate a `QuerySet` in the following ways:

- **Iteration.** A `QuerySet` is iterable, and it executes its database query the first time you iterate over it. For example, this will print the headline of all entries in the database:

```
for e in Entry.objects.all():
    print(e.headline)
```

Note: Don't use this if all you want to do is determine if at least one result exists. It's more efficient to use `exists()`.

- **Slicing.** As explained in *Limiting QuerySets*, a `QuerySet` can be sliced, using Python's array-slicing syntax. Slicing an unevaluated `QuerySet` usually returns another unevaluated `QuerySet`, but Django will execute the database query if you use the "step" parameter of slice syntax, and will return a list. Slicing a `QuerySet` that has been evaluated also returns a list.

Also note that even though slicing an unevaluated `QuerySet` returns another unevaluated `QuerySet`, modifying it further (e.g., adding more filters, or modifying ordering) is not allowed, since that does not translate well into SQL and it would not have a clear meaning either.

- **Pickling/Caching.** See the following section for details of what is involved when *pickling QuerySets*. The important thing for the purposes of this section is that the results are read from the database.
- **repr().** A `QuerySet` is evaluated when you call `repr()` on it. This is for convenience in the Python interactive interpreter, so you can immediately see your results when using the API interactively.

- **len()**. A `QuerySet` is evaluated when you call `len()` on it. This, as you might expect, returns the length of the result list.

Note: If you only need to determine the number of records in the set (and don't need the actual objects), it's much more efficient to handle a count at the database level using SQL's `SELECT COUNT(*)`. Django provides a `count()` method for precisely this reason.

- **list()**. Force evaluation of a `QuerySet` by calling `list()` on it. For example:

```
entry_list = list(Entry.objects.all())
```

- **bool()**. Testing a `QuerySet` in a boolean context, such as using `bool()`, `or`, `and` or an `if` statement, will cause the query to be executed. If there is at least one result, the `QuerySet` is `True`, otherwise `False`. For example:

```
if Entry.objects.filter(headline="Test"):
    print("There is at least one Entry with the headline Test")
```

Note: If you only want to determine if at least one result exists (and don't need the actual objects), it's more efficient to use `exists()`.

## Pickling QuerySets

If you `pickle` a `QuerySet`, this will force all the results to be loaded into memory prior to pickling. Pickling is usually used as a precursor to caching and when the cached queryset is reloaded, you want the results to already be present and ready for use (reading from the database can take some time, defeating the purpose of caching). This means that when you unpickle a `QuerySet`, it contains the results at the moment it was pickled, rather than the results that are currently in the database.

If you only want to pickle the necessary information to recreate the `QuerySet` from the database at a later time, pickle the `query` attribute of the `QuerySet`. You can then recreate the original `QuerySet` (without any results loaded) using some code like this:

```
>>> import pickle
>>> query = pickle.loads(s)      # Assuming 's' is the pickled string.
>>> qs = MyModel.objects.all()
>>> qs.query = query            # Restore the original 'query'.
```

The `query` attribute is an opaque object. It represents the internals of the query construction and is not part of the public API. However, it is safe (and fully supported) to pickle and unpickle the attribute's contents as described here.

## You can't share pickles between versions

Pickles of `QuerySets` are only valid for the version of Django that was used to generate them. If you generate a pickle using Django version N, there is no guarantee that pickle will be readable with Django version N+1. Pickles should not be used as part of a long-term archival strategy.

Since pickle compatibility errors can be difficult to diagnose, such as silently corrupted objects, a `RuntimeWarning` is raised when you try to unpickle a queryset in a Django version that is different than the one in which it was pickled.

## QuerySet API

Here's the formal declaration of a `QuerySet`:

**class `QuerySet`** (*model=None, query=None, using=None*)

Usually when you'll interact with a `QuerySet` you'll use it by *chaining filters*. To make this work, most `QuerySet` methods return new querysets. These methods are covered in detail later in this section.

The `QuerySet` class has two public attributes you can use for introspection:

**ordered**

True if the `QuerySet` is ordered — i.e. has an `order_by()` clause or a default ordering on the model. False otherwise.

**db**

The database that will be used if this query is executed now.

---

**Note:** The `query` parameter to `QuerySet` exists so that specialized query subclasses such as `GeoQuerySet` can reconstruct internal query state. The value of the parameter is an opaque representation of that query state and is not part of a public API. To put it simply: if you need to ask, you don't need to use it.

---

## Methods that return new `QuerySets`

Django provides a range of `QuerySet` refinement methods that modify either the types of results returned by the `QuerySet` or the way its SQL query is executed.

### `filter()`

**filter** (*\*\*kwargs*)

Returns a new `QuerySet` containing objects that match the given lookup parameters.

The lookup parameters (*\*\*kwargs*) should be in the format described in *Field lookups* below. Multiple parameters are joined via AND in the underlying SQL statement.

If you need to execute more complex queries (for example, queries with OR statements), you can use *Q objects*.

### `exclude()`

**exclude** (*\*\*kwargs*)

Returns a new `QuerySet` containing objects that do *not* match the given lookup parameters.

The lookup parameters (*\*\*kwargs*) should be in the format described in *Field lookups* below. Multiple parameters are joined via AND in the underlying SQL statement, and the whole thing is enclosed in a NOT().

This example excludes all entries whose `pub_date` is later than 2005-1-3 AND whose headline is “Hello”:

```
Entry.objects.exclude(pub_date__gt=datetime.date(2005, 1, 3), headline='Hello')
```

In SQL terms, that evaluates to:

```
SELECT ...
WHERE NOT (pub_date > '2005-1-3' AND headline = 'Hello')
```

This example excludes all entries whose `pub_date` is later than 2005-1-3 OR whose headline is “Hello”:

```
Entry.objects.exclude(pub_date__gt=datetime.date(2005, 1, 3)).exclude(headline='Hello')
↪')
```

In SQL terms, that evaluates to:

```
SELECT ...
WHERE NOT pub_date > '2005-1-3'
AND NOT headline = 'Hello'
```

Note the second example is more restrictive.

If you need to execute more complex queries (for example, queries with OR statements), you can use *Q objects*.

## annotate()

**annotate** (\*args, \*\*kwargs)

Annotates each object in the `QuerySet` with the provided list of *query expressions*. An expression may be a simple value, a reference to a field on the model (or any related models), or an aggregate expression (averages, sums, etc.) that has been computed over the objects that are related to the objects in the `QuerySet`.

Each argument to `annotate()` is an annotation that will be added to each object in the `QuerySet` that is returned.

The aggregation functions that are provided by Django are described in *Aggregation Functions* below.

Annotations specified using keyword arguments will use the keyword as the alias for the annotation. Anonymous arguments will have an alias generated for them based upon the name of the aggregate function and the model field that is being aggregated. Only aggregate expressions that reference a single field can be anonymous arguments. Everything else must be a keyword argument.

For example, if you were manipulating a list of blogs, you may want to determine how many entries have been made in each blog:

```
>>> from django.db.models import Count
>>> q = Blog.objects.annotate(Count('entry'))
# The name of the first blog
>>> q[0].name
'Blogasaurus'
# The number of entries on the first blog
>>> q[0].entry__count
42
```

The `Blog` model doesn't define an `entry__count` attribute by itself, but by using a keyword argument to specify the aggregate function, you can control the name of the annotation:

```
>>> q = Blog.objects.annotate(number_of_entries=Count('entry'))
# The number of entries on the first blog, using the name provided
>>> q[0].number_of_entries
42
```

For an in-depth discussion of aggregation, see *the topic guide on Aggregation*.

## order\_by()

**order\_by** (\*fields)

By default, results returned by a `QuerySet` are ordered by the ordering tuple given by the `ordering` option in the model's `Meta`. You can override this on a per-`QuerySet` basis by using the `order_by` method.

Example:

```
Entry.objects.filter(pub_date__year=2005).order_by('-pub_date', 'headline')
```

The result above will be ordered by `pub_date` descending, then by `headline` ascending. The negative sign in front of `"-pub_date"` indicates *descending* order. Ascending order is implied. To order randomly, use `"?"`, like so:

```
Entry.objects.order_by('?')
```

Note: `order_by('?')` queries may be expensive and slow, depending on the database backend you're using.

To order by a field in a different model, use the same syntax as when you are querying across model relations. That is, the name of the field, followed by a double underscore (`__`), followed by the name of the field in the new model, and so on for as many models as you want to join. For example:

```
Entry.objects.order_by('blog__name', 'headline')
```

If you try to order by a field that is a relation to another model, Django will use the default ordering on the related model, or order by the related model's primary key if there is no *Meta.ordering* specified. For example, since the `Blog` model has no default ordering specified:

```
Entry.objects.order_by('blog')
```

...is identical to:

```
Entry.objects.order_by('blog__id')
```

If `Blog` had `ordering = ['name']`, then the first queryset would be identical to:

```
Entry.objects.order_by('blog__name')
```

You can also order by *query expressions* by calling `asc()` or `desc()` on the expression:

```
Entry.objects.order_by(Coalesce('summary', 'headline').desc())
```

Be cautious when ordering by fields in related models if you are also using `distinct()`. See the note in `distinct()` for an explanation of how related model ordering can change the expected results.

---

**Note:** It is permissible to specify a multi-valued field to order the results by (for example, a *ManyToManyField* field, or the reverse relation of a *ForeignKey* field).

Consider this case:

```
class Event (Model):
    parent = models.ForeignKey(
        'self',
        on_delete=models.CASCADE,
        related_name='children',
    )
    date = models.DateField()

Event.objects.order_by('children__date')
```

Here, there could potentially be multiple ordering data for each `Event`; each `Event` with multiple `children` will be returned multiple times into the new `QuerySet` that `order_by()` creates. In other words, using `order_by()` on the `QuerySet` could return more items than you were working on to begin with - which is probably neither expected nor useful.

Thus, take care when using multi-valued field to order the results. **If** you can be sure that there will only be one ordering piece of data for each of the items you're ordering, this approach should not present problems. If not, make sure the results are what you expect.

There's no way to specify whether ordering should be case sensitive. With respect to case-sensitivity, Django will order results however your database backend normally orders them.

You can order by a field converted to lowercase with `Lower` which will achieve case-consistent ordering:

```
Entry.objects.order_by(Lower('headline').desc())
```

If you don't want any ordering to be applied to a query, not even the default ordering, call `order_by()` with no parameters.

You can tell if a query is ordered or not by checking the `QuerySet.ordered` attribute, which will be `True` if the `QuerySet` has been ordered in any way.

Each `order_by()` call will clear any previous ordering. For example, this query will be ordered by `pub_date` and not `headline`:

```
Entry.objects.order_by('headline').order_by('pub_date')
```

**Warning:** Ordering is not a free operation. Each field you add to the ordering incurs a cost to your database. Each foreign key you add will implicitly include all of its default orderings as well.

If a query doesn't have an ordering specified, results are returned from the database in an unspecified order. A particular ordering is guaranteed only when ordering by a set of fields that uniquely identify each object in the results. For example, if a `name` field isn't unique, ordering by it won't guarantee objects with the same name always appear in the same order.

## `reverse()`

### `reverse()`

Use the `reverse()` method to reverse the order in which a queryset's elements are returned. Calling `reverse()` a second time restores the ordering back to the normal direction.

To retrieve the "last" five items in a queryset, you could do this:

```
my_queryset.reverse()[:5]
```

Note that this is not quite the same as slicing from the end of a sequence in Python. The above example will return the last item first, then the penultimate item and so on. If we had a Python sequence and looked at `seq[-5:]`, we would see the fifth-last item first. Django doesn't support that mode of access (slicing from the end), because it's not possible to do it efficiently in SQL.

Also, note that `reverse()` should generally only be called on a `QuerySet` which has a defined ordering (e.g., when querying against a model which defines a default ordering, or when using `order_by()`). If no such ordering is defined for a given `QuerySet`, calling `reverse()` on it has no real effect (the ordering was undefined prior to calling `reverse()`, and will remain undefined afterward).

## `distinct()`

### `distinct(*fields)`

Returns a new `QuerySet` that uses `SELECT DISTINCT` in its SQL query. This eliminates duplicate rows from the query results.

By default, a `QuerySet` will not eliminate duplicate rows. In practice, this is rarely a problem, because simple queries such as `Blog.objects.all()` don't introduce the possibility of duplicate result rows. However, if your query spans multiple tables, it's possible to get duplicate results when a `QuerySet` is evaluated. That's when you'd use `distinct()`.

---

**Note:** Any fields used in an `order_by()` call are included in the SQL `SELECT` columns. This can sometimes lead to unexpected results when used in conjunction with `distinct()`. If you order by fields from a related model, those fields will be added to the selected columns and they may make otherwise duplicate rows appear to be distinct. Since the extra columns don't appear in the returned results (they are only there to support ordering), it sometimes looks like non-distinct results are being returned.

Similarly, if you use a `values()` query to restrict the columns selected, the columns used in any `order_by()` (or default model ordering) will still be involved and may affect uniqueness of the results.

The moral here is that if you are using `distinct()` be careful about ordering by related models. Similarly, when using `distinct()` and `values()` together, be careful when ordering by fields not in the `values()` call.

---

On PostgreSQL only, you can pass positional arguments (`*fields`) in order to specify the names of fields to which the `DISTINCT` should apply. This translates to a `SELECT DISTINCT ON` SQL query. Here's the difference. For a normal `distinct()` call, the database compares *each* field in each row when determining which rows are distinct. For a `distinct()` call with specified field names, the database will only compare the specified field names.

---

**Note:** When you specify field names, you *must* provide an `order_by()` in the `QuerySet`, and the fields in `order_by()` must start with the fields in `distinct()`, in the same order.

For example, `SELECT DISTINCT ON (a)` gives you the first row for each value in column `a`. If you don't specify an order, you'll get some arbitrary row.

---

Examples (those after the first will only work on PostgreSQL):

```
>>> Author.objects.distinct()
[...]

>>> Entry.objects.order_by('pub_date').distinct('pub_date')
[...]

>>> Entry.objects.order_by('blog').distinct('blog')
[...]

>>> Entry.objects.order_by('author', 'pub_date').distinct('author', 'pub_date')
[...]

>>> Entry.objects.order_by('blog__name', 'mod_date').distinct('blog__name', 'mod_date
↪')
[...]

>>> Entry.objects.order_by('author', 'pub_date').distinct('author')
[...]
```

---

**Note:** Keep in mind that `order_by()` uses any default related model ordering that has been defined. You might have to explicitly order by the relation `_id` or referenced field to make sure the `DISTINCT ON` expressions match those at the beginning of the `ORDER BY` clause. For example, if the `Blog` model defined an `ordering` by name:

```
Entry.objects.order_by('blog').distinct('blog')
```

...wouldn't work because the query would be ordered by `blog__name` thus mismatching the `DISTINCT ON` expression. You'd have to explicitly order by the relation `_id` field (`blog_id` in this case) or the referenced one (`blog__pk`) to make sure both expressions match.

## values()

### values(\*fields)

Returns a `QuerySet` that returns dictionaries, rather than model instances, when used as an iterable.

Each of those dictionaries represents an object, with the keys corresponding to the attribute names of model objects.

This example compares the dictionaries of `values()` with the normal model objects:

```
# This list contains a Blog object.
>>> Blog.objects.filter(name__startswith='Beatles')
<QuerySet [<Blog: Beatles Blog>]>

# This list contains a dictionary.
>>> Blog.objects.filter(name__startswith='Beatles').values()
<QuerySet [{ 'id': 1, 'name': 'Beatles Blog', 'tagline': 'All the latest Beatles news.
↪' }]>
```

The `values()` method takes optional positional arguments, `*fields`, which specify field names to which the `SELECT` should be limited. If you specify the fields, each dictionary will contain only the field keys/values for the fields you specify. If you don't specify the fields, each dictionary will contain a key and value for every field in the database table.

Example:

```
>>> Blog.objects.values()
<QuerySet [{ 'id': 1, 'name': 'Beatles Blog', 'tagline': 'All the latest Beatles news.
↪' }]>
>>> Blog.objects.values('id', 'name')
<QuerySet [{ 'id': 1, 'name': 'Beatles Blog' }]>
```

A few subtleties that are worth mentioning:

- If you have a field called `foo` that is a *ForeignKey*, the default `values()` call will return a dictionary key called `foo_id`, since this is the name of the hidden model attribute that stores the actual value (the `foo` attribute refers to the related model). When you are calling `values()` and passing in field names, you can pass in either `foo` or `foo_id` and you will get back the same thing (the dictionary key will match the field name you passed in).

For example:

```
>>> Entry.objects.values()
<QuerySet [{ 'blog_id': 1, 'headline': 'First Entry', ... }, ...]>

>>> Entry.objects.values('blog')
<QuerySet [{ 'blog': 1 }, ...]>

>>> Entry.objects.values('blog_id')
<QuerySet [{ 'blog_id': 1 }, ...]>
```

- When using `values()` together with `distinct()`, be aware that ordering can affect the results. See the note in `distinct()` for details.
- If you use a `values()` clause after an `extra()` call, any fields defined by a `select` argument in the `extra()` must be explicitly included in the `values()` call. Any `extra()` call made after a `values()` call will have its extra selected fields ignored.
- Calling `only()` and `defer()` after `values()` doesn't make sense, so doing so will raise a `NotImplementedError`.

It is useful when you know you're only going to need values from a small number of the available fields and you won't need the functionality of a model instance object. It's more efficient to select only the fields you need to use.

Finally, note that you can call `filter()`, `order_by()`, etc. after the `values()` call, that means that these two calls are identical:

```
Blog.objects.values().order_by('id')
Blog.objects.order_by('id').values()
```

The people who made Django prefer to put all the SQL-affecting methods first, followed (optionally) by any output-affecting methods (such as `values()`), but it doesn't really matter. This is your chance to really flaunt your individualism.

You can also refer to fields on related models with reverse relations through `OneToOneField`, `ForeignKey` and `ManyToManyField` attributes:

```
>>> Blog.objects.values('name', 'entry__headline')
<QuerySet [{'name': 'My blog', 'entry__headline': 'An entry'},
           {'name': 'My blog', 'entry__headline': 'Another entry'}, ...]>
```

**Warning:** Because `ManyToManyField` attributes and reverse relations can have multiple related rows, including these can have a multiplier effect on the size of your result set. This will be especially pronounced if you include multiple such fields in your `values()` query, in which case all possible combinations will be returned.

## `values_list()`

`values_list(*fields, flat=False)`

This is similar to `values()` except that instead of returning dictionaries, it returns tuples when iterated over. Each tuple contains the value from the respective field passed into the `values_list()` call — so the first item is the first field, etc. For example:

```
>>> Entry.objects.values_list('id', 'headline')
[(1, 'First entry'), ...]
```

If you only pass in a single field, you can also pass in the `flat` parameter. If `True`, this will mean the returned results are single values, rather than one-tuples. An example should make the difference clearer:

```
>>> Entry.objects.values_list('id').order_by('id')
[(1,), (2,), (3,), ...]

>>> Entry.objects.values_list('id', flat=True).order_by('id')
[1, 2, 3, ...]
```

It is an error to pass in `flat` when there is more than one field.

If you don't pass any values to `values_list()`, it will return all the fields in the model, in the order they were declared.

A common need is to get a specific field value of a certain model instance. To achieve that, use `values_list()` followed by a `get()` call:

```
>>> Entry.objects.values_list('headline', flat=True).get(pk=1)
'First entry'
```

`values()` and `values_list()` are both intended as optimizations for a specific use case: retrieving a subset of data without the overhead of creating a model instance. This metaphor falls apart when dealing with many-to-many and other multivalued relations (such as the one-to-many relation of a reverse foreign key) because the “one row, one object” assumption doesn't hold.

For example, notice the behavior when querying across a `ManyToManyField`:

```
>>> Author.objects.values_list('name', 'entry__headline')
[('Noam Chomsky', 'Impressions of Gaza'),
 ('George Orwell', 'Why Socialists Do Not Believe in Fun'),
 ('George Orwell', 'In Defence of English Cooking'),
 ('Don Quixote', None)]
```

Authors with multiple entries appear multiple times and authors without any entries have `None` for the entry headline.

Similarly, when querying a reverse foreign key, `None` appears for entries not having any author:

```
>>> Entry.objects.values_list('authors')
[('Noam Chomsky',), ('George Orwell',), (None,)]
```

## dates()

**dates** (*field, kind, order='ASC'*)

Returns a `QuerySet` that evaluates to a list of `datetime.date` objects representing all available dates of a particular kind within the contents of the `QuerySet`.

`field` should be the name of a `DateField` of your model. `kind` should be either "year", "month" or "day". Each `datetime.date` object in the result list is “truncated” to the given type.

- "year" returns a list of all distinct year values for the field.
- "month" returns a list of all distinct year/month values for the field.
- "day" returns a list of all distinct year/month/day values for the field.

`order`, which defaults to 'ASC', should be either 'ASC' or 'DESC'. This specifies how to order the results.

Examples:

```
>>> Entry.objects.dates('pub_date', 'year')
[datetime.date(2005, 1, 1)]
>>> Entry.objects.dates('pub_date', 'month')
[datetime.date(2005, 2, 1), datetime.date(2005, 3, 1)]
>>> Entry.objects.dates('pub_date', 'day')
[datetime.date(2005, 3, 20), datetime.date(2005, 3, 20)]
>>> Entry.objects.dates('pub_date', 'day', order='DESC')
[datetime.date(2005, 3, 20), datetime.date(2005, 2, 20)]
>>> Entry.objects.filter(headline__contains='Lennon').dates('pub_date', 'day')
[datetime.date(2005, 3, 20)]
```

## `datetimes()`

**`datetimes`** (*field\_name*, *kind*, *order*='ASC', *tzinfo*=None)

Returns a `QuerySet` that evaluates to a list of `datetime.datetime` objects representing all available dates of a particular kind within the contents of the `QuerySet`.

`field_name` should be the name of a `DateTimeField` of your model.

`kind` should be either "year", "month", "day", "hour", "minute" or "second". Each `datetime.datetime` object in the result list is "truncated" to the given type.

`order`, which defaults to 'ASC', should be either 'ASC' or 'DESC'. This specifies how to order the results.

`tzinfo` defines the time zone to which datetimes are converted prior to truncation. Indeed, a given `datetime` has different representations depending on the time zone in use. This parameter must be a `datetime.tzinfo` object. If it's `None`, Django uses the *current time zone*. It has no effect when `USE_TZ` is `False`.

---

**Note:** This function performs time zone conversions directly in the database. As a consequence, your database must be able to interpret the value of `tzinfo.tzname` (`None`). This translates into the following requirements:

- SQLite: install `pytz` — conversions are actually performed in Python.
  - PostgreSQL: no requirements (see [Time Zones](#)).
  - Oracle: no requirements (see [Choosing a Time Zone File](#)).
  - MySQL: install `pytz` and load the time zone tables with `mysql_tzinfo_to_sql`.
- 

## `none()`

**`none`** ()

Calling `none()` will create a `queryset` that never returns any objects and no query will be executed when accessing the results. A `qs.none()` `queryset` is an instance of `EmptyQuerySet`.

Examples:

```
>>> Entry.objects.none()
<QuerySet []>
>>> from django.db.models.query import EmptyQuerySet
>>> isinstance(Entry.objects.none(), EmptyQuerySet)
True
```

## `all()`

**`all`** ()

Returns a *copy* of the current `QuerySet` (or `QuerySet` subclass). This can be useful in situations where you might want to pass in either a model manager or a `QuerySet` and do further filtering on the result. After calling `all()` on either object, you'll definitely have a `QuerySet` to work with.

When a `QuerySet` is *evaluated*, it typically caches its results. If the data in the database might have changed since a `QuerySet` was evaluated, you can get updated results for the same query by calling `all()` on a previously evaluated `QuerySet`.

**select\_related()****select\_related(\*fields)**

Returns a `QuerySet` that will “follow” foreign-key relationships, selecting additional related-object data when it executes its query. This is a performance booster which results in a single more complex query but means later use of foreign-key relationships won’t require database queries.

The following examples illustrate the difference between plain lookups and `select_related()` lookups. Here’s standard lookup:

```
# Hits the database.
e = Entry.objects.get(id=5)

# Hits the database again to get the related Blog object.
b = e.blog
```

And here’s `select_related` lookup:

```
# Hits the database.
e = Entry.objects.select_related('blog').get(id=5)

# Doesn't hit the database, because e.blog has been prepopulated
# in the previous query.
b = e.blog
```

You can use `select_related()` with any queryset of objects:

```
from django.utils import timezone

# Find all the blogs with entries scheduled to be published in the future.
blogs = set()

for e in Entry.objects.filter(pub_date__gt=timezone.now()).select_related('blog'):
    # Without select_related(), this would make a database query for each
    # loop iteration in order to fetch the related blog for each entry.
    blogs.add(e.blog)
```

The order of `filter()` and `select_related()` chaining isn’t important. These querysets are equivalent:

```
Entry.objects.filter(pub_date__gt=timezone.now()).select_related('blog')
Entry.objects.select_related('blog').filter(pub_date__gt=timezone.now())
```

You can follow foreign keys in a similar way to querying them. If you have the following models:

```
from django.db import models

class City(models.Model):
    # ...
    pass

class Person(models.Model):
    # ...
    hometown = models.ForeignKey(
        City,
        on_delete=models.SET_NULL,
        blank=True,
        null=True,
```

```
)  
  
class Book(models.Model):  
    # ...  
    author = models.ForeignKey(Person, on_delete=models.CASCADE)
```

... then a call to `Book.objects.select_related('author__hometown').get(id=4)` will cache the related `Person` *and* the related `City`:

```
b = Book.objects.select_related('author__hometown').get(id=4)  
p = b.author          # Doesn't hit the database.  
c = p.hometown        # Doesn't hit the database.  
  
b = Book.objects.get(id=4) # No select_related() in this example.  
p = b.author          # Hits the database.  
c = p.hometown        # Hits the database.
```

You can refer to any `ForeignKey` or `OneToOneField` relation in the list of fields passed to `select_related()`.

You can also refer to the reverse direction of a `OneToOneField` in the list of fields passed to `select_related` — that is, you can traverse a `OneToOneField` back to the object on which the field is defined. Instead of specifying the field name, use the `related_name` for the field on the related object.

There may be some situations where you wish to call `select_related()` with a lot of related objects, or where you don't know all of the relations. In these cases it is possible to call `select_related()` with no arguments. This will follow all non-null foreign keys it can find - nullable foreign keys must be specified. This is not recommended in most cases as it is likely to make the underlying query more complex, and return more data, than is actually needed.

If you need to clear the list of related fields added by past calls of `select_related` on a `QuerySet`, you can pass `None` as a parameter:

```
>>> without_relations = queryset.select_related(None)
```

Chaining `select_related` calls works in a similar way to other methods - that is that `select_related('foo', 'bar')` is equivalent to `select_related('foo').select_related('bar')`.

### **prefetch\_related()**

#### **prefetch\_related(\*lookups)**

Returns a `QuerySet` that will automatically retrieve, in a single batch, related objects for each of the specified lookups.

This has a similar purpose to `select_related`, in that both are designed to stop the deluge of database queries that is caused by accessing related objects, but the strategy is quite different.

`select_related` works by creating an SQL join and including the fields of the related object in the `SELECT` statement. For this reason, `select_related` gets the related objects in the same database query. However, to avoid the much larger result set that would result from joining across a 'many' relationship, `select_related` is limited to single-valued relationships - foreign key and one-to-one.

`prefetch_related`, on the other hand, does a separate lookup for each relationship, and does the 'joining' in Python. This allows it to prefetch many-to-many and many-to-one objects, which cannot be done using `select_related`, in addition to the foreign key and one-to-one relationships that are supported by

`select_related`. It also supports prefetching of *GenericRelation* and *GenericForeignKey*, however, it must be restricted to a homogeneous set of results. For example, prefetching objects referenced by a *GenericForeignKey* is only supported if the query is restricted to one *ContentType*.

For example, suppose you have these models:

```
from django.db import models

class Topping(models.Model):
    name = models.CharField(max_length=30)

class Pizza(models.Model):
    name = models.CharField(max_length=50)
    toppings = models.ManyToManyField(Topping)

    def __str__(self):
        # __unicode__ on Python 2
        return "%s (%s)" % (
            self.name,
            ", ".join(topping.name for topping in self.toppings.all()),
        )
```

and run:

```
>>> Pizza.objects.all()
["Hawaiian (ham, pineapple)", "Seafood (prawns, smoked salmon)"...
```

The problem with this is that every time `Pizza.__str__()` asks for `self.toppings.all()` it has to query the database, so `Pizza.objects.all()` will run a query on the `Toppings` table for **every** item in the `Pizza` `QuerySet`.

We can reduce to just two queries using `prefetch_related`:

```
>>> Pizza.objects.all().prefetch_related('toppings')
```

This implies a `self.toppings.all()` for each `Pizza`; now each time `self.toppings.all()` is called, instead of having to go to the database for the items, it will find them in a prefetched `QuerySet` cache that was populated in a single query.

That is, all the relevant toppings will have been fetched in a single query, and used to make `QuerySets` that have a pre-filled cache of the relevant results; these `QuerySets` are then used in the `self.toppings.all()` calls.

The additional queries in `prefetch_related()` are executed after the `QuerySet` has begun to be evaluated and the primary query has been executed.

If you have an iterable of model instances, you can prefetch related attributes on those instances using the `prefetch_related_objects()` function.

Note that the result cache of the primary `QuerySet` and all specified related objects will then be fully loaded into memory. This changes the typical behavior of `QuerySets`, which normally try to avoid loading all objects into memory before they are needed, even after a query has been executed in the database.

**Note:** Remember that, as always with `QuerySets`, any subsequent chained methods which imply a different database query will ignore previously cached results, and retrieve data using a fresh database query. So, if you write the following:

```
>>> pizzas = Pizza.objects.prefetch_related('toppings')
>>> [list(pizza.toppings.filter(spicy=True)) for pizza in pizzas]
```

...then the fact that `pizza.toppings.all()` has been prefetched will not help you. The `prefetch_related('toppings')` implied `pizza.toppings.all()`, but `pizza.toppings.filter()` is a new and different query. The prefetched cache can't help here; in fact it hurts performance, since you have done a database query that you haven't used. So use this feature with caution!

---

You can also use the normal join syntax to do related fields of related fields. Suppose we have an additional model to the example above:

```
class Restaurant(models.Model):
    pizzas = models.ManyToManyField(Pizza, related_name='restaurants')
    best_pizza = models.ForeignKey(Pizza, related_name='championed_by')
```

The following are all legal:

```
>>> Restaurant.objects.prefetch_related('pizzas__toppings')
```

This will prefetch all pizzas belonging to restaurants, and all toppings belonging to those pizzas. This will result in a total of 3 database queries - one for the restaurants, one for the pizzas, and one for the toppings.

```
>>> Restaurant.objects.prefetch_related('best_pizza__toppings')
```

This will fetch the best pizza and all the toppings for the best pizza for each restaurant. This will be done in 3 database queries - one for the restaurants, one for the 'best pizzas', and one for one for the toppings.

Of course, the `best_pizza` relationship could also be fetched using `select_related` to reduce the query count to 2:

```
>>> Restaurant.objects.select_related('best_pizza').prefetch_related('best_pizza__
↳toppings')
```

Since the prefetch is executed after the main query (which includes the joins needed by `select_related`), it is able to detect that the `best_pizza` objects have already been fetched, and it will skip fetching them again.

Chaining `prefetch_related` calls will accumulate the lookups that are prefetched. To clear any `prefetch_related` behavior, pass `None` as a parameter:

```
>>> non_prefetched = qs.prefetch_related(None)
```

One difference to note when using `prefetch_related` is that objects created by a query can be shared between the different objects that they are related to i.e. a single Python model instance can appear at more than one point in the tree of objects that are returned. This will normally happen with foreign key relationships. Typically this behavior will not be a problem, and will in fact save both memory and CPU time.

While `prefetch_related` supports prefetching `GenericForeignKey` relationships, the number of queries will depend on the data. Since a `GenericForeignKey` can reference data in multiple tables, one query per table referenced is needed, rather than one query for all the items. There could be additional queries on the `ContentType` table if the relevant rows have not already been fetched.

`prefetch_related` in most cases will be implemented using an SQL query that uses the 'IN' operator. This means that for a large `QuerySet` a large 'IN' clause could be generated, which, depending on the database, might have performance problems of its own when it comes to parsing or executing the SQL query. Always profile for your use case!

Note that if you use `iterator()` to run the query, `prefetch_related()` calls will be ignored since these two optimizations do not make sense together.

You can use the `Prefetch` object to further control the prefetch operation.

In its simplest form `Prefetch` is equivalent to the traditional string based lookups:

```
>>> from django.db.models import Prefetch
>>> Restaurant.objects.prefetch_related(Prefetch('pizzas__toppings'))
```

You can provide a custom queryset with the optional `queryset` argument. This can be used to change the default ordering of the queryset:

```
>>> Restaurant.objects.prefetch_related(
...     Prefetch('pizzas__toppings', queryset=Toppings.objects.order_by('name')))
```

Or to call `select_related()` when applicable to reduce the number of queries even further:

```
>>> Pizza.objects.prefetch_related(
...     Prefetch('restaurants', queryset=Restaurant.objects.select_related('best_pizza
...     ↪')))
```

You can also assign the prefetched result to a custom attribute with the optional `to_attr` argument. The result will be stored directly in a list.

This allows prefetching the same relation multiple times with a different `QuerySet`; for instance:

```
>>> vegetarian_pizzas = Pizza.objects.filter(vegetarian=True)
>>> Restaurant.objects.prefetch_related(
...     Prefetch('pizzas', to_attr='menu'),
...     Prefetch('pizzas', queryset=vegetarian_pizzas, to_attr='vegetarian_menu'))
```

Lookups created with custom `to_attr` can still be traversed as usual by other lookups:

```
>>> vegetarian_pizzas = Pizza.objects.filter(vegetarian=True)
>>> Restaurant.objects.prefetch_related(
...     Prefetch('pizzas', queryset=vegetarian_pizzas, to_attr='vegetarian_menu'),
...     'vegetarian_menu__toppings')
```

Using `to_attr` is recommended when filtering down the prefetch result as it is less ambiguous than storing a filtered result in the related manager's cache:

```
>>> queryset = Pizza.objects.filter(vegetarian=True)
>>>
>>> # Recommended:
>>> restaurants = Restaurant.objects.prefetch_related(
...     Prefetch('pizzas', queryset=queryset, to_attr='vegetarian_pizzas'))
>>> vegetarian_pizzas = restaurants[0].vegetarian_pizzas
>>>
>>> # Not recommended:
>>> restaurants = Restaurant.objects.prefetch_related(
...     Prefetch('pizzas', queryset=queryset))
>>> vegetarian_pizzas = restaurants[0].pizzas.all()
```

Custom prefetching also works with single related relations like forward `ForeignKey` or `OneToOneField`. Generally you'll want to use `select_related()` for these relations, but there are a number of cases where prefetching with a custom `QuerySet` is useful:

- You want to use a `QuerySet` that performs further prefetching on related models.
- You want to prefetch only a subset of the related objects.
- You want to use performance optimization techniques like *deferred fields*:

```
>>> queryset = Pizza.objects.only('name')
>>>
```

```
>>> restaurants = Restaurant.objects.prefetch_related(
...     Prefetch('best_pizza', queryset=queryset))
```

**Note:** The ordering of lookups matters.

Take the following examples:

```
>>> prefetch_related('pizzas__toppings', 'pizzas')
```

This works even though it's unordered because 'pizzas\_\_toppings' already contains all the needed information, therefore the second argument 'pizzas' is actually redundant.

```
>>> prefetch_related('pizzas__toppings', Prefetch('pizzas', queryset=Pizza.objects.
↳ all()))
```

This will raise a `ValueError` because of the attempt to redefine the queryset of a previously seen lookup. Note that an implicit queryset was created to traverse 'pizzas' as part of the 'pizzas\_\_toppings' lookup.

```
>>> prefetch_related('pizza_list__toppings', Prefetch('pizzas', to_attr='pizza_list'))
```

This will trigger an `AttributeError` because 'pizza\_list' doesn't exist yet when 'pizza\_list\_\_toppings' is being processed.

This consideration is not limited to the use of `Prefetch` objects. Some advanced techniques may require that the lookups be performed in a specific order to avoid creating extra queries; therefore it's recommended to always carefully order `prefetch_related` arguments.

---

## `extra()`

**extra** (*select=None, where=None, params=None, tables=None, order\_by=None, select\_params=None*)

Sometimes, the Django query syntax by itself can't easily express a complex `WHERE` clause. For these edge cases, Django provides the `extra()` `QuerySet` modifier — a hook for injecting specific clauses into the SQL generated by a `QuerySet`.

---

### Use this method as a last resort

This is an old API that we aim to deprecate at some point in the future. Use it only if you cannot express your query using other queryset methods. If you do need to use it, please [file a ticket](#) using the `QuerySet.extra` keyword with your use case (please check the list of existing tickets first) so that we can enhance the `QuerySet` API to allow removing `extra()`. We are no longer improving or fixing bugs for this method.

For example, this use of `extra()`:

```
>>> qs.extra(
...     select={'val': "select col from sometable where othercol = %s"},
...     select_params=(someparam, ),
... )
```

is equivalent to:

```
>>> qs.annotate(val=RawSQL("select col from sometable where othercol = %s",
↳ (someparam,)))
```

The main benefit of using *RawSQL* is that you can set `output_field` if needed. The main downside is that if you refer to some table alias of the queryset in the raw SQL, then it is possible that Django might change that alias (for example, when the queryset is used as a subquery in yet another query).

**Warning:** You should be very careful whenever you use `extra()`. Every time you use it, you should escape any parameters that the user can control by using `params` in order to protect against SQL injection attacks. Please read more about [SQL injection protection](#).

By definition, these extra lookups may not be portable to different database engines (because you're explicitly writing SQL code) and violate the DRY principle, so you should avoid them if possible.

Specify one or more of `params`, `select`, `where` or `tables`. None of the arguments is required, but you should use at least one of them.

- `select`

The `select` argument lets you put extra fields in the `SELECT` clause. It should be a dictionary mapping attribute names to SQL clauses to use to calculate that attribute.

Example:

```
Entry.objects.extra(select={'is_recent': "pub_date > '2006-01-01'"})
```

As a result, each `Entry` object will have an extra attribute, `is_recent`, a boolean representing whether the entry's `pub_date` is greater than Jan. 1, 2006.

Django inserts the given SQL snippet directly into the `SELECT` statement, so the resulting SQL of the above example would be something like:

```
SELECT blog_entry.*, (pub_date > '2006-01-01') AS is_recent
FROM blog_entry;
```

The next example is more advanced; it does a subquery to give each resulting `Blog` object an `entry_count` attribute, an integer count of associated `Entry` objects:

```
Blog.objects.extra(
    select={
        'entry_count': 'SELECT COUNT(*) FROM blog_entry WHERE blog_entry.blog_id_
↳= blog_blog.id'
    },
)
```

In this particular case, we're exploiting the fact that the query will already contain the `blog_blog` table in its `FROM` clause.

The resulting SQL of the above example would be:

```
SELECT blog_blog.*, (SELECT COUNT(*) FROM blog_entry WHERE blog_entry.blog_id =_
↳blog_blog.id) AS entry_count
FROM blog_blog;
```

Note that the parentheses required by most database engines around subqueries are not required in Django's `select` clauses. Also note that some database backends, such as some MySQL versions, don't support subqueries.

In some rare cases, you might wish to pass parameters to the SQL fragments in `extra(select=...)`. For this purpose, use the `select_params` parameter. Since `select_params` is a sequence and the `select`

attribute is a dictionary, some care is required so that the parameters are matched up correctly with the extra select pieces. In this situation, you should use a `collections.OrderedDict` for the `select` value, not just a normal Python dictionary.

This will work, for example:

```
Blog.objects.extra(  
    select=OrderedDict([('a', '%s'), ('b', '%s')]),  
    select_params=('one', 'two'))
```

If you need to use a literal `%s` inside your select string, use the sequence `%%s`.

- `where / tables`

You can define explicit SQL `WHERE` clauses — perhaps to perform non-explicit joins — by using `where`. You can manually add tables to the SQL `FROM` clause by using `tables`.

`where` and `tables` both take a list of strings. All `where` parameters are “AND”ed to any other search criteria.

Example:

```
Entry.objects.extra(where=["foo='a' OR bar = 'a'", "baz = 'a'"])
```

...translates (roughly) into the following SQL:

```
SELECT * FROM blog_entry WHERE (foo='a' OR bar='a') AND (baz='a')
```

Be careful when using the `tables` parameter if you’re specifying tables that are already used in the query. When you add extra tables via the `tables` parameter, Django assumes you want that table included an extra time, if it is already included. That creates a problem, since the table name will then be given an alias. If a table appears multiple times in an SQL statement, the second and subsequent occurrences must use aliases so the database can tell them apart. If you’re referring to the extra table you added in the extra `where` parameter this is going to cause errors.

Normally you’ll only be adding extra tables that don’t already appear in the query. However, if the case outlined above does occur, there are a few solutions. First, see if you can get by without including the extra table and use the one already in the query. If that isn’t possible, put your `extra()` call at the front of the queryset construction so that your table is the first use of that table. Finally, if all else fails, look at the query produced and rewrite your `where` addition to use the alias given to your extra table. The alias will be the same each time you construct the queryset in the same way, so you can rely upon the alias name to not change.

- `order_by`

If you need to order the resulting queryset using some of the new fields or tables you have included via `extra()` use the `order_by` parameter to `extra()` and pass in a sequence of strings. These strings should either be model fields (as in the normal `order_by()` method on querysets), of the form `table_name.column_name` or an alias for a column that you specified in the `select` parameter to `extra()`.

For example:

```
q = Entry.objects.extra(select={'is_recent': "pub_date > '2006-01-01'"})  
q = q.extra(order_by = ['-is_recent'])
```

This would sort all the items for which `is_recent` is true to the front of the result set (True sorts before False in a descending ordering).

This shows, by the way, that you can make multiple calls to `extra()` and it will behave as you expect (adding new constraints each time).

- `params`

The `where` parameter described above may use standard Python database string placeholders — `'%s'` to indicate parameters the database engine should automatically quote. The `params` argument is a list of any extra parameters to be substituted.

Example:

```
Entry.objects.extra(where=['headline=%s'], params=['Lennon'])
```

Always use `params` instead of embedding values directly into `where` because `params` will ensure values are quoted correctly according to your particular backend. For example, quotes will be escaped correctly.

Bad:

```
Entry.objects.extra(where=["headline='Lennon'"])
```

Good:

```
Entry.objects.extra(where=['headline=%s'], params=['Lennon'])
```

**Warning:** If you are performing queries on MySQL, note that MySQL's silent type coercion may cause unexpected results when mixing types. If you query on a string type column, but with an integer value, MySQL will coerce the types of all values in the table to an integer before performing the comparison. For example, if your table contains the values `'abc'`, `'def'` and you query for `WHERE mycolumn=0`, both rows will match. To prevent this, perform the correct typecasting before using the value in a query.

## defer()

### defer(\*fields)

In some complex data-modeling situations, your models might contain a lot of fields, some of which could contain a lot of data (for example, text fields), or require expensive processing to convert them to Python objects. If you are using the results of a queryset in some situation where you don't know if you need those particular fields when you initially fetch the data, you can tell Django not to retrieve them from the database.

This is done by passing the names of the fields to not load to `defer()`:

```
Entry.objects.defer("headline", "body")
```

A queryset that has deferred fields will still return model instances. Each deferred field will be retrieved from the database if you access that field (one at a time, not all the deferred fields at once).

You can make multiple calls to `defer()`. Each call adds new fields to the deferred set:

```
# Defers both the body and headline fields.
Entry.objects.defer("body").filter(rating=5).defer("headline")
```

The order in which fields are added to the deferred set does not matter. Calling `defer()` with a field name that has already been deferred is harmless (the field will still be deferred).

You can defer loading of fields in related models (if the related models are loading via `select_related()`) by using the standard double-underscore notation to separate related fields:

```
Blog.objects.select_related().defer("entry__headline", "entry__body")
```

If you want to clear the set of deferred fields, pass `None` as a parameter to `defer()`:

```
# Load all fields immediately.
my_queryset.defer(None)
```

Some fields in a model won't be deferred, even if you ask for them. You can never defer the loading of the primary key. If you are using `select_related()` to retrieve related models, you shouldn't defer the loading of the field that connects from the primary model to the related one, doing so will result in an error.

---

**Note:** The `defer()` method (and its cousin, `only()`, below) are only for advanced use-cases. They provide an optimization for when you have analyzed your queries closely and understand *exactly* what information you need and have measured that the difference between returning the fields you need and the full set of fields for the model will be significant.

Even if you think you are in the advanced use-case situation, **only use `defer()` when you cannot, at queryset load time, determine if you will need the extra fields or not.** If you are frequently loading and using a particular subset of your data, the best choice you can make is to normalize your models and put the non-loaded data into a separate model (and database table). If the columns *must* stay in the one table for some reason, create a model with `Meta.managed = False` (see the *managed attribute* documentation) containing just the fields you normally need to load and use that where you might otherwise call `defer()`. This makes your code more explicit to the reader, is slightly faster and consumes a little less memory in the Python process.

For example, both of these models use the same underlying database table:

```
class CommonlyUsedModel(models.Model):
    f1 = models.CharField(max_length=10)

    class Meta:
        managed = False
        db_table = 'app_targetable'

class ManagedModel(models.Model):
    f1 = models.CharField(max_length=10)
    f2 = models.CharField(max_length=10)

    class Meta:
        db_table = 'app_targetable'

# Two equivalent QuerySets:
CommonlyUsedModel.objects.all()
ManagedModel.objects.all().defer('f2')
```

If many fields need to be duplicated in the unmanaged model, it may be best to create an abstract model with the shared fields and then have the unmanaged and managed models inherit from the abstract model.

---

**Note:** When calling `save()` for instances with deferred fields, only the loaded fields will be saved. See `save()` for more details.

---

## `only()`

### `only(*fields)`

The `only()` method is more or less the opposite of `defer()`. You call it with the fields that should *not* be deferred when retrieving a model. If you have a model where almost all the fields need to be deferred, using `only()` to specify the complementary set of fields can result in simpler code.

Suppose you have a model with fields `name`, `age` and `biography`. The following two queriesets are the same, in terms of deferred fields:

```
Person.objects.defer("age", "biography")
Person.objects.only("name")
```

Whenever you call `only()` it *replaces* the set of fields to load immediately. The method's name is mnemonic: **only** those fields are loaded immediately; the remainder are deferred. Thus, successive calls to `only()` result in only the final fields being considered:

```
# This will defer all fields except the headline.
Entry.objects.only("body", "rating").only("headline")
```

Since `defer()` acts incrementally (adding fields to the deferred list), you can combine calls to `only()` and `defer()` and things will behave logically:

```
# Final result is that everything except "headline" is deferred.
Entry.objects.only("headline", "body").defer("body")

# Final result loads headline and body immediately (only() replaces any
# existing set of fields).
Entry.objects.defer("body").only("headline", "body")
```

All of the cautions in the note for the `defer()` documentation apply to `only()` as well. Use it cautiously and only after exhausting your other options.

Using `only()` and omitting a field requested using `select_related()` is an error as well.

---

**Note:** When calling `save()` for instances with deferred fields, only the loaded fields will be saved. See `save()` for more details.

---

## `using()`

### `using (alias)`

This method is for controlling which database the `QuerySet` will be evaluated against if you are using more than one database. The only argument this method takes is the alias of a database, as defined in `DATABASES`.

For example:

```
# queries the database with the 'default' alias.
>>> Entry.objects.all()

# queries the database with the 'backup' alias
>>> Entry.objects.using('backup')
```

## `select_for_update()`

### `select_for_update (nowait=False)`

Returns a queryset that will lock rows until the end of the transaction, generating a `SELECT ... FOR UPDATE` SQL statement on supported databases.

For example:

```
entries = Entry.objects.select_for_update().filter(author=request.user)
```

All matched entries will be locked until the end of the transaction block, meaning that other transactions will be prevented from changing or acquiring locks on them.

Usually, if another transaction has already acquired a lock on one of the selected rows, the query will block until the lock is released. If this is not the behavior you want, call `select_for_update(nowait=True)`. This will make the call non-blocking. If a conflicting lock is already acquired by another transaction, `DatabaseError` will be raised when the queryset is evaluated.

Currently, the `postgresql`, `oracle`, and `mysql` database backends support `select_for_update()`. However, MySQL has no support for the `nowait` argument. Obviously, users of external third-party backends should check with their backend's documentation for specifics in those cases.

Passing `nowait=True` to `select_for_update()` using database backends that do not support `nowait`, such as MySQL, will cause a `DatabaseError` to be raised. This is in order to prevent code unexpectedly blocking.

Evaluating a queryset with `select_for_update()` in autocommit mode on backends which support `SELECT ... FOR UPDATE` is a `TransactionManagementError` error because the rows are not locked in that case. If allowed, this would facilitate data corruption and could easily be caused by calling code that expects to be run in a transaction outside of one.

Using `select_for_update()` on backends which do not support `SELECT ... FOR UPDATE` (such as SQLite) will have no effect. `SELECT ... FOR UPDATE` will not be added to the query, and an error isn't raised if `select_for_update()` is used in autocommit mode.

**Warning:** Although `select_for_update()` normally fails in autocommit mode, since `TestCase` automatically wraps each test in a transaction, calling `select_for_update()` in a `TestCase` even outside an `atomic()` block will (perhaps unexpectedly) pass without raising a `TransactionManagementError`. To properly test `select_for_update()` you should use `TransactionTestCase`.

## `raw()`

`raw(raw_query, params=None, translations=None)`

Takes a raw SQL query, executes it, and returns a `django.db.models.query.RawQuerySet` instance. This `RawQuerySet` instance can be iterated over just like a normal `QuerySet` to provide object instances.

See the [Performing raw SQL queries](#) for more information.

**Warning:** `raw()` always triggers a new query and doesn't account for previous filtering. As such, it should generally be called from the `Manager` or from a fresh `QuerySet` instance.

## Methods that do not return QuerySets

The following `QuerySet` methods evaluate the `QuerySet` and return something *other than* a `QuerySet`.

These methods do not use a cache (see [Caching and QuerySets](#)). Rather, they query the database each time they're called.

## get ()

### get (\*\*kwargs)

Returns the object matching the given lookup parameters, which should be in the format described in *Field lookups*.

`get ()` raises `MultipleObjectsReturned` if more than one object was found. The `MultipleObjectsReturned` exception is an attribute of the model class.

`get ()` raises a `DoesNotExist` exception if an object wasn't found for the given parameters. This exception is an attribute of the model class. Example:

```
Entry.objects.get(id='foo') # raises Entry.DoesNotExist
```

The `DoesNotExist` exception inherits from `django.core.exceptions.ObjectDoesNotExist`, so you can target multiple `DoesNotExist` exceptions. Example:

```
from django.core.exceptions import ObjectDoesNotExist
try:
    e = Entry.objects.get(id=3)
    b = Blog.objects.get(id=1)
except ObjectDoesNotExist:
    print("Either the entry or blog doesn't exist.")
```

If you expect a queryset to return one row, you can use `get ()` without any arguments to return the object for that row:

```
entry = Entry.objects.filter(...).exclude(...).get ()
```

## create ()

### create (\*\*kwargs)

A convenience method for creating an object and saving it all in one step. Thus:

```
p = Person.objects.create(first_name="Bruce", last_name="Springsteen")
```

and:

```
p = Person(first_name="Bruce", last_name="Springsteen")
p.save(force_insert=True)
```

are equivalent.

The `force_insert` parameter is documented elsewhere, but all it means is that a new object will always be created. Normally you won't need to worry about this. However, if your model contains a manual primary key value that you set and if that value already exists in the database, a call to `create ()` will fail with an `IntegrityError` since primary keys must be unique. Be prepared to handle the exception if you are using manual primary keys.

## get\_or\_create ()

### get\_or\_create (defaults=None, \*\*kwargs)

A convenience method for looking up an object with the given `kwargs` (may be empty if your model has defaults for all fields), creating one if necessary.

Returns a tuple of (object, created), where `object` is the retrieved or created object and `created` is a boolean specifying whether a new object was created.

This is meant as a shortcut to boilerplatish code. For example:

```
try:
    obj = Person.objects.get(first_name='John', last_name='Lennon')
except Person.DoesNotExist:
    obj = Person(first_name='John', last_name='Lennon', birthday=date(1940, 10, 9))
    obj.save()
```

This pattern gets quite unwieldy as the number of fields in a model goes up. The above example can be rewritten using `get_or_create()` like so:

```
obj, created = Person.objects.get_or_create(
    first_name='John',
    last_name='Lennon',
    defaults={'birthday': date(1940, 10, 9)},
)
```

Any keyword arguments passed to `get_or_create()` — *except* an optional one called `defaults` — will be used in a `get()` call. If an object is found, `get_or_create()` returns a tuple of that object and `False`. If multiple objects are found, `get_or_create` raises `MultipleObjectsReturned`. If an object is *not* found, `get_or_create()` will instantiate and save a new object, returning a tuple of the new object and `True`. The new object will be created roughly according to this algorithm:

```
params = {k: v for k, v in kwargs.items() if '__' not in k}
params.update(defaults)
obj = self.model(**params)
obj.save()
```

In English, that means start with any non-`'defaults'` keyword argument that doesn't contain a double underscore (which would indicate a non-exact lookup). Then add the contents of `defaults`, overriding any keys if necessary, and use the result as the keyword arguments to the model class. As hinted at above, this is a simplification of the algorithm that is used, but it contains all the pertinent details. The internal implementation has some more error-checking than this and handles some extra edge-conditions; if you're interested, read the code.

If you have a field named `defaults` and want to use it as an exact lookup in `get_or_create()`, just use `'defaults__exact'`, like so:

```
Foo.objects.get_or_create(defaults__exact='bar', defaults={'defaults': 'baz'})
```

The `get_or_create()` method has similar error behavior to `create()` when you're using manually specified primary keys. If an object needs to be created and the key already exists in the database, an `IntegrityError` will be raised.

This method is atomic assuming correct usage, correct database configuration, and correct behavior of the underlying database. However, if uniqueness is not enforced at the database level for the `kwargs` used in a `get_or_create` call (see `unique` or `unique_together`), this method is prone to a race-condition which can result in multiple rows with the same parameters being inserted simultaneously.

If you are using MySQL, be sure to use the `READ COMMITTED` isolation level rather than `REPEATABLE READ` (the default), otherwise you may see cases where `get_or_create` will raise an `IntegrityError` but the object won't appear in a subsequent `get()` call.

Finally, a word on using `get_or_create()` in Django views. Please make sure to use it only in POST requests unless you have a good reason not to. GET requests shouldn't have any effect on data. Instead, use POST whenever a request to a page has a side effect on your data. For more, see [Safe methods](#) in the HTTP spec.

**Warning:** You can use `get_or_create()` through *ManyToManyField* attributes and reverse relations. In that case you will restrict the queries inside the context of that relation. That could lead you to some integrity problems if you don't use it consistently.

Being the following models:

```
class Chapter(models.Model):
    title = models.CharField(max_length=255, unique=True)

class Book(models.Model):
    title = models.CharField(max_length=256)
    chapters = models.ManyToManyField(Chapter)
```

You can use `get_or_create()` through `Book`'s `chapters` field, but it only fetches inside the context of that book:

```
>>> book = Book.objects.create(title="Ulysses")
>>> book.chapters.get_or_create(title="Telemachus")
(<Chapter: Telemachus>, True)
>>> book.chapters.get_or_create(title="Telemachus")
(<Chapter: Telemachus>, False)
>>> Chapter.objects.create(title="Chapter 1")
<Chapter: Chapter 1>
>>> book.chapters.get_or_create(title="Chapter 1")
# Raises IntegrityError
```

This is happening because it's trying to get or create "Chapter 1" through the book "Ulysses", but it can't do any of them: the relation can't fetch that chapter because it isn't related to that book, but it can't create it either because `title` field should be unique.

## `update_or_create()`

`update_or_create` (*defaults=None, \*\*kwargs*)

A convenience method for updating an object with the given `kwargs`, creating a new one if necessary. The `defaults` is a dictionary of (field, value) pairs used to update the object.

Returns a tuple of (object, created), where `object` is the created or updated object and `created` is a boolean specifying whether a new object was created.

The `update_or_create` method tries to fetch an object from database based on the given `kwargs`. If a match is found, it updates the fields passed in the `defaults` dictionary.

This is meant as a shortcut to boilerplatish code. For example:

```
defaults = {'first_name': 'Bob'}
try:
    obj = Person.objects.get(first_name='John', last_name='Lennon')
    for key, value in defaults.items():
        setattr(obj, key, value)
    obj.save()
except Person.DoesNotExist:
    new_values = {'first_name': 'John', 'last_name': 'Lennon'}
    new_values.update(defaults)
    obj = Person(**new_values)
    obj.save()
```

This pattern gets quite unwieldy as the number of fields in a model goes up. The above example can be rewritten using `update_or_create()` like so:

```
obj, created = Person.objects.update_or_create(
    first_name='John', last_name='Lennon',
    defaults={'first_name': 'Bob'},
)
```

For detailed description how names passed in `kwargs` are resolved see `get_or_create()`.

As described above in `get_or_create()`, this method is prone to a race-condition which can result in multiple rows being inserted simultaneously if uniqueness is not enforced at the database level.

### `bulk_create()`

**`bulk_create`** (*objs*, *batch\_size=None*)

This method inserts the provided list of objects into the database in an efficient manner (generally only 1 query, no matter how many objects there are):

```
>>> Entry.objects.bulk_create([
...     Entry(headline='This is a test'),
...     Entry(headline='This is only a test'),
... ])
```

This has a number of caveats though:

- The model's `save()` method will not be called, and the `pre_save` and `post_save` signals will not be sent.
- It does not work with child models in a multi-table inheritance scenario.
- If the model's primary key is an `AutoField` it does not retrieve and set the primary key attribute, as `save()` does, unless the database backend supports it (currently PostgreSQL).
- It does not work with many-to-many relationships.

Support for using `bulk_create()` with proxy models was added.

Support for setting primary keys on objects created using `bulk_create()` when using PostgreSQL was added.

The `batch_size` parameter controls how many objects are created in single query. The default is to create all objects in one batch, except for SQLite where the default is such that at most 999 variables per query are used.

### `count()`

**`count`** ()

Returns an integer representing the number of objects in the database matching the `QuerySet`. The `count()` method never raises exceptions.

Example:

```
# Returns the total number of entries in the database.
Entry.objects.count()

# Returns the number of entries whose headline contains 'Lennon'
Entry.objects.filter(headline__contains='Lennon').count()
```

A `count()` call performs a `SELECT COUNT(*)` behind the scenes, so you should always use `count()` rather than loading all of the record into Python objects and calling `len()` on the result (unless you need to load the objects into memory anyway, in which case `len()` will be faster).

Depending on which database you're using (e.g. PostgreSQL vs. MySQL), `count()` may return a long integer instead of a normal Python integer. This is an underlying implementation quirk that shouldn't pose any real-world problems.

Note that if you want the number of items in a `QuerySet` and are also retrieving model instances from it (for example, by iterating over it), it's probably more efficient to use `len(queryset)` which won't cause an extra database query like `count()` would.

### `in_bulk()`

#### `in_bulk(id_list=None)`

Takes a list of primary-key values and returns a dictionary mapping each primary-key value to an instance of the object with the given ID. If a list isn't provided, all objects in the `queryset` are returned.

Example:

```
>>> Blog.objects.in_bulk([1])
{1: <Blog: Beatles Blog>}
>>> Blog.objects.in_bulk([1, 2])
{1: <Blog: Beatles Blog>, 2: <Blog: Cheddar Talk>}
>>> Blog.objects.in_bulk([])
{}
>>> Blog.objects.in_bulk()
{1: <Blog: Beatles Blog>, 2: <Blog: Cheddar Talk>, 3: <Blog: Django Weblog>}
```

If you pass `in_bulk()` an empty list, you'll get an empty dictionary.

In older versions, `id_list` was a required argument.

### `iterator()`

#### `iterator()`

Evaluates the `QuerySet` (by performing the query) and returns an iterator (see [PEP 234](#)) over the results. A `QuerySet` typically caches its results internally so that repeated evaluations do not result in additional queries. In contrast, `iterator()` will read results directly, without doing any caching at the `QuerySet` level (internally, the default iterator calls `iterator()` and caches the return value). For a `QuerySet` which returns a large number of objects that you only need to access once, this can result in better performance and a significant reduction in memory.

Note that using `iterator()` on a `QuerySet` which has already been evaluated will force it to evaluate again, repeating the query.

Also, use of `iterator()` causes previous `prefetch_related()` calls to be ignored since these two optimizations do not make sense together.

**Warning:** Some Python database drivers like `psycopg2` perform caching if using client side cursors (instantiated with `connection.cursor()` and what Django's ORM uses). Using `iterator()` does not affect caching at the database driver level. To disable this caching, look at [server side cursors](#).

## latest ()

**latest** (*field\_name=None*)

Returns the latest object in the table, by date, using the `field_name` provided as the date field.

This example returns the latest `Entry` in the table, according to the `pub_date` field:

```
Entry.objects.latest('pub_date')
```

If your model's *Meta* specifies `get_latest_by`, you can leave off the `field_name` argument to `earliest()` or `latest()`. Django will use the field specified in `get_latest_by` by default.

Like `get()`, `earliest()` and `latest()` raise `DoesNotExist` if there is no object with the given parameters.

Note that `earliest()` and `latest()` exist purely for convenience and readability.

---

### earliest () and latest () may return instances with null dates.

Since ordering is delegated to the database, results on fields that allow null values may be ordered differently if you use different databases. For example, PostgreSQL and MySQL sort null values as if they are higher than non-null values, while SQLite does the opposite.

You may want to filter out null values:

```
Entry.objects.filter(pub_date__isnull=False).latest('pub_date')
```

## earliest ()

**earliest** (*field\_name=None*)

Works otherwise like `latest()` except the direction is changed.

## first ()

**first** ()

Returns the first object matched by the queryset, or `None` if there is no matching object. If the `QuerySet` has no ordering defined, then the queryset is automatically ordered by the primary key.

Example:

```
p = Article.objects.order_by('title', 'pub_date').first()
```

Note that `first()` is a convenience method, the following code sample is equivalent to the above example:

```
try:
    p = Article.objects.order_by('title', 'pub_date')[0]
except IndexError:
    p = None
```

## last ()

**last** ()

Works like `first()`, but returns the last object in the queryset.

## `aggregate()`

`aggregate(*args, **kwargs)`

Returns a dictionary of aggregate values (averages, sums, etc.) calculated over the `QuerySet`. Each argument to `aggregate()` specifies a value that will be included in the dictionary that is returned.

The aggregation functions that are provided by Django are described in [Aggregation Functions](#) below. Since aggregates are also *query expressions*, you may combine aggregates with other aggregates or values to create complex aggregates.

Aggregates specified using keyword arguments will use the keyword as the name for the annotation. Anonymous arguments will have a name generated for them based upon the name of the aggregate function and the model field that is being aggregated. Complex aggregates cannot use anonymous arguments and must specify a keyword argument as an alias.

For example, when you are working with blog entries, you may want to know the number of authors that have contributed blog entries:

```
>>> from django.db.models import Count
>>> q = Blog.objects.aggregate(Count('entry'))
{'entry__count': 16}
```

By using a keyword argument to specify the aggregate function, you can control the name of the aggregation value that is returned:

```
>>> q = Blog.objects.aggregate(number_of_entries=Count('entry'))
{'number_of_entries': 16}
```

For an in-depth discussion of aggregation, see [the topic guide on Aggregation](#).

## `exists()`

`exists()`

Returns `True` if the `QuerySet` contains any results, and `False` if not. This tries to perform the query in the simplest and fastest way possible, but it *does* execute nearly the same query as a normal `QuerySet` query.

`exists()` is useful for searches relating to both object membership in a `QuerySet` and to the existence of any objects in a `QuerySet`, particularly in the context of a large `QuerySet`.

The most efficient method of finding whether a model with a unique field (e.g. `primary_key`) is a member of a `QuerySet` is:

```
entry = Entry.objects.get(pk=123)
if some_queryset.filter(pk=entry.pk).exists():
    print("Entry contained in queryset")
```

Which will be faster than the following which requires evaluating and iterating through the entire queryset:

```
if entry in some_queryset:
    print("Entry contained in QuerySet")
```

And to find whether a queryset contains any items:

```
if some_queryset.exists():
    print("There is at least one object in some_queryset")
```

Which will be faster than:

```
if some_queryset:
    print("There is at least one object in some_queryset")
```

... but not by a large degree (hence needing a large queryset for efficiency gains).

Additionally, if a `some_queryset` has not yet been evaluated, but you know that it will be at some point, then using `some_queryset.exists()` will do more overall work (one query for the existence check plus an extra one to later retrieve the results) than simply using `bool(some_queryset)`, which retrieves the results and then checks if any were returned.

## update()

**update(\*\*kwargs)**

Performs an SQL update query for the specified fields, and returns the number of rows matched (which may not be equal to the number of rows updated if some rows already have the new value).

For example, to turn comments off for all blog entries published in 2010, you could do this:

```
>>> Entry.objects.filter(pub_date__year=2010).update(comments_on=False)
```

(This assumes your `Entry` model has fields `pub_date` and `comments_on`.)

You can update multiple fields — there's no limit on how many. For example, here we update the `comments_on` and `headline` fields:

```
>>> Entry.objects.filter(pub_date__year=2010).update(comments_on=False, headline=
↪'This is old')
```

The `update()` method is applied instantly, and the only restriction on the `QuerySet` that is updated is that it can only update columns in the model's main table, not on related models. You can't do this, for example:

```
>>> Entry.objects.update(blog__name='foo') # Won't work!
```

Filtering based on related fields is still possible, though:

```
>>> Entry.objects.filter(blog__id=1).update(comments_on=True)
```

You cannot call `update()` on a `QuerySet` that has had a slice taken or can otherwise no longer be filtered.

The `update()` method returns the number of affected rows:

```
>>> Entry.objects.filter(id=64).update(comments_on=True)
1
>>> Entry.objects.filter(slug='nonexistent-slug').update(comments_on=True)
0
>>> Entry.objects.filter(pub_date__year=2010).update(comments_on=False)
132
```

If you're just updating a record and don't need to do anything with the model object, the most efficient approach is to call `update()`, rather than loading the model object into memory. For example, instead of doing this:

```
e = Entry.objects.get(id=10)
e.comments_on = False
e.save()
```

...do this:

```
Entry.objects.filter(id=10).update(comments_on=False)
```

Using `update()` also prevents a race condition wherein something might change in your database in the short period of time between loading the object and calling `save()`.

Finally, realize that `update()` does an update at the SQL level and, thus, does not call any `save()` methods on your models, nor does it emit the `pre_save` or `post_save` signals (which are a consequence of calling `Model.save()`). If you want to update a bunch of records for a model that has a custom `save()` method, loop over them and call `save()`, like this:

```
for e in Entry.objects.filter(pub_date__year=2010):
    e.comments_on = False
    e.save()
```

## `delete()`

### `delete()`

Performs an SQL delete query on all rows in the *QuerySet* and returns the number of objects deleted and a dictionary with the number of deletions per object type.

The `delete()` is applied instantly. You cannot call `delete()` on a *QuerySet* that has had a slice taken or can otherwise no longer be filtered.

For example, to delete all the entries in a particular blog:

```
>>> b = Blog.objects.get(pk=1)

# Delete all the entries belonging to this Blog.
>>> Entry.objects.filter(blog=b).delete()
(4, {'weblog.Entry': 2, 'weblog.Entry_authors': 2})
```

The return value describing the number of objects deleted was added.

By default, Django's *ForeignKey* emulates the SQL constraint `ON DELETE CASCADE` — in other words, any objects with foreign keys pointing at the objects to be deleted will be deleted along with them. For example:

```
>>> blogs = Blog.objects.all()

# This will delete all Blogs and all of their Entry objects.
>>> blogs.delete()
(5, {'weblog.Blog': 1, 'weblog.Entry': 2, 'weblog.Entry_authors': 2})
```

This cascade behavior is customizable via the `on_delete` argument to the *ForeignKey*.

The `delete()` method does a bulk delete and does not call any `delete()` methods on your models. It does, however, emit the `pre_delete` and `post_delete` signals for all deleted objects (including cascaded deletions).

Django needs to fetch objects into memory to send signals and handle cascades. However, if there are no cascades and no signals, then Django may take a fast-path and delete objects without fetching into memory. For large deletes this can result in significantly reduced memory usage. The amount of executed queries can be reduced, too.

ForeignKeys which are set to `on_delete=DO_NOTHING` do not prevent taking the fast-path in deletion.

Note that the queries generated in object deletion is an implementation detail subject to change.

### `as_manager()`

### `classmethod as_manager()`

Class method that returns an instance of *Manager* with a copy of the *QuerySet*'s methods. See *Creating a manager with QuerySet methods* for more details.

## Field lookups

Field lookups are how you specify the meat of an SQL *WHERE* clause. They're specified as keyword arguments to the *QuerySet* methods `filter()`, `exclude()` and `get()`.

For an introduction, see *models and database queries documentation*.

Django's built-in lookups are listed below. It is also possible to write *custom lookups* for model fields.

As a convenience when no lookup type is provided (like in `Entry.objects.get(id=14)`) the lookup type is assumed to be *exact*.

### **exact**

Exact match. If the value provided for comparison is `None`, it will be interpreted as an SQL *NULL* (see *isnull* for more details).

Examples:

```
Entry.objects.get(id__exact=14)
Entry.objects.get(id__exact=None)
```

SQL equivalents:

```
SELECT ... WHERE id = 14;
SELECT ... WHERE id IS NULL;
```

---

## MySQL comparisons

In MySQL, a database table's "collation" setting determines whether *exact* comparisons are case-sensitive. This is a database setting, *not* a Django setting. It's possible to configure your MySQL tables to use case-sensitive comparisons, but some trade-offs are involved. For more information about this, see the *collation section* in the *databases documentation*.

---

### **ixact**

Case-insensitive exact match. If the value provided for comparison is `None`, it will be interpreted as an SQL *NULL* (see *isnull* for more details).

Example:

```
Blog.objects.get(name__iexact='beatles blog')
Blog.objects.get(name__iexact=None)
```

SQL equivalents:

```
SELECT ... WHERE name ILIKE 'beatles blog';
SELECT ... WHERE name IS NULL;
```

Note the first query will match 'Beatles Blog', 'beatles blog', 'BeAtLes BLoG', etc.

---

### SQLite users

When using the SQLite backend and Unicode (non-ASCII) strings, bear in mind the *database note* about string comparisons. SQLite does not do case-insensitive matching for Unicode strings.

---

### contains

Case-sensitive containment test.

Example:

```
Entry.objects.get(headline__contains='Lennon')
```

SQL equivalent:

```
SELECT ... WHERE headline LIKE '%Lennon%';
```

Note this will match the headline 'Lennon honored today' but not 'lennon honored today'.

---

### SQLite users

SQLite doesn't support case-sensitive LIKE statements; contains acts like icontains for SQLite. See the *database note* for more information.

---

### icontains

Case-insensitive containment test.

Example:

```
Entry.objects.get(headline__icontains='Lennon')
```

SQL equivalent:

```
SELECT ... WHERE headline ILIKE '%Lennon%';
```

### SQLite users

When using the SQLite backend and Unicode (non-ASCII) strings, bear in mind the *database note* about string comparisons.

---

## in

In a given list.

Example:

```
Entry.objects.filter(id__in=[1, 3, 4])
```

SQL equivalent:

```
SELECT ... WHERE id IN (1, 3, 4);
```

You can also use a queryset to dynamically evaluate the list of values instead of providing a list of literal values:

```
inner_qs = Blog.objects.filter(name__contains='Cheddar')
entries = Entry.objects.filter(blog__in=inner_qs)
```

This queryset will be evaluated as subselect statement:

```
SELECT ... WHERE blog.id IN (SELECT id FROM ... WHERE NAME LIKE '%Cheddar%')
```

If you pass in a `QuerySet` resulting from `values()` or `values_list()` as the value to an `__in` lookup, you need to ensure you are only extracting one field in the result. For example, this will work (filtering on the blog names):

```
inner_qs = Blog.objects.filter(name__contains='Ch').values('name')
entries = Entry.objects.filter(blog__name__in=inner_qs)
```

This example will raise an exception, since the inner query is trying to extract two field values, where only one is expected:

```
# Bad code! Will raise a TypeError.
inner_qs = Blog.objects.filter(name__contains='Ch').values('name', 'id')
entries = Entry.objects.filter(blog__name__in=inner_qs)
```

---

## Performance considerations

Be cautious about using nested queries and understand your database server's performance characteristics (if in doubt, benchmark!). Some database backends, most notably MySQL, don't optimize nested queries very well. It is more efficient, in those cases, to extract a list of values and then pass that into the second query. That is, execute two queries instead of one:

```
values = Blog.objects.filter(
    name__contains='Cheddar').values_list('pk', flat=True)
entries = Entry.objects.filter(blog__in=list(values))
```

Note the `list()` call around the `Blog QuerySet` to force execution of the first query. Without it, a nested query would be executed, because *QuerySets are lazy*.

---

## gt

Greater than.

Example:

```
Entry.objects.filter(id__gt=4)
```

SQL equivalent:

```
SELECT ... WHERE id > 4;
```

### **gte**

Greater than or equal to.

### **lt**

Less than.

### **lte**

Less than or equal to.

### **startswith**

Case-sensitive starts-with.

Example:

```
Entry.objects.filter(headline__startswith='Will')
```

SQL equivalent:

```
SELECT ... WHERE headline LIKE 'Will%';
```

SQLite doesn't support case-sensitive LIKE statements; `startswith` acts like `istartswith` for SQLite.

### **istartswith**

Case-insensitive starts-with.

Example:

```
Entry.objects.filter(headline__istartswith='will')
```

SQL equivalent:

```
SELECT ... WHERE headline ILIKE 'Will%';
```

---

## **SQLite users**

When using the SQLite backend and Unicode (non-ASCII) strings, bear in mind the *database note* about string comparisons.

---

### **endswith**

Case-sensitive ends-with.

Example:

```
Entry.objects.filter(headline__endswith='cats')
```

SQL equivalent:

```
SELECT ... WHERE headline LIKE '%cats';
```

---

### **SQLite users**

SQLite doesn't support case-sensitive LIKE statements; `endswith` acts like `iendswith` for SQLite. Refer to the [database note](#) documentation for more.

---

### **iendswith**

Case-insensitive ends-with.

Example:

```
Entry.objects.filter(headline__iendswith='will')
```

SQL equivalent:

```
SELECT ... WHERE headline ILIKE '%will'
```

---

### **SQLite users**

When using the SQLite backend and Unicode (non-ASCII) strings, bear in mind the [database note](#) about string comparisons.

---

### **range**

Range test (inclusive).

Example:

```
import datetime
start_date = datetime.date(2005, 1, 1)
end_date = datetime.date(2005, 3, 31)
Entry.objects.filter(pub_date__range=(start_date, end_date))
```

SQL equivalent:

```
SELECT ... WHERE pub_date BETWEEN '2005-01-01' and '2005-03-31';
```

You can use `range` anywhere you can use `BETWEEN` in SQL — for dates, numbers and even characters.

**Warning:** Filtering a `DateTimeField` with dates won't include items on the last day, because the bounds are interpreted as "0am on the given date". If `pub_date` was a `DateTimeField`, the above expression would be turned into this SQL:

```
SELECT ... WHERE pub_date BETWEEN '2005-01-01 00:00:00' and '2005-03-31 00:00:00';
```

Generally speaking, you can't mix dates and datetimes.

## date

For datetime fields, casts the value as date. Allows chaining additional field lookups. Takes a date value.

Example:

```
Entry.objects.filter(pub_date__date=datetime.date(2005, 1, 1))
Entry.objects.filter(pub_date__date__gt=datetime.date(2005, 1, 1))
```

(No equivalent SQL code fragment is included for this lookup because implementation of the relevant query varies among different database engines.)

When `USE_TZ` is `True`, fields are converted to the current time zone before filtering.

## year

For date and datetime fields, an exact year match. Allows chaining additional field lookups. Takes an integer year.

Example:

```
Entry.objects.filter(pub_date__year=2005)
Entry.objects.filter(pub_date__year__gte=2005)
```

SQL equivalent:

```
SELECT ... WHERE pub_date BETWEEN '2005-01-01' AND '2005-12-31';
SELECT ... WHERE pub_date >= '2005-01-01';
```

(The exact SQL syntax varies for each database engine.)

When `USE_TZ` is `True`, datetime fields are converted to the current time zone before filtering.

Allowed chaining additional field lookups.

## month

For date and datetime fields, an exact month match. Allows chaining additional field lookups. Takes an integer 1 (January) through 12 (December).

Example:

```
Entry.objects.filter(pub_date__month=12)
Entry.objects.filter(pub_date__month__gte=6)
```

SQL equivalent:

```
SELECT ... WHERE EXTRACT('month' FROM pub_date) = '12';
SELECT ... WHERE EXTRACT('month' FROM pub_date) >= '6';
```

(The exact SQL syntax varies for each database engine.)

When `USE_TZ` is `True`, datetime fields are converted to the current time zone before filtering. This requires *time zone definitions in the database*.

Allowed chaining additional field lookups.

### day

For date and datetime fields, an exact day match. Allows chaining additional field lookups. Takes an integer day.

Example:

```
Entry.objects.filter(pub_date__day=3)
Entry.objects.filter(pub_date__day__gte=3)
```

SQL equivalent:

```
SELECT ... WHERE EXTRACT('day' FROM pub_date) = '3';
SELECT ... WHERE EXTRACT('day' FROM pub_date) >= '3';
```

(The exact SQL syntax varies for each database engine.)

Note this will match any record with a `pub_date` on the third day of the month, such as January 3, July 3, etc.

When `USE_TZ` is `True`, datetime fields are converted to the current time zone before filtering. This requires *time zone definitions in the database*.

Allowed chaining additional field lookups.

### week\_day

For date and datetime fields, a ‘day of the week’ match. Allows chaining additional field lookups.

Takes an integer value representing the day of week from 1 (Sunday) to 7 (Saturday).

Example:

```
Entry.objects.filter(pub_date__week_day=2)
Entry.objects.filter(pub_date__week_day__gte=2)
```

(No equivalent SQL code fragment is included for this lookup because implementation of the relevant query varies among different database engines.)

Note this will match any record with a `pub_date` that falls on a Monday (day 2 of the week), regardless of the month or year in which it occurs. Week days are indexed with day 1 being Sunday and day 7 being Saturday.

When `USE_TZ` is `True`, datetime fields are converted to the current time zone before filtering. This requires *time zone definitions in the database*.

Allowed chaining additional field lookups.

**hour**

For datetime and time fields, an exact hour match. Allows chaining additional field lookups. Takes an integer between 0 and 23.

Example:

```
Event.objects.filter(timestamp__hour=23)
Event.objects.filter(time__hour=5)
Event.objects.filter(timestamp__hour__gte=12)
```

SQL equivalent:

```
SELECT ... WHERE EXTRACT('hour' FROM timestamp) = '23';
SELECT ... WHERE EXTRACT('hour' FROM time) = '5';
SELECT ... WHERE EXTRACT('hour' FROM timestamp) >= '12';
```

(The exact SQL syntax varies for each database engine.)

For datetime fields, when `USE_TZ` is `True`, values are converted to the current time zone before filtering.

Added support for `TimeField` on SQLite (other databases supported it as of 1.7).

Allowed chaining additional field lookups.

**minute**

For datetime and time fields, an exact minute match. Allows chaining additional field lookups. Takes an integer between 0 and 59.

Example:

```
Event.objects.filter(timestamp__minute=29)
Event.objects.filter(time__minute=46)
Event.objects.filter(timestamp__minute__gte=29)
```

SQL equivalent:

```
SELECT ... WHERE EXTRACT('minute' FROM timestamp) = '29';
SELECT ... WHERE EXTRACT('minute' FROM time) = '46';
SELECT ... WHERE EXTRACT('minute' FROM timestamp) >= '29';
```

(The exact SQL syntax varies for each database engine.)

For datetime fields, When `USE_TZ` is `True`, values are converted to the current time zone before filtering.

Added support for `TimeField` on SQLite (other databases supported it as of 1.7).

Allowed chaining additional field lookups.

**second**

For datetime and time fields, an exact second match. Allows chaining additional field lookups. Takes an integer between 0 and 59.

Example:

```
Event.objects.filter(timestamp__second=31)
Event.objects.filter(time__second=2)
Event.objects.filter(timestamp__second__gte=31)
```

SQL equivalent:

```
SELECT ... WHERE EXTRACT('second' FROM timestamp) = '31';
SELECT ... WHERE EXTRACT('second' FROM time) = '2';
SELECT ... WHERE EXTRACT('second' FROM timestamp) >= '31';
```

(The exact SQL syntax varies for each database engine.)

For datetime fields, when `USE_TZ` is `True`, values are converted to the current time zone before filtering.

Added support for `TimeField` on SQLite (other databases supported it as of 1.7).

Allowed chaining additional field lookups.

### **isnull**

Takes either `True` or `False`, which correspond to SQL queries of `IS NULL` and `IS NOT NULL`, respectively.

Example:

```
Entry.objects.filter(pub_date__isnull=True)
```

SQL equivalent:

```
SELECT ... WHERE pub_date IS NULL;
```

### **search**

Deprecated since version 1.10: See [the 1.10 release notes](#) for how to replace it.

A boolean full-text search, taking advantage of full-text indexing. This is like `contains` but is significantly faster due to full-text indexing.

Example:

```
Entry.objects.filter(headline__search="+Django -jazz Python")
```

SQL equivalent:

```
SELECT ... WHERE MATCH(tablename, headline) AGAINST (+Django -jazz Python IN BOOLEAN_
↪MODE);
```

Note this is only available in MySQL and requires direct manipulation of the database to add the full-text index. By default Django uses `BOOLEAN MODE` for full text searches. See the [MySQL documentation](#) for additional details.

### **regex**

Case-sensitive regular expression match.

The regular expression syntax is that of the database backend in use. In the case of SQLite, which has no built in regular expression support, this feature is provided by a (Python) user-defined `REGEXP` function, and the regular expression syntax is therefore that of Python's `re` module.

Example:

```
Entry.objects.get(title__regex=r'^(An?|The) +')
```

SQL equivalents:

```
SELECT ... WHERE title REGEXP BINARY '^(An?|The) +'; -- MySQL
SELECT ... WHERE REGEXP_LIKE(title, '^(An?|The) +', 'c'); -- Oracle
SELECT ... WHERE title ~ '^(An?|The) +'; -- PostgreSQL
SELECT ... WHERE title REGEXP '^(An?|The) +'; -- SQLite
```

Using raw strings (e.g., `r'foo'` instead of `'foo'`) for passing in the regular expression syntax is recommended.

### **iregex**

Case-insensitive regular expression match.

Example:

```
Entry.objects.get(title__iregex=r'^(an?|the) +')
```

SQL equivalents:

```
SELECT ... WHERE title REGEXP '^(an?|the) +'; -- MySQL
SELECT ... WHERE REGEXP_LIKE(title, '^(an?|the) +', 'i'); -- Oracle
SELECT ... WHERE title ~* '^(an?|the) +'; -- PostgreSQL
SELECT ... WHERE title REGEXP '(?i)^(an?|the) +'; -- SQLite
```

## **Aggregation functions**

Django provides the following aggregation functions in the `django.db.models` module. For details on how to use these aggregate functions, see [the topic guide on aggregation](#). See the *Aggregate* documentation to learn how to create your aggregates.

**Warning:** SQLite can't handle aggregation on date/time fields out of the box. This is because there are no native date/time fields in SQLite and Django currently emulates these features using a text field. Attempts to use aggregation on date/time fields in SQLite will raise `NotImplementedError`.

### **Note**

Aggregation functions return `None` when used with an empty `QuerySet`. For example, the `Sum` aggregation function returns `None` instead of `0` if the `QuerySet` contains no entries. An exception is `Count`, which does return `0` if the `QuerySet` is empty.

All aggregates have the following parameters in common:

### **expression**

A string that references a field on the model, or a *query expression*.

### **output\_field**

An optional argument that represents the *model field* of the return value

---

**Note:** When combining multiple field types, Django can only determine the `output_field` if all fields are of the same type. Otherwise, you must provide the `output_field` yourself.

---

### **\*\*extra**

Keyword arguments that can provide extra context for the SQL generated by the aggregate.

### **Avg**

**class Avg** (*expression*, *output\_field=FloatField()*, *\*\*extra*)

Returns the mean value of the given expression, which must be numeric unless you specify a different `output_field`.

- Default alias: `<field>__avg`
- Return type: `float` (or the type of whatever `output_field` is specified)

The `output_field` parameter was added to allow aggregating over non-numeric columns, such as `DurationField`.

### **Count**

**class Count** (*expression*, *distinct=False*, *\*\*extra*)

Returns the number of objects that are related through the provided expression.

- Default alias: `<field>__count`
- Return type: `int`

Has one optional argument:

#### **distinct**

If `distinct=True`, the count will only include unique instances. This is the SQL equivalent of `COUNT(DISTINCT <field>)`. The default value is `False`.

### **Max**

**class Max** (*expression*, *output\_field=None*, *\*\*extra*)

Returns the maximum value of the given expression.

- Default alias: `<field>__max`
- Return type: same as input field, or `output_field` if supplied

## Min

**class** `Min` (*expression*, *output\_field=None*, *\*\*extra*)

Returns the minimum value of the given expression.

- Default alias: `<field>__min`
- Return type: same as input field, or `output_field` if supplied

## StdDev

**class** `StdDev` (*expression*, *sample=False*, *\*\*extra*)

Returns the standard deviation of the data in the provided expression.

- Default alias: `<field>__stddev`
- Return type: `float`

Has one optional argument:

### **sample**

By default, `StdDev` returns the population standard deviation. However, if `sample=True`, the return value will be the sample standard deviation.

---

## SQLite

SQLite doesn't provide `StdDev` out of the box. An implementation is available as an extension module for SQLite. Consult the [SQLite documentation](#) for instructions on obtaining and installing this extension.

---

## Sum

**class** `Sum` (*expression*, *output\_field=None*, *\*\*extra*)

Computes the sum of all values of the given expression.

- Default alias: `<field>__sum`
- Return type: same as input field, or `output_field` if supplied

## Variance

**class** `Variance` (*expression*, *sample=False*, *\*\*extra*)

Returns the variance of the data in the provided expression.

- Default alias: `<field>__variance`
- Return type: `float`

Has one optional argument:

### **sample**

By default, `Variance` returns the population variance. However, if `sample=True`, the return value will be the sample variance.

---

## SQLite

SQLite doesn't provide `Variance` out of the box. An implementation is available as an extension module for SQLite. Consult the [SQLite documentation](#) for instructions on obtaining and installing this extension.

---

## Query-related tools

This section provides reference material for query-related tools not documented elsewhere.

### Q() objects

#### class Q

A `Q()` object, like an `F` object, encapsulates a SQL expression in a Python object that can be used in database-related operations.

In general, `Q()` objects make it possible to define and reuse conditions. This permits the *construction of complex database queries* using `|` (OR) and `&` (AND) operators; in particular, it is not otherwise possible to use OR in `QuerySets`.

### Prefetch() objects

#### class Prefetch (lookup, queryset=None, to\_attr=None)

The `Prefetch()` object can be used to control the operation of `prefetch_related()`.

The `lookup` argument describes the relations to follow and works the same as the string based lookups passed to `prefetch_related()`. For example:

```
>>> from django.db.models import Prefetch
>>> Question.objects.prefetch_related(Prefetch('choice_set')).get().choice_set.all()
<QuerySet [<Choice: Not much>, <Choice: The sky>, <Choice: Just hacking again>]>
# This will only execute two queries regardless of the number of Question
# and Choice objects.
>>> Question.objects.prefetch_related(Prefetch('choice_set')).all()
<QuerySet [<Question: Question object>]>
```

The `queryset` argument supplies a base `QuerySet` for the given lookup. This is useful to further filter down the prefetch operation, or to call `select_related()` from the prefetched relation, hence reducing the number of queries even further:

```
>>> voted_choices = Choice.objects.filter(votes__gt=0)
>>> voted_choices
<QuerySet [<Choice: The sky>]>
>>> prefetch = Prefetch('choice_set', queryset=voted_choices)
>>> Question.objects.prefetch_related(prefetch).get().choice_set.all()
<QuerySet [<Choice: The sky>]>
```

The `to_attr` argument sets the result of the prefetch operation to a custom attribute:

```
>>> prefetch = Prefetch('choice_set', queryset=voted_choices, to_attr='voted_choices')
>>> Question.objects.prefetch_related(prefetch).get().voted_choices
<QuerySet [<Choice: The sky>]>
>>> Question.objects.prefetch_related(prefetch).get().choice_set.all()
<QuerySet [<Choice: Not much>, <Choice: The sky>, <Choice: Just hacking again>]>
```

---

**Note:** When using `to_attr` the prefetched result is stored in a list. This can provide a significant speed improvement over traditional `prefetch_related` calls which store the cached result within a `QuerySet` instance.

---

### `prefetch_related_objects()`

**`prefetch_related_objects`** (*model\_instances, \*related\_lookups*)

Prefetches the given lookups on an iterable of model instances. This is useful in code that receives a list of model instances as opposed to a `QuerySet`; for example, when fetching models from a cache or instantiating them manually.

Pass an iterable of model instances (must all be of the same class) and the lookups or *Prefetch* objects you want to prefetch for. For example:

```
>>> from django.db.models import prefetch_related_objects
>>> restaurants = fetch_top_restaurants_from_cache() # A list of Restaurants
>>> prefetch_related_objects(restaurants, 'pizzas__toppings')
```

## 6.15.9 Lookup API reference

This document has the API references of lookups, the Django API for building the `WHERE` clause of a database query. To learn how to *use* lookups, see *Making queries*; to learn how to *create* new lookups, see *Custom Lookups*.

The lookup API has two components: a *RegisterLookupMixin* class that registers lookups, and the *Query Expression API*, a set of methods that a class has to implement to be registrable as a lookup.

Django has two base classes that follow the query expression API and from where all Django builtin lookups are derived:

- *Lookup*: to lookup a field (e.g. the exact of `field_name__exact`)
- *Transform*: to transform a field

A lookup expression consists of three parts:

- Fields part (e.g. `Book.objects.filter(author__best_friends__first_name...)`);
- Transforms part (may be omitted) (e.g. `__lower__first3chars__reversed`);
- A lookup (e.g. `__icontains`) that, if omitted, defaults to `__exact`.

### Registration API

Django uses *RegisterLookupMixin* to give a class the interface to register lookups on itself. The two prominent examples are *Field*, the base class of all model fields, and *Aggregate*, the base class of all Django aggregates.

**class** `lookups.RegisterLookupMixin`

A mixin that implements the lookup API on a class.

**classmethod** `register_lookup` (*lookup, lookup\_name=None*)

Registers a new lookup in the class. For example `DateField.register_lookup(YearExact)` will register `YearExact` lookup on `DateField`. It overrides a lookup that already exists with the same name. `lookup_name` will be used for this lookup if provided, otherwise `lookup.lookup_name` will be used.

The `lookup_name` parameter was added.

**get\_lookup** (*lookup\_name*)

Returns the *Lookup* named `lookup_name` registered in the class. The default implementation looks recursively on all parent classes and checks if any has a registered lookup named `lookup_name`, returning the first match.

**get\_transform** (*transform\_name*)

Returns a *Transform* named `transform_name`. The default implementation looks recursively on all parent classes to check if any has the registered transform named `transform_name`, returning the first match.

For a class to be a lookup, it must follow the *Query Expression API*. *Lookup* and *Transform* naturally follow this API.

## The Query Expression API

The query expression API is a common set of methods that classes define to be usable in query expressions to translate themselves into SQL expressions. Direct field references, aggregates, and *Transform* are examples that follow this API. A class is said to follow the query expression API when it implements the following methods:

**as\_sql** (*self, compiler, connection*)

Responsible for producing the query string and parameters for the expression. The `compiler` is an *SQLCompiler* object, which has a `compile()` method that can be used to compile other expressions. The `connection` is the connection used to execute the query.

Calling `expression.as_sql()` is usually incorrect - instead `compiler.compile(expression)` should be used. The `compiler.compile()` method will take care of calling vendor-specific methods of the expression.

Custom keyword arguments may be defined on this method if it's likely that `as_vendorname()` methods or subclasses will need to supply data to override the generation of the SQL string. See *Func.as\_sql()* for example usage.

**as\_vendorname** (*self, compiler, connection*)

Works like `as_sql()` method. When an expression is compiled by `compiler.compile()`, Django will first try to call `as_vendorname()`, where `vendorname` is the vendor name of the backend used for executing the query. The `vendorname` is one of `postgresql`, `oracle`, `sqlite`, or `mysql` for Django's built-in backends.

**get\_lookup** (*lookup\_name*)

Must return the lookup named `lookup_name`. For instance, by returning `self.output_field.get_lookup(lookup_name)`.

**get\_transform** (*transform\_name*)

Must return the lookup named `transform_name`. For instance, by returning `self.output_field.get_transform(transform_name)`.

**output\_field**

Defines the type of class returned by the `get_lookup()` method. It must be a *Field* instance.

## Transform reference

**class Transform**

A *Transform* is a generic class to implement field transformations. A prominent example is `__year` that transforms a *DateField* into a *IntegerField*.

The notation to use a *Transform* in an lookup expression is `<expression>__<transformation>` (e.g. `date__year`).

This class follows the *Query Expression API*, which implies that you can use `<expression>__<transform1>__<transform2>`. It's a specialized *Func() expression* that only accepts one argument. It can also be used on the right hand side of a filter or directly as an annotation.

Transform is now a subclass of Func.

#### **bilateral**

A boolean indicating whether this transformation should apply to both `lhs` and `rhs`. Bilateral transformations will be applied to `rhs` in the same order as they appear in the lookup expression. By default it is set to `False`. For example usage, see *Custom Lookups*.

#### **lhs**

The left-hand side - what is being transformed. It must follow the *Query Expression API*.

#### **lookup\_name**

The name of the lookup, used for identifying it on parsing query expressions. It cannot contain the string `"__"`.

#### **output\_field**

Defines the class this transformation outputs. It must be a *Field* instance. By default is the same as its `lhs.output_field`.

## Lookup reference

### class Lookup

A `Lookup` is a generic class to implement lookups. A lookup is a query expression with a left-hand side, *lhs*; a right-hand side, *rhs*; and a `lookup_name` that is used to produce a boolean comparison between `lhs` and `rhs` such as `lhs in rhs` or `lhs > rhs`.

The notation to use a lookup in an expression is `<lhs>__<lookup_name>=<rhs>`.

This class doesn't follow the *Query Expression API* since it has `=<rhs>` on its construction: lookups are always the end of a lookup expression.

#### **lhs**

The left-hand side - what is being looked up. The object must follow the *Query Expression API*.

#### **rhs**

The right-hand side - what `lhs` is being compared against. It can be a plain value, or something that compiles into SQL, typically an `F()` object or a `QuerySet`.

#### **lookup\_name**

The name of this lookup, used to identify it on parsing query expressions. It cannot contain the string `"__"`.

#### **process\_lhs** (*compiler, connection, lhs=None*)

Returns a tuple `(lhs_string, lhs_params)`, as returned by `compiler.compile(lhs)`. This method can be overridden to tune how the `lhs` is processed.

`compiler` is an `SQLCompiler` object, to be used like `compiler.compile(lhs)` for compiling `lhs`. The `connection` can be used for compiling vendor specific SQL. If `lhs` is not `None`, use it as the processed `lhs` instead of `self.lhs`.

#### **process\_rhs** (*compiler, connection*)

Behaves the same way as `process_lhs()`, for the right-hand side.

## 6.15.10 Query Expressions

Query expressions describe a value or a computation that can be used as part of an update, create, filter, order by, annotation, or aggregate. There are a number of built-in expressions (documented below) that can be used to help you write queries. Expressions can be combined, or in some cases nested, to form more complex computations.

Support for using expressions when creating new model instances was added.

### Supported arithmetic

Django supports addition, subtraction, multiplication, division, modulo arithmetic, and the power operator on query expressions, using Python constants, variables, and even other expressions.

### Some examples

```
from django.db.models import F, Count, Value
from django.db.models.functions import Length, Upper

# Find companies that have more employees than chairs.
Company.objects.filter(num_employees__gt=F('num_chairs'))

# Find companies that have at least twice as many employees
# as chairs. Both the querysets below are equivalent.
Company.objects.filter(num_employees__gt=F('num_chairs') * 2)
Company.objects.filter(
    num_employees__gt=F('num_chairs') + F('num_chairs'))

# How many chairs are needed for each company to seat all employees?
>>> company = Company.objects.filter(
...     num_employees__gt=F('num_chairs')).annotate(
...     chairs_needed=F('num_employees') - F('num_chairs')).first()
>>> company.num_employees
120
>>> company.num_chairs
50
>>> company.chairs_needed
70

# Create a new company using expressions.
>>> company = Company.objects.create(name='Google', ticker=Upper(Value('goog')))
# Be sure to refresh it if you need to access the field.
>>> company.refresh_from_db()
>>> company.ticker
'GOOG'

# Annotate models with an aggregated value. Both forms
# below are equivalent.
Company.objects.annotate(num_products=Count('products'))
Company.objects.annotate(num_products=Count(F('products')))

# Aggregates can contain complex computations also
Company.objects.annotate(num_offerings=Count(F('products') + F('services'))))

# Expressions can also be used in order_by()
Company.objects.order_by(Length('name').asc())
Company.objects.order_by(Length('name').desc())
```

## Built-in Expressions

**Note:** These expressions are defined in `django.db.models.expressions` and `django.db.models.aggregates`, but for convenience they're available and usually imported from `django.db.models`.

### F () expressions

#### class F

An `F ()` object represents the value of a model field or annotated column. It makes it possible to refer to model field values and perform database operations using them without actually having to pull them out of the database into Python memory.

Instead, Django uses the `F ()` object to generate an SQL expression that describes the required operation at the database level.

This is easiest to understand through an example. Normally, one might do something like this:

```
# Tintin filed a news story!
reporter = Reporters.objects.get(name='Tintin')
reporter.stories_filed += 1
reporter.save()
```

Here, we have pulled the value of `reporter.stories_filed` from the database into memory and manipulated it using familiar Python operators, and then saved the object back to the database. But instead we could also have done:

```
from django.db.models import F

reporter = Reporters.objects.get(name='Tintin')
reporter.stories_filed = F('stories_filed') + 1
reporter.save()
```

Although `reporter.stories_filed = F('stories_filed') + 1` looks like a normal Python assignment of value to an instance attribute, in fact it's an SQL construct describing an operation on the database.

When Django encounters an instance of `F ()`, it overrides the standard Python operators to create an encapsulated SQL expression; in this case, one which instructs the database to increment the database field represented by `reporter.stories_filed`.

Whatever value is or was on `reporter.stories_filed`, Python never gets to know about it - it is dealt with entirely by the database. All Python does, through Django's `F ()` class, is create the SQL syntax to refer to the field and describe the operation.

To access the new value saved this way, the object must be reloaded:

```
reporter = Reporters.objects.get(pk=reporter.pk)
# Or, more succinctly:
reporter.refresh_from_db()
```

As well as being used in operations on single instances as above, `F ()` can be used on QuerySets of object instances, with `update ()`. This reduces the two queries we were using above - the `get ()` and the `save ()` - to just one:

```
reporter = Reporters.objects.filter(name='Tintin')
reporter.update(stories_filed=F('stories_filed') + 1)
```

We can also use `update()` to increment the field value on multiple objects - which could be very much faster than pulling them all into Python from the database, looping over them, incrementing the field value of each one, and saving each one back to the database:

```
Reporter.objects.all().update(stories_filed=F('stories_filed') + 1)
```

`F()` therefore can offer performance advantages by:

- getting the database, rather than Python, to do work
- reducing the number of queries some operations require

### Avoiding race conditions using `F()`

Another useful benefit of `F()` is that having the database - rather than Python - update a field's value avoids a *race condition*.

If two Python threads execute the code in the first example above, one thread could retrieve, increment, and save a field's value after the other has retrieved it from the database. The value that the second thread saves will be based on the original value; the work of the first thread will simply be lost.

If the database is responsible for updating the field, the process is more robust: it will only ever update the field based on the value of the field in the database when the `save()` or `update()` is executed, rather than based on its value when the instance was retrieved.

### `F()` assignments persist after `Model.save()`

`F()` objects assigned to model fields persist after saving the model instance and will be applied on each `save()`. For example:

```
reporter = Reporters.objects.get(name='Tintin')
reporter.stories_filed = F('stories_filed') + 1
reporter.save()

reporter.name = 'Tintin Jr.'
reporter.save()
```

`stories_filed` will be updated twice in this case. If it's initially 1, the final value will be 3.

### Using `F()` in filters

`F()` is also very useful in `QuerySet` filters, where they make it possible to filter a set of objects against criteria based on their field values, rather than on Python values.

This is documented in *using `F()` expressions in queries*.

### Using `F()` with annotations

`F()` can be used to create dynamic fields on your models by combining different fields with arithmetic:

```
company = Company.objects.annotate(
    chairs_needed=F('num_employees') - F('num_chairs'))
```

If the fields that you're combining are of different types you'll need to tell Django what kind of field will be returned. Since `F()` does not directly support `output_field` you will need to wrap the expression with `ExpressionWrapper`:

```
from django.db.models import DateTimeField, ExpressionWrapper, F

Ticket.objects.annotate(
    expires=ExpressionWrapper(
        F('active_at') + F('duration'), output_field=DateTimeField())
```

When referencing relational fields such as `ForeignKey`, `F()` returns the primary key value rather than a model instance:

```
>> car = Company.objects.annotate(built_by=F('manufacturer'))[0]
>> car.manufacturer
<Manufacturer: Toyota>
>> car.built_by
3
```

### Func() expressions

`Func()` expressions are the base type of all expressions that involve database functions like `COALESCE` and `LOWER`, or aggregates like `SUM`. They can be used directly:

```
from django.db.models import Func, F

queryset.annotate(field_lower=Func(F('field'), function='LOWER'))
```

or they can be used to build a library of database functions:

```
class Lower(Func):
    function = 'LOWER'

queryset.annotate(field_lower=Lower('field'))
```

But both cases will result in a queryset where each model is annotated with an extra attribute `field_lower` produced, roughly, from the following SQL:

```
SELECT
    ...
    LOWER("db_table"."field") as "field_lower"
```

See [Database Functions](#) for a list of built-in database functions.

The `Func` API is as follows:

```
class Func(*expressions, **extra)
```

#### function

A class attribute describing the function that will be generated. Specifically, the function will be interpolated as the `function` placeholder within `template`. Defaults to `None`.

#### template

A class attribute, as a format string, that describes the SQL that is generated for this function. Defaults to `'%(function)s(%(expressions)s)'`.

If you're constructing SQL like `strftime('%W', 'date')` and need a literal `%` character in the query, quadruple it (`%%%`) in the `template` attribute because the string is interpolated twice: once during the template interpolation in `as_sql()` and once in the SQL interpolation with the query parameters in the database cursor.

**arg\_joiner**

A class attribute that denotes the character used to join the list of expressions together. Defaults to `' , '`.

**arity**

A class attribute that denotes the number of arguments the function accepts. If this attribute is set and the function is called with a different number of expressions, `TypeError` will be raised. Defaults to `None`.

**as\_sql** (*compiler, connection, function=None, template=None, arg\_joiner=None, \*\*extra\_context*)

Generates the SQL for the database function.

The `as_vendor()` methods should use the `function`, `template`, `arg_joiner`, and any other `**extra_context` parameters to customize the SQL as needed. For example:

```
django/db/models/functions.py
```

```
class ConcatPair(Func):
    ...
    function = 'CONCAT'
    ...

    def as_mysql(self, compiler, connection):
        return super(ConcatPair, self).as_sql(
            compiler, connection,
            function='CONCAT_WS',
            template="%(function)s(' , %(expressions)s)",
        )
```

Support for the `arg_joiner` and `**extra_context` parameters was added.

The `*expressions` argument is a list of positional expressions that the function will be applied to. The expressions will be converted to strings, joined together with `arg_joiner`, and then interpolated into the `template` as the `expressions` placeholder.

Positional arguments can be expressions or Python values. Strings are assumed to be column references and will be wrapped in `F()` expressions while other values will be wrapped in `Value()` expressions.

The `**extra` kwargs are key=value pairs that can be interpolated into the `template` attribute. The `function`, `template`, and `arg_joiner` keywords can be used to replace the attributes of the same name without having to define your own class. `output_field` can be used to define the expected return type.

## Aggregate() expressions

An aggregate expression is a special case of a *Func() expression* that informs the query that a `GROUP BY` clause is required. All of the *aggregate functions*, like `Sum()` and `Count()`, inherit from `Aggregate()`.

Since Aggregates are expressions and wrap expressions, you can represent some complex computations:

```
from django.db.models import Count

Company.objects.annotate(
    managers_required=(Count('num_employees') / 4) + Count('num_managers'))
```

The Aggregate API is as follows:

```
class Aggregate(expression, output_field=None, **extra)
```

#### template

A class attribute, as a format string, that describes the SQL that is generated for this aggregate. Defaults to `'%(function)s( %(expressions)s )'`.

#### function

A class attribute describing the aggregate function that will be generated. Specifically, the function will be interpolated as the `function` placeholder within `template`. Defaults to `None`.

The `expression` argument can be the name of a field on the model, or another expression. It will be converted to a string and used as the `expressions` placeholder within the `template`.

The `output_field` argument requires a model field instance, like `IntegerField()` or `BooleanField()`, into which Django will load the value after it's retrieved from the database. Usually no arguments are needed when instantiating the model field as any arguments relating to data validation (`max_length`, `max_digits`, etc.) will not be enforced on the expression's output value.

Note that `output_field` is only required when Django is unable to determine what field type the result should be. Complex expressions that mix field types should define the desired `output_field`. For example, adding an `IntegerField()` and a `FloatField()` together should probably have `output_field=FloatField()` defined.

The `**extra` kwargs are `key=value` pairs that can be interpolated into the `template` attribute.

## Creating your own Aggregate Functions

Creating your own aggregate is extremely easy. At a minimum, you need to define `function`, but you can also completely customize the SQL that is generated. Here's a brief example:

```
from django.db.models import Aggregate

class Count(Aggregate):
    # supports COUNT(distinct field)
    function = 'COUNT'
    template = '%(function)s(%(distinct)s%(expressions)s)'

    def __init__(self, expression, distinct=False, **extra):
        super(Count, self).__init__(
            expression,
            distinct='DISTINCT ' if distinct else '',
            output_field=IntegerField(),
            **extra
        )
```

## Value() expressions

```
class Value(value, output_field=None)
```

A `Value()` object represents the smallest possible component of an expression: a simple value. When you need to represent the value of an integer, boolean, or string within an expression, you can wrap that value within a `Value()`.

You will rarely need to use `Value()` directly. When you write the expression `F('field') + 1`, Django implicitly wraps the `1` in a `Value()`, allowing simple values to be used in more complex expressions. You will need to use `Value()` when you want to pass a string to an expression. Most expressions interpret a string argument as the name of a field, like `Lower('name')`.

The `value` argument describes the value to be included in the expression, such as `1`, `True`, or `None`. Django knows how to convert these Python values into their corresponding database type.

The `output_field` argument should be a model field instance, like `IntegerField()` or `BooleanField()`, into which Django will load the value after it's retrieved from the database. Usually no arguments are needed when instantiating the model field as any arguments relating to data validation (`max_length`, `max_digits`, etc.) will not be enforced on the expression's output value.

### ExpressionWrapper() expressions

**class** `ExpressionWrapper` (*expression*, *output\_field*)

`ExpressionWrapper` simply surrounds another expression and provides access to properties, such as `output_field`, that may not be available on other expressions. `ExpressionWrapper` is necessary when using arithmetic on `F()` expressions with different types as described in *Using F() with annotations*.

### Conditional expressions

Conditional expressions allow you to use `if ... elif ... else` logic in queries. Django natively supports SQL CASE expressions. For more details see *Conditional Expressions*.

### Raw SQL expressions

**class** `RawSQL` (*sql*, *params*, *output\_field=None*)

Sometimes database expressions can't easily express a complex WHERE clause. In these edge cases, use the `RawSQL` expression. For example:

```
>>> from django.db.models.expressions import RawSQL
>>> queryset.annotate(val=RawSQL("select col from sometable where othercol = %s",
↪ (someparam,)))
```

These extra lookups may not be portable to different database engines (because you're explicitly writing SQL code) and violate the DRY principle, so you should avoid them if possible.

**Warning:** You should be very careful to escape any parameters that the user can control by using `params` in order to protect against *SQL injection attacks*. `params` is a required argument to force you to acknowledge that you're not interpolating your SQL with user provided data.

### Technical Information

Below you'll find technical implementation details that may be useful to library authors. The technical API and examples below will help with creating generic query expressions that can extend the built-in functionality that Django provides.

### Expression API

Query expressions implement the *query expression API*, but also expose a number of extra methods and attributes listed below. All query expressions must inherit from `Expression()` or a relevant subclass.

When a query expression wraps another expression, it is responsible for calling the appropriate methods on the wrapped expression.

### class `Expression`

#### `contains_aggregate`

Tells Django that this expression contains an aggregate and that a `GROUP BY` clause needs to be added to the query.

#### `resolve_expression` (*query=None, allow\_joins=True, reuse=None, summarize=False, for\_save=False*)

Provides the chance to do any pre-processing or validation of the expression before it's added to the query. `resolve_expression()` must also be called on any nested expressions. A `copy()` of `self` should be returned with any necessary transformations.

`query` is the backend query implementation.

`allow_joins` is a boolean that allows or denies the use of joins in the query.

`reuse` is a set of reusable joins for multi-join scenarios.

`summarize` is a boolean that, when `True`, signals that the query being computed is a terminal aggregate query.

#### `get_source_expressions` ()

Returns an ordered list of inner expressions. For example:

```
>>> Sum(F('foo')).get_source_expressions()
[F('foo')]
```

#### `set_source_expressions` (*expressions*)

Takes a list of expressions and stores them such that `get_source_expressions()` can return them.

#### `relabeled_clone` (*change\_map*)

Returns a clone (copy) of `self`, with any column aliases relabeled. Column aliases are renamed when subqueries are created. `relabeled_clone()` should also be called on any nested expressions and assigned to the clone.

`change_map` is a dictionary mapping old aliases to new aliases.

Example:

```
def relabeled_clone(self, change_map):
    clone = copy.copy(self)
    clone.expression = self.expression.relabeled_clone(change_map)
    return clone
```

#### `convert_value` (*self, value, expression, connection, context*)

A hook allowing the expression to coerce `value` into a more appropriate type.

#### `get_group_by_cols` ()

Responsible for returning the list of columns references by this expression. `get_group_by_cols()` should be called on any nested expressions. `F()` objects, in particular, hold a reference to a column.

#### `asc` ()

Returns the expression ready to be sorted in ascending order.

#### `desc` ()

Returns the expression ready to be sorted in descending order.

**reverse\_ordering()**

Returns *self* with any modifications required to reverse the sort order within an `order_by` call. As an example, an expression implementing `NULLS LAST` would change its value to be `NULLS FIRST`. Modifications are only required for expressions that implement sort order like `OrderBy`. This method is called when `reverse()` is called on a queryset.

**Writing your own Query Expressions**

You can write your own query expression classes that use, and can integrate with, other query expressions. Let's step through an example by writing an implementation of the `COALESCE` SQL function, without using the built-in `Func()` expressions.

The `COALESCE` SQL function is defined as taking a list of columns or values. It will return the first column or value that isn't `NULL`.

We'll start by defining the template to be used for SQL generation and an `__init__()` method to set some attributes:

```
import copy
from django.db.models import Expression

class Coalesce(Expression):
    template = 'COALESCE( %(expressions)s )'

    def __init__(self, expressions, output_field):
        super(Coalesce, self).__init__(output_field=output_field)
        if len(expressions) < 2:
            raise ValueError('expressions must have at least 2 elements')
        for expression in expressions:
            if not hasattr(expression, 'resolve_expression'):
                raise TypeError('%r is not an Expression' % expression)
        self.expressions = expressions
```

We do some basic validation on the parameters, including requiring at least 2 columns or values, and ensuring they are expressions. We are requiring `output_field` here so that Django knows what kind of model field to assign the eventual result to.

Now we implement the pre-processing and validation. Since we do not have any of our own validation at this point, we just delegate to the nested expressions:

```
def resolve_expression(self, query=None, allow_joins=True, reuse=None,
    ↪ summarize=False, for_save=False):
    c = self.copy()
    c.is_summary = summarize
    for pos, expression in enumerate(self.expressions):
        c.expressions[pos] = expression.resolve_expression(query, allow_joins, reuse,
    ↪ summarize, for_save)
    return c
```

Next, we write the method responsible for generating the SQL:

```
def as_sql(self, compiler, connection, template=None):
    sql_expressions, sql_params = [], []
    for expression in self.expressions:
        sql, params = compiler.compile(expression)
        sql_expressions.append(sql)
        sql_params.extend(params)
    template = template or self.template
```

```

data = {'expressions': ','.join(sql_expressions)}
return template % data, params

def as_oracle(self, compiler, connection):
    """
    Example of vendor specific handling (Oracle in this case).
    Let's make the function name lowercase.
    """
    return self.as_sql(compiler, connection, template='coalesce( %(expressions)s )')

```

`as_sql()` methods can support custom keyword arguments, allowing `as_vendorname()` methods to override data used to generate the SQL string. Using `as_sql()` keyword arguments for customization is preferable to mutating `self` within `as_vendorname()` methods as the latter can lead to errors when running on different database backends. If your class relies on class attributes to define data, consider allowing overrides in your `as_sql()` method.

We generate the SQL for each of the expressions by using the `compiler.compile()` method, and join the result together with commas. Then the template is filled out with our data and the SQL and parameters are returned.

We've also defined a custom implementation that is specific to the Oracle backend. The `as_oracle()` function will be called instead of `as_sql()` if the Oracle backend is in use.

Finally, we implement the rest of the methods that allow our query expression to play nice with other query expressions:

```

def get_source_expressions(self):
    return self.expressions

def set_source_expressions(self, expressions):
    self.expressions = expressions

```

Let's see how it works:

```

>>> from django.db.models import F, Value, CharField
>>> qs = Company.objects.annotate(
...     tagline=Coalesce([
...         F('motto'),
...         F('ticker_name'),
...         F('description'),
...         Value('No Tagline')
...     ], output_field=CharField())
>>> for c in qs:
...     print("%s: %s" % (c.name, c.tagline))
...
Google: Do No Evil
Apple: AAPL
Yahoo: Internet Company
Django Software Foundation: No Tagline

```

## Adding support in third-party database backends

If you're using a database backend that uses a different SQL syntax for a certain function, you can add support for it by monkey patching a new method onto the function's class.

Let's say we're writing a backend for Microsoft's SQL Server which uses the SQL `LEN` instead of `LENGTH` for the `Length` function. We'll monkey patch a new method called `as_sqlserver()` onto the `Length` class:

```

from django.db.models.functions import Length

```

```
def sqlserver_length(self, compiler, connection):
    return self.as_sql(compiler, connection, function='LEN')
```

```
Length.as_sqlserver = sqlserver_length
```

You can also customize the SQL using the `template` parameter of `as_sql()`.

We use `as_sqlserver()` because `django.db.connection.vendor` returns `sqlserver` for the backend.

Third-party backends can register their functions in the top level `__init__.py` file of the backend package or in a top level `expressions.py` file (or package) that is imported from the top level `__init__.py`.

For user projects wishing to patch the backend that they're using, this code should live in an `AppConfig.ready()` method.

### 6.15.11 Conditional Expressions

Conditional expressions let you use `if ... elif ... else` logic within filters, annotations, aggregations, and updates. A conditional expression evaluates a series of conditions for each row of a table and returns the matching result expression. Conditional expressions can also be combined and nested like other *expressions*.

#### The conditional expression classes

We'll be using the following model in the subsequent examples:

```
from django.db import models

class Client(models.Model):
    REGULAR = 'R'
    GOLD = 'G'
    PLATINUM = 'P'
    ACCOUNT_TYPE_CHOICES = (
        (REGULAR, 'Regular'),
        (GOLD, 'Gold'),
        (PLATINUM, 'Platinum'),
    )
    name = models.CharField(max_length=50)
    registered_on = models.DateField()
    account_type = models.CharField(
        max_length=1,
        choices=ACCOUNT_TYPE_CHOICES,
        default=REGULAR,
    )
```

#### When

```
class When(condition=None, then=None, **lookups)
```

A `When()` object is used to encapsulate a condition and its result for use in the conditional expression. Using a `When()` object is similar to using the `filter()` method. The condition can be specified using *field lookups* or *Q* objects. The result is provided using the `then` keyword.

Some examples:

```
>>> from django.db.models import When, F, Q
>>> # String arguments refer to fields; the following two examples are equivalent:
>>> When(account_type=Client.GOLD, then='name')
>>> When(account_type=Client.GOLD, then=F('name'))
>>> # You can use field lookups in the condition
>>> from datetime import date
>>> When(registered_on__gt=date(2014, 1, 1),
...     registered_on__lt=date(2015, 1, 1),
...     then='account_type')
>>> # Complex conditions can be created using Q objects
>>> When(Q(name__startswith="John") | Q(name__startswith="Paul"),
...     then='name')
```

Keep in mind that each of these values can be an expression.

**Note:** Since the `then` keyword argument is reserved for the result of the `When()`, there is a potential conflict if a `Model` has a field named `then`. This can be resolved in two ways:

```
>>> When(then__exact=0, then=1)
>>> When(Q(then=0), then=1)
```

## Case

**class Case** (\*cases, \*\*extra)

A `Case()` expression is like the `if ... elif ... else` statement in Python. Each condition in the provided `When()` objects is evaluated in order, until one evaluates to a truthful value. The result expression from the matching `When()` object is returned.

A simple example:

```
>>>
>>> from datetime import date, timedelta
>>> from django.db.models import CharField, Case, Value, When
>>> Client.objects.create(
...     name='Jane Doe',
...     account_type=Client.REGULAR,
...     registered_on=date.today() - timedelta(days=36))
>>> Client.objects.create(
...     name='James Smith',
...     account_type=Client.GOLD,
...     registered_on=date.today() - timedelta(days=5))
>>> Client.objects.create(
...     name='Jack Black',
...     account_type=Client.PLATINUM,
...     registered_on=date.today() - timedelta(days=10 * 365))
>>> # Get the discount for each Client based on the account type
>>> Client.objects.annotate(
...     discount=Case(
...         When(account_type=Client.GOLD, then=Value('5%')),
...         When(account_type=Client.PLATINUM, then=Value('10%')),
...         default=Value('0%'),
...         output_field=CharField(),
...     ),
```

```
... ).values_list('name', 'discount')
[('Jane Doe', '0%'), ('James Smith', '5%'), ('Jack Black', '10%')]
```

`Case()` accepts any number of `When()` objects as individual arguments. Other options are provided using keyword arguments. If none of the conditions evaluate to `TRUE`, then the expression given with the `default` keyword argument is returned. If a `default` argument isn't provided, `None` is used.

If we wanted to change our previous query to get the discount based on how long the `Client` has been with us, we could do so using lookups:

```
>>> a_month_ago = date.today() - timedelta(days=30)
>>> a_year_ago = date.today() - timedelta(days=365)
>>> # Get the discount for each Client based on the registration date
>>> Client.objects.annotate(
...     discount=Case(
...         When(registered_on__lte=a_year_ago, then=Value('10%')),
...         When(registered_on__lte=a_month_ago, then=Value('5%')),
...         default=Value('0%'),
...         output_field=CharField(),
...     )
... ).values_list('name', 'discount')
[('Jane Doe', '5%'), ('James Smith', '0%'), ('Jack Black', '10%')]
```

---

**Note:** Remember that the conditions are evaluated in order, so in the above example we get the correct result even though the second condition matches both Jane Doe and Jack Black. This works just like an `if ... elif ... else` statement in Python.

---

`Case()` also works in a `filter()` clause. For example, to find gold clients that registered more than a month ago and platinum clients that registered more than a year ago:

```
>>> a_month_ago = date.today() - timedelta(days=30)
>>> a_year_ago = date.today() - timedelta(days=365)
>>> Client.objects.filter(
...     registered_on__lte=Case(
...         When(account_type=Client.GOLD, then=a_month_ago),
...         When(account_type=Client.PLATINUM, then=a_year_ago),
...     ),
... ).values_list('name', 'account_type')
[('Jack Black', 'P')]
```

## Advanced queries

Conditional expressions can be used in annotations, aggregations, lookups, and updates. They can also be combined and nested with other expressions. This allows you to make powerful conditional queries.

## Conditional update

Let's say we want to change the `account_type` for our clients to match their registration dates. We can do this using a conditional expression and the `update()` method:

```
>>> a_month_ago = date.today() - timedelta(days=30)
>>> a_year_ago = date.today() - timedelta(days=365)
>>> # Update the account_type for each Client from the registration date
```

```
>>> Client.objects.update(
...     account_type=Case(
...         When(registered_on__lte=a_year_ago,
...              then=Value(Client.PLATINUM)),
...         When(registered_on__lte=a_month_ago,
...              then=Value(Client.GOLD)),
...         default=Value(Client.REGULAR)
...     ),
... )
>>> Client.objects.values_list('name', 'account_type')
[('Jane Doe', 'G'), ('James Smith', 'R'), ('Jack Black', 'P')]
```

## Conditional aggregation

What if we want to find out how many clients there are for each `account_type`? We can nest conditional expression within *aggregate functions* to achieve this:

```
>>> # Create some more Clients first so we can have something to count
>>> Client.objects.create(
...     name='Jean Grey',
...     account_type=Client.REGULAR,
...     registered_on=date.today())
>>> Client.objects.create(
...     name='James Bond',
...     account_type=Client.PLATINUM,
...     registered_on=date.today())
>>> Client.objects.create(
...     name='Jane Porter',
...     account_type=Client.PLATINUM,
...     registered_on=date.today())
>>> # Get counts for each value of account_type
>>> from django.db.models import IntegerField, Sum
>>> Client.objects.aggregate(
...     regular=Sum(
...         Case(When(account_type=Client.REGULAR, then=1),
...                output_field=IntegerField())
...     ),
...     gold=Sum(
...         Case(When(account_type=Client.GOLD, then=1),
...                output_field=IntegerField())
...     ),
...     platinum=Sum(
...         Case(When(account_type=Client.PLATINUM, then=1),
...                output_field=IntegerField())
...     )
... )
{'regular': 2, 'gold': 1, 'platinum': 3}
```

### 6.15.12 Database Functions

The classes documented below provide a way for users to use *functions* provided by the underlying database as annotations, aggregations, or filters in Django. Functions are also *expressions*, so they can be used and combined with other expressions like *aggregate functions*.

We'll be using the following model in examples of each function:

```
class Author(models.Model):
    name = models.CharField(max_length=50)
    age = models.PositiveIntegerField(null=True, blank=True)
    alias = models.CharField(max_length=50, null=True, blank=True)
    goes_by = models.CharField(max_length=50, null=True, blank=True)
```

We don't usually recommend allowing `null=True` for `CharField` since this allows the field to have two “empty values”, but it's important for the `Coalesce` example below.

## Cast

```
class Cast(expression, output_field)
```

Forces the result type of `expression` to be the one from `output_field`.

Usage example:

```
>>> from django.db.models import FloatField
>>> from django.db.models.functions import Cast
>>> Value.objects.create(integer=4)
>>> value = Value.objects.annotate(as_float=Cast('integer', FloatField())).get()
>>> print(value.as_float)
4.0
```

## Coalesce

```
class Coalesce(*expressions, **extra)
```

Accepts a list of at least two field names or expressions and returns the first non-null value (note that an empty string is not considered a null value). Each argument must be of a similar type, so mixing text and numbers will result in a database error.

Usage examples:

```
>>> # Get a screen name from least to most public
>>> from django.db.models import Sum, Value as V
>>> from django.db.models.functions import Coalesce
>>> Author.objects.create(name='Margaret Smith', goes_by='Maggie')
>>> author = Author.objects.annotate(
...     screen_name=Coalesce('alias', 'goes_by', 'name')).get()
>>> print(author.screen_name)
Maggie

>>> # Prevent an aggregate Sum() from returning None
>>> aggregated = Author.objects.aggregate(
...     combined_age=Coalesce(Sum('age'), V(0)),
...     combined_age_default=Sum('age'))
>>> print(aggregated['combined_age'])
0
>>> print(aggregated['combined_age_default'])
None
```

**Warning:** A Python value passed to `Coalesce` on MySQL may be converted to an incorrect type unless explicitly cast to the correct database type:

```
>>> from django.db.models import DateTimeField
>>> from django.db.models.functions import Cast, Coalesce
>>> from django.utils import timezone
>>> now = timezone.now()
>>> Coalesce('updated', Cast(now, DateTimeField()))
```

## Concat

**class Concat** (\*expressions, \*\*extra)

Accepts a list of at least two text fields or expressions and returns the concatenated text. Each argument must be of a text or char type. If you want to concatenate a `TextField()` with a `CharField()`, then be sure to tell Django that the `output_field` should be a `TextField()`. This is also required when concatenating a `Value` as in the example below.

This function will never have a null result. On backends where a null argument results in the entire expression being null, Django will ensure that each null part is converted to an empty string first.

Usage example:

```
>>> # Get the display name as "name (goes_by)"
>>> from django.db.models import CharField, Value as V
>>> from django.db.models.functions import Concat
>>> Author.objects.create(name='Margaret Smith', goes_by='Maggie')
>>> author = Author.objects.annotate(
...     screen_name=Concat('name', V(' '), 'goes_by', V(' ')),
...     output_field=CharField()).get()
>>> print(author.screen_name)
Margaret Smith (Maggie)
```

## Greatest

**class Greatest** (\*expressions, \*\*extra)

Accepts a list of at least two field names or expressions and returns the greatest value. Each argument must be of a similar type, so mixing text and numbers will result in a database error.

Usage example:

```
class Blog(models.Model):
    body = models.TextField()
    modified = models.DateTimeField(auto_now=True)

class Comment(models.Model):
    body = models.TextField()
    modified = models.DateTimeField(auto_now=True)
    blog = models.ForeignKey(Blog, on_delete=models.CASCADE)

>>> from django.db.models.functions import Greatest
>>> blog = Blog.objects.create(body='Greatest is the best.')
>>> comment = Comment.objects.create(body='No, Least is better.', blog=blog)
>>> comments = Comment.objects.annotate(last_updated=Greatest('modified', 'blog__
↳modified'))
>>> annotated_comment = comments.get()
```

`annotated_comment.last_updated` will be the most recent of `blog.modified` and `comment.modified`.

**Warning:** The behavior of `Greatest` when one or more expression may be null varies between databases:

- PostgreSQL: `Greatest` will return the largest non-null expression, or null if all expressions are null.
- SQLite, Oracle, and MySQL: If any expression is null, `Greatest` will return null.

The PostgreSQL behavior can be emulated using `Coalesce` if you know a sensible minimum value to provide as a default.

## Least

**class** `Least` (*\*expressions*, *\*\*extra*)

Accepts a list of at least two field names or expressions and returns the least value. Each argument must be of a similar type, so mixing text and numbers will result in a database error.

**Warning:** The behavior of `Least` when one or more expression may be null varies between databases:

- PostgreSQL: `Least` will return the smallest non-null expression, or null if all expressions are null.
- SQLite, Oracle, and MySQL: If any expression is null, `Least` will return null.

The PostgreSQL behavior can be emulated using `Coalesce` if you know a sensible maximum value to provide as a default.

## Length

**class** `Length` (*expression*, *\*\*extra*)

Accepts a single text field or expression and returns the number of characters the value has. If the expression is null, then the length will also be null.

Usage example:

```
>>> # Get the length of the name and goes_by fields
>>> from django.db.models.functions import Length
>>> Author.objects.create(name='Margaret Smith')
>>> author = Author.objects.annotate(
...     name_length=Length('name'),
...     goes_by_length=Length('goes_by')).get()
>>> print(author.name_length, author.goes_by_length)
(14, None)
```

It can also be registered as a transform. For example:

```
>>> from django.db.models import CharField
>>> from django.db.models.functions import Length
>>> CharField.register_lookup(Length, 'length')
>>> # Get authors whose name is longer than 7 characters
>>> authors = Author.objects.filter(name__length__gt=7)
```

The ability to register the function as a transform was added.

## Lower

**class Lower** (*expression*, *\*\*extra*)

Accepts a single text field or expression and returns the lowercase representation.

It can also be registered as a transform as described in [Length](#).

Usage example:

```
>>> from django.db.models.functions import Lower
>>> Author.objects.create(name='Margaret Smith')
>>> author = Author.objects.annotate(name_lower=Lower('name')).get()
>>> print(author.name_lower)
margaret smith
```

The ability to register the function as a transform was added.

## Now

**class Now**

Returns the database server's current date and time when the query is executed, typically using the SQL `CURRENT_TIMESTAMP`.

Usage example:

```
>>> from django.db.models.functions import Now
>>> Article.objects.filter(published__lte=Now())
<QuerySet [ <Article: How to Django > ]>
```

---

## PostgreSQL considerations

On PostgreSQL, the SQL `CURRENT_TIMESTAMP` returns the time that the current transaction started. Therefore for cross-database compatibility, `Now()` uses `STATEMENT_TIMESTAMP` instead. If you need the transaction timestamp, use `django.contrib.postgres.functions.TransactionNow`.

---

## Substr

**class Substr** (*expression*, *pos*, *length=None*, *\*\*extra*)

Returns a substring of length `length` from the field or expression starting at position `pos`. The position is 1-indexed, so the position must be greater than 0. If `length` is `None`, then the rest of the string will be returned.

Usage example:

```
>>> # Set the alias to the first 5 characters of the name as lowercase
>>> from django.db.models.functions import Substr, Lower
>>> Author.objects.create(name='Margaret Smith')
>>> Author.objects.update(alias=Lower(Substr('name', 1, 5)))
1
>>> print(Author.objects.get(name='Margaret Smith').alias)
marga
```

## Upper

**class Upper** (*expression*, *\*\*extra*)

Accepts a single text field or expression and returns the uppercase representation.

It can also be registered as a transform as described in [Length](#).

Usage example:

```
>>> from django.db.models.functions import Upper
>>> Author.objects.create(name='Margaret Smith')
>>> author = Author.objects.annotate(name_upper=Upper('name')).get()
>>> print(author.name_upper)
MARGARET SMITH
```

The ability to register the function as a transform was added.

## Date Functions

We'll be using the following model in examples of each function:

```
class Experiment(models.Model):
    start_datetime = models.DateTimeField()
    start_date = models.DateField(null=True, blank=True)
    end_datetime = models.DateTimeField(null=True, blank=True)
    end_date = models.DateField(null=True, blank=True)
```

## Extract

**class Extract** (*expression*, *lookup\_name=None*, *tzinfo=None*, *\*\*extra*)

Extracts a component of a date as a number.

Takes an *expression* representing a `DateField` or `DateTimeField` and a *lookup\_name*, and returns the part of the date referenced by *lookup\_name* as an `IntegerField`. Django usually uses the databases' `extract` function, so you may use any *lookup\_name* that your database supports. A `tzinfo` subclass, usually provided by `pytz`, can be passed to extract a value in a specific timezone.

Given the datetime `2015-06-15 23:30:01.000321+00:00`, the built-in *lookup\_names* return:

- "year": 2015
- "month": 6
- "day": 15
- "week\_day": 2
- "hour": 23
- "minute": 30
- "second": 1

If a different timezone like `Australia/Melbourne` is active in Django, then the datetime is converted to the timezone before the value is extracted. The timezone offset for Melbourne in the example date above is `+10:00`. The values returned when this timezone is active will be the same as above except for:

- "day": 16

- “week\_day”: 3
- “hour”: 9

---

### week\_day values

The `week_day` lookup\_type is calculated differently from most databases and from Python’s standard functions. This function will return 1 for Sunday, 2 for Monday, through 7 for Saturday.

The equivalent calculation in Python is:

```
>>> from datetime import datetime
>>> dt = datetime(2015, 6, 15)
>>> (dt.isoweekday() % 7) + 1
2
```

Each lookup\_name above has a corresponding Extract subclass (listed below) that should typically be used instead of the more verbose equivalent, e.g. use `ExtractYear(...)` rather than `Extract(..., lookup_name='year')`.

Usage example:

```
>>> from datetime import datetime
>>> from django.db.models.functions import Extract
>>> start = datetime(2015, 6, 15)
>>> end = datetime(2015, 7, 2)
>>> Experiment.objects.create(
...     start_datetime=start, start_date=start.date(),
...     end_datetime=end, end_date=end.date())
>>> # Add the experiment start year as a field in the QuerySet.
>>> experiment = Experiment.objects.annotate(
...     start_year=Extract('start_datetime', 'year')).get()
>>> experiment.start_year
2015
>>> # How many experiments completed in the same year in which they started?
>>> Experiment.objects.filter(
...     start_datetime__year=Extract('end_datetime', 'year')).count()
1
```

### DateField extracts

```
class ExtractYear (expression, tzinfo=None, **extra)
```

```
    lookup_name = 'year'
```

```
class ExtractMonth (expression, tzinfo=None, **extra)
```

```
    lookup_name = 'month'
```

```
class ExtractDay (expression, tzinfo=None, **extra)
```

```
    lookup_name = 'day'
```

```
class ExtractWeekDay (expression, tzinfo=None, **extra)
```

```
lookup_name = 'week_day'
```

These are logically equivalent to `Extract('date_field', lookup_name)`. Each class is also a Transform registered on `DateField` and `DateTimeField` as `__(lookup_name)`, e.g. `__year`.

Since `DateFields` don't have a time component, only `Extract` subclasses that deal with date-parts can be used with `DateField`:

```
>>> from datetime import datetime
>>> from django.utils import timezone
>>> from django.db.models.functions import (
...     ExtractYear, ExtractMonth, ExtractDay, ExtractWeekDay
... )
>>> start_2015 = datetime(2015, 6, 15, 23, 30, 1, tzinfo=timezone.utc)
>>> end_2015 = datetime(2015, 6, 16, 13, 11, 27, tzinfo=timezone.utc)
>>> Experiment.objects.create(
...     start_datetime=start_2015, start_date=start_2015.date(),
...     end_datetime=end_2015, end_date=end_2015.date())
>>> Experiment.objects.annotate(
...     year=ExtractYear('start_date'),
...     month=ExtractMonth('start_date'),
...     day=ExtractDay('start_date'),
...     weekday=ExtractWeekDay('start_date'),
... ).values('year', 'month', 'day', 'weekday').get(
...     end_date__year=ExtractYear('start_date'),
... )
{'year': 2015, 'month': 6, 'day': 15, 'weekday': 2}
```

### DateTimeField extracts

In addition to the following, all extracts for `DateField` listed above may also be used on `DateTimeFields`.

```
class ExtractHour(expression, tzinfo=None, **extra)
```

```
lookup_name = 'hour'
```

```
class ExtractMinute(expression, tzinfo=None, **extra)
```

```
lookup_name = 'minute'
```

```
class ExtractSecond(expression, tzinfo=None, **extra)
```

```
lookup_name = 'second'
```

These are logically equivalent to `Extract('datetime_field', lookup_name)`. Each class is also a Transform registered on `DateTimeField` as `__(lookup_name)`, e.g. `__minute`.

`DateTimeField` examples:

```
>>> from datetime import datetime
>>> from django.utils import timezone
>>> from django.db.models.functions import (
...     ExtractYear, ExtractMonth, ExtractDay, ExtractWeekDay,
...     ExtractHour, ExtractMinute, ExtractSecond,
... )
>>> start_2015 = datetime(2015, 6, 15, 23, 30, 1, tzinfo=timezone.utc)
>>> end_2015 = datetime(2015, 6, 16, 13, 11, 27, tzinfo=timezone.utc)
```

```
>>> Experiment.objects.create(
...     start_datetime=start_2015, start_date=start_2015.date(),
...     end_datetime=end_2015, end_date=end_2015.date())
>>> Experiment.objects.annotate(
...     year=ExtractYear('start_datetime'),
...     month=ExtractMonth('start_datetime'),
...     day=ExtractDay('start_datetime'),
...     weekday=ExtractWeekDay('start_datetime'),
...     hour=ExtractHour('start_datetime'),
...     minute=ExtractMinute('start_datetime'),
...     second=ExtractSecond('start_datetime'),
... ).values(
...     'year', 'month', 'day', 'weekday', 'hour', 'minute', 'second',
... ).get(end_datetime__year=ExtractYear('start_datetime'))
{'year': 2015, 'month': 6, 'day': 15, 'weekday': 2, 'hour': 23, 'minute': 30, 'second
↪': 1}
```

When `USE_TZ` is `True` then datetimes are stored in the database in UTC. If a different timezone is active in Django, the datetime is converted to that timezone before the value is extracted. The example below converts to the Melbourne timezone (UTC +10:00), which changes the day, weekday, and hour values that are returned:

```
>>> import pytz
>>> melb = pytz.timezone('Australia/Melbourne') # UTC+10:00
>>> with timezone.override(melb):
...     Experiment.objects.annotate(
...         day=ExtractDay('start_datetime'),
...         weekday=ExtractWeekDay('start_datetime'),
...         hour=ExtractHour('start_datetime'),
...     ).values('day', 'weekday', 'hour').get(
...         end_datetime__year=ExtractYear('start_datetime'),
...     )
{'day': 16, 'weekday': 3, 'hour': 9}
```

Explicitly passing the timezone to the `Extract` function behaves in the same way, and takes priority over an active timezone:

```
>>> import pytz
>>> melb = pytz.timezone('Australia/Melbourne')
>>> Experiment.objects.annotate(
...     day=ExtractDay('start_datetime', tzinfo=melb),
...     weekday=ExtractWeekDay('start_datetime', tzinfo=melb),
...     hour=ExtractHour('start_datetime', tzinfo=melb),
... ).values('day', 'weekday', 'hour').get(
...     end_datetime__year=ExtractYear('start_datetime'),
... )
{'day': 16, 'weekday': 3, 'hour': 9}
```

## Trunc

**class Trunc** (*expression, kind, output\_field=None, tzinfo=None, \*\*extra*)

Truncates a date up to a significant component.

When you only care if something happened in a particular year, hour, or day, but not the exact second, then `Trunc` (and its subclasses) can be useful to filter or aggregate your data. For example, you can use `Trunc` to calculate the number of sales per day.

`Trunc` takes a single expression, representing a `DateField` or `DateTimeField`, a kind representing a date part, and an `output_field` that's either `DateTimeField()` or `DateField()`. It returns a datetime or date, depending on `output_field`, with fields up to `kind` set to their minimum value. If `output_field` is omitted, it will default to the `output_field` of expression. A `tzinfo` subclass, usually provided by `pytz`, can be passed to truncate a value in a specific timezone.

Given the datetime `2015-06-15 14:30:50.000321+00:00`, the built-in kinds return:

- “year”: 2015-01-01 00:00:00+00:00
- “month”: 2015-06-01 00:00:00+00:00
- “day”: 2015-06-15 00:00:00+00:00
- “hour”: 2015-06-15 14:00:00+00:00
- “minute”: 2015-06-15 14:30:00+00:00
- “second”: 2015-06-15 14:30:50+00:00

If a different timezone like `Australia/Melbourne` is active in Django, then the datetime is converted to the new timezone before the value is truncated. The timezone offset for Melbourne in the example date above is `+10:00`. The values returned when this timezone is active will be:

- “year”: 2015-01-01 00:00:00+11:00
- “month”: 2015-06-01 00:00:00+10:00
- “day”: 2015-06-16 00:00:00+10:00
- “hour”: 2015-06-16 00:00:00+10:00
- “minute”: 2015-06-16 00:30:00+10:00
- “second”: 2015-06-16 00:30:50+10:00

The year has an offset of `+11:00` because the result transitioned into daylight saving time.

Each kind above has a corresponding `Trunc` subclass (listed below) that should typically be used instead of the more verbose equivalent, e.g. use `TruncYear(...)` rather than `Trunc(..., kind='year')`.

The subclasses are all defined as transforms, but they aren't registered with any fields, because the obvious lookup names are already reserved by the `Extract` subclasses.

Usage example:

```
>>> from datetime import datetime
>>> from django.db.models import Count, DateTimeField
>>> from django.db.models.functions import Trunc
>>> Experiment.objects.create(start_datetime=datetime(2015, 6, 15, 14, 30, 50, 321))
>>> Experiment.objects.create(start_datetime=datetime(2015, 6, 15, 14, 40, 2, 123))
>>> Experiment.objects.create(start_datetime=datetime(2015, 12, 25, 10, 5, 27, 999))
>>> experiments_per_day = Experiment.objects.annotate(
...     start_day=Trunc('start_datetime', 'day', output_field=DateTimeField())
... ).values('start_day').annotate(experiments=Count('id'))
>>> for exp in experiments_per_day:
...     print(exp['start_day'], exp['experiments'])
...
2015-06-15 00:00:00 2
2015-12-25 00:00:00 1
>>> experiments = Experiment.objects.annotate(
...     start_day=Trunc('start_datetime', 'day', output_field=DateTimeField())
... ).filter(start_day=datetime(2015, 6, 15))
>>> for exp in experiments:
```

```
...     print(exp.start_datetime)
...
2015-06-15 14:30:50.000321
2015-06-15 14:40:02.000123
```

### DateField truncation

```
class TruncYear(expression, output_field=None, tzinfo=None, **extra)
```

```
    kind = 'year'
```

```
class TruncMonth(expression, output_field=None, tzinfo=None, **extra)
```

```
    kind = 'month'
```

These are logically equivalent to `Trunc('date_field', kind)`. They truncate all parts of the date up to `kind` which allows grouping or filtering dates with less precision. `expression` can have an `output_field` of either `DateField` or `DateTimeField`.

Since `DateFields` don't have a time component, only `Trunc` subclasses that deal with date-parts can be used with `DateField`:

```
>>> from datetime import datetime
>>> from django.db.models import Count
>>> from django.db.models.functions import TruncMonth, TruncYear
>>> from django.utils import timezone
>>> start1 = datetime(2014, 6, 15, 14, 30, 50, 321, tzinfo=timezone.utc)
>>> start2 = datetime(2015, 6, 15, 14, 40, 2, 123, tzinfo=timezone.utc)
>>> start3 = datetime(2015, 12, 31, 17, 5, 27, 999, tzinfo=timezone.utc)
>>> Experiment.objects.create(start_datetime=start1, start_date=start1.date())
>>> Experiment.objects.create(start_datetime=start2, start_date=start2.date())
>>> Experiment.objects.create(start_datetime=start3, start_date=start3.date())
>>> experiments_per_year = Experiment.objects.annotate(
...     year=TruncYear('start_date')).values('year').annotate(
...     experiments=Count('id'))
>>> for exp in experiments_per_year:
...     print(exp['year'], exp['experiments'])
...
2014-01-01 1
2015-01-01 2

>>> import pytz
>>> melb = pytz.timezone('Australia/Melbourne')
>>> experiments_per_month = Experiment.objects.annotate(
...     month=TruncMonth('start_datetime', tzinfo=melb)).values('month').annotate(
...     experiments=Count('id'))
>>> for exp in experiments_per_month:
...     print(exp['month'], exp['experiments'])
...
2015-06-01 00:00:00+10:00 1
2016-01-01 00:00:00+11:00 1
2014-06-01 00:00:00+10:00 1
```

## DateTimeField truncation

```
class TruncDate (expression, **extra)
```

```
    lookup_name = 'date'
    output_field = DateField()
```

TruncDate casts expression to a date rather than using the built-in SQL truncate function. It's also registered as a transform on DateTimeField as `__date`.

```
class TruncDay (expression, output_field=None, tzinfo=None, **extra)
```

```
    kind = 'day'
```

```
class TruncHour (expression, output_field=None, tzinfo=None, **extra)
```

```
    kind = 'hour'
```

```
class TruncMinute (expression, output_field=None, tzinfo=None, **extra)
```

```
    kind = 'minute'
```

```
class TruncSecond (expression, output_field=None, tzinfo=None, **extra)
```

```
    kind = 'second'
```

These are logically equivalent to `Trunc('datetime_field', kind)`. They truncate all parts of the date up to kind and allow grouping or filtering datetimes with less precision. expression must have an output\_field of DateTimeField.

Usage example:

```
>>> from datetime import date, datetime
>>> from django.db.models import Count
>>> from django.db.models.functions import (
...     TruncDate, TruncDay, TruncHour, TruncMinute, TruncSecond,
... )
>>> from django.utils import timezone
>>> import pytz
>>> start1 = datetime(2014, 6, 15, 14, 30, 50, 321, tzinfo=timezone.utc)
>>> Experiment.objects.create(start_datetime=start1, start_date=start1.date())
>>> melb = pytz.timezone('Australia/Melbourne')
>>> Experiment.objects.annotate(
...     date=TruncDate('start_datetime'),
...     day=TruncDay('start_datetime', tzinfo=melb),
...     hour=TruncHour('start_datetime', tzinfo=melb),
...     minute=TruncMinute('start_datetime'),
...     second=TruncSecond('start_datetime'),
... ).values('date', 'day', 'hour', 'minute', 'second').get()
{'date': datetime.date(2014, 6, 15),
 'day': datetime.datetime(2014, 6, 16, 0, 0, tzinfo=<DstTzInfo 'Australia/Melbourne'
↪AEST+10:00:00 STD>),
 'hour': datetime.datetime(2014, 6, 16, 0, 0, tzinfo=<DstTzInfo 'Australia/Melbourne'
↪AEST+10:00:00 STD>),
 'minute': 'minute': datetime.datetime(2014, 6, 15, 14, 30, tzinfo=<UTC>),
```

```
'second': datetime.datetime(2014, 6, 15, 14, 30, 50, tzinfo=<UTC>)
}
```

## 6.16 Request and response objects

### 6.16.1 Quick overview

Django uses request and response objects to pass state through the system.

When a page is requested, Django creates an *HttpRequest* object that contains metadata about the request. Then Django loads the appropriate view, passing the *HttpRequest* as the first argument to the view function. Each view is responsible for returning an *HttpResponse* object.

This document explains the APIs for *HttpRequest* and *HttpResponse* objects, which are defined in the *django.http* module.

### 6.16.2 HttpRequest objects

**class *HttpRequest***

#### Attributes

All attributes should be considered read-only, unless stated otherwise.

*HttpRequest*.**scheme**

A string representing the scheme of the request (`http` or `https` usually).

*HttpRequest*.**body**

The raw HTTP request body as a byte string. This is useful for processing data in different ways than conventional HTML forms: binary images, XML payload etc. For processing conventional form data, use *HttpRequest*.`POST`.

You can also read from an *HttpRequest* using a file-like interface. See *HttpRequest*.`read()`.

*HttpRequest*.**path**

A string representing the full path to the requested page, not including the scheme or domain.

Example: `"/music/bands/the_beatles/"`

*HttpRequest*.**path\_info**

Under some Web server configurations, the portion of the URL after the host name is split up into a script prefix portion and a path info portion. The `path_info` attribute always contains the path info portion of the path, no matter what Web server is being used. Using this instead of `path` can make your code easier to move between test and deployment servers.

For example, if the `WSGIScriptAlias` for your application is set to `"/minfo"`, then `path` might be `"/minfo/music/bands/the_beatles/"` and `path_info` would be `"/music/bands/the_beatles/"`.

*HttpRequest*.**method**

A string representing the HTTP method used in the request. This is guaranteed to be uppercase. Example:

```
if request.method == 'GET':
    do_something()
elif request.method == 'POST':
    do_something_else()
```

**HttpRequest.encoding**

A string representing the current encoding used to decode form submission data (or `None`, which means the `DEFAULT_CHARSET` setting is used). You can write to this attribute to change the encoding used when accessing the form data. Any subsequent attribute accesses (such as reading from `GET` or `POST`) will use the new encoding value. Useful if you know the form data is not in the `DEFAULT_CHARSET` encoding.

**HttpRequest.content\_type**

A string representing the MIME type of the request, parsed from the `CONTENT_TYPE` header.

**HttpRequest.content\_params**

A dictionary of key/value parameters included in the `CONTENT_TYPE` header.

**HttpRequest.GET**

A dictionary-like object containing all given HTTP GET parameters. See the *QueryDict* documentation below.

**HttpRequest.POST**

A dictionary-like object containing all given HTTP POST parameters, providing that the request contains form data. See the *QueryDict* documentation below. If you need to access raw or non-form data posted in the request, access this through the `HttpRequest.body` attribute instead.

It's possible that a request can come in via POST with an empty `POST` dictionary – if, say, a form is requested via the POST HTTP method but does not include form data. Therefore, you shouldn't use `if request.POST` to check for use of the POST method; instead, use `if request.method == "POST"` (see above).

Note: POST does *not* include file-upload information. See `FILES`.

**HttpRequest.COOKIES**

A standard Python dictionary containing all cookies. Keys and values are strings.

**HttpRequest.FILES**

A dictionary-like object containing all uploaded files. Each key in `FILES` is the name from the `<input type="file" name="" />`. Each value in `FILES` is an *UploadedFile*.

See *Managing files* for more information.

Note that `FILES` will only contain data if the request method was `POST` and the `<form>` that posted to the request had `enctype="multipart/form-data"`. Otherwise, `FILES` will be a blank dictionary-like object.

**HttpRequest.META**

A standard Python dictionary containing all available HTTP headers. Available headers depend on the client and server, but here are some examples:

- `CONTENT_LENGTH` – The length of the request body (as a string).
- `CONTENT_TYPE` – The MIME type of the request body.
- `HTTP_ACCEPT` – Acceptable content types for the response.
- `HTTP_ACCEPT_ENCODING` – Acceptable encodings for the response.
- `HTTP_ACCEPT_LANGUAGE` – Acceptable languages for the response.
- `HTTP_HOST` – The HTTP Host header sent by the client.
- `HTTP_REFERER` – The referring page, if any.

- `HTTP_USER_AGENT` – The client’s user-agent string.
- `QUERY_STRING` – The query string, as a single (unparsed) string.
- `REMOTE_ADDR` – The IP address of the client.
- `REMOTE_HOST` – The hostname of the client.
- `REMOTE_USER` – The user authenticated by the Web server, if any.
- `REQUEST_METHOD` – A string such as "GET" or "POST".
- `SERVER_NAME` – The hostname of the server.
- `SERVER_PORT` – The port of the server (as a string).

With the exception of `CONTENT_LENGTH` and `CONTENT_TYPE`, as given above, any HTTP headers in the request are converted to `META` keys by converting all characters to uppercase, replacing any hyphens with underscores and adding an `HTTP_` prefix to the name. So, for example, a header called `X-Bender` would be mapped to the `META` key `HTTP_X_BENDER`.

Note that `runserver` strips all headers with underscores in the name, so you won’t see them in `META`. This prevents header-spoofing based on ambiguity between underscores and dashes both being normalizing to underscores in WSGI environment variables. It matches the behavior of Web servers like Nginx and Apache 2.4+.

#### `HttpRequest.resolver_match`

An instance of `ResolverMatch` representing the resolved URL. This attribute is only set after URL resolving took place, which means it’s available in all views but not in middleware which are executed before URL resolving takes place (you can use it in `process_view()` though).

### Attributes set by application code

Django doesn’t set these attributes itself but makes use of them if set by your application.

#### `HttpRequest.current_app`

The `url` template tag will use its value as the `current_app` argument to `reverse()`.

#### `HttpRequest.urlconf`

This will be used as the root URLconf for the current request, overriding the `ROOT_URLCONF` setting. See *How Django processes a request* for details.

`urlconf` can be set to `None` to revert any changes made by previous middleware and return to using the `ROOT_URLCONF`.

Setting `urlconf=None` raised `ImproperlyConfigured` in older versions.

### Attributes set by middleware

Some of the middleware included in Django’s contrib apps set attributes on the request. If you don’t see the attribute on a request, be sure the appropriate middleware class is listed in `MIDDLEWARE`.

#### `HttpRequest.session`

From the `SessionMiddleware`: A readable and writable, dictionary-like object that represents the current session.

#### `HttpRequest.site`

From the `CurrentSiteMiddleware`: An instance of `Site` or `RequestSite` as returned by `get_current_site()` representing the current site.

**HttpRequest.user**

From the *AuthenticationMiddleware*: An instance of `AUTH_USER_MODEL` representing the currently logged-in user. If the user isn't currently logged in, `user` will be set to an instance of `AnonymousUser`. You can tell them apart with `is_authenticated`, like so:

```
if request.user.is_authenticated:
    ... # Do something for logged-in users.
else:
    ... # Do something for anonymous users.
```

## Methods

**HttpRequest.get\_host()**

Returns the originating host of the request using information from the `HTTP_X_FORWARDED_HOST` (if `USE_X_FORWARDED_HOST` is enabled) and `HTTP_HOST` headers, in that order. If they don't provide a value, the method uses a combination of `SERVER_NAME` and `SERVER_PORT` as detailed in [PEP 3333](#).

Example: "127.0.0.1:8000"

---

**Note:** The `get_host()` method fails when the host is behind multiple proxies. One solution is to use middleware to rewrite the proxy headers, as in the following example:

```
from django.utils.deprecation import MiddlewareMixin

class MultipleProxyMiddleware(MiddlewareMixin):
    FORWARDED_FOR_FIELDS = [
        'HTTP_X_FORWARDED_FOR',
        'HTTP_X_FORWARDED_HOST',
        'HTTP_X_FORWARDED_SERVER',
    ]

    def process_request(self, request):
        """
        Rewrites the proxy headers so that only the most
        recent proxy is used.
        """
        for field in self.FORWARDED_FOR_FIELDS:
            if field in request.META:
                if ',' in request.META[field]:
                    parts = request.META[field].split(',')
                    request.META[field] = parts[-1].strip()
```

This middleware should be positioned before any other middleware that relies on the value of `get_host()` – for instance, `CommonMiddleware` or `CsrfViewMiddleware`.

---

**HttpRequest.get\_port()**

Returns the originating port of the request using information from the `HTTP_X_FORWARDED_PORT` (if `USE_X_FORWARDED_PORT` is enabled) and `SERVER_PORT` META variables, in that order.

**HttpRequest.get\_full\_path()**

Returns the path, plus an appended query string, if applicable.

Example: "/music/bands/the\_beatles/?print=true"

**HttpRequest.build\_absolute\_uri(location)**

Returns the absolute URI form of `location`. If no location is provided, the location will be set to `request.get_full_path()`.

If the location is already an absolute URI, it will not be altered. Otherwise the absolute URI is built using the server variables available in this request.

Example: `"https://example.com/music/bands/the_beatles/?print=true"`

---

**Note:** Mixing HTTP and HTTPS on the same site is discouraged, therefore `build_absolute_uri()` will always generate an absolute URI with the same scheme the current request has. If you need to redirect users to HTTPS, it's best to let your Web server redirect all HTTP traffic to HTTPS.

---

`HttpRequest.get_signed_cookie(key, default=RAISE_ERROR, salt='', max_age=None)`

Returns a cookie value for a signed cookie, or raises a `django.core.signing.BadSignature` exception if the signature is no longer valid. If you provide the `default` argument the exception will be suppressed and that default value will be returned instead.

The optional `salt` argument can be used to provide extra protection against brute force attacks on your secret key. If supplied, the `max_age` argument will be checked against the signed timestamp attached to the cookie value to ensure the cookie is not older than `max_age` seconds.

For example:

```
>>> request.get_signed_cookie('name')
'Tony'
>>> request.get_signed_cookie('name', salt='name-salt')
'Tony' # assuming cookie was set using the same salt
>>> request.get_signed_cookie('non-existing-cookie')
...
KeyError: 'non-existing-cookie'
>>> request.get_signed_cookie('non-existing-cookie', False)
False
>>> request.get_signed_cookie('cookie-that-was-tampered-with')
...
BadSignature: ...
>>> request.get_signed_cookie('name', max_age=60)
...
SignatureExpired: Signature age 1677.3839159 > 60 seconds
>>> request.get_signed_cookie('name', False, max_age=60)
False
```

See [cryptographic signing](#) for more information.

`HttpRequest.is_secure()`

Returns True if the request is secure; that is, if it was made with HTTPS.

`HttpRequest.is_ajax()`

Returns True if the request was made via an `XMLHttpRequest`, by checking the `HTTP_X_REQUESTED_WITH` header for the string `'XMLHttpRequest'`. Most modern JavaScript libraries send this header. If you write your own `XMLHttpRequest` call (on the browser side), you'll have to set this header manually if you want `is_ajax()` to work.

If a response varies on whether or not it's requested via AJAX and you are using some form of caching like Django's [cache middleware](#), you should decorate the view with `vary_on_headers('X-Requested-With')` so that the responses are properly cached.

`HttpRequest.read(size=None)`

`HttpRequest.readline()`

`HttpRequest.readlines()`

`HttpRequest.xreadlines()`

`HttpRequest.__iter__()`

Methods implementing a file-like interface for reading from an `HttpRequest` instance. This makes it possible to consume an incoming request in a streaming fashion. A common use-case would be to process a big XML payload with an iterative parser without constructing a whole XML tree in memory.

Given this standard interface, an `HttpRequest` instance can be passed directly to an XML parser such as `ElementTree`:

```
import xml.etree.ElementTree as ET
for element in ET.iterparse(request):
    process(element)
```

### 6.16.3 QueryDict objects

#### class QueryDict

In an `HttpRequest` object, the `GET` and `POST` attributes are instances of `django.http.QueryDict`, a dictionary-like class customized to deal with multiple values for the same key. This is necessary because some HTML form elements, notably `<select multiple>`, pass multiple values for the same key.

The `QueryDicts` at `request.POST` and `request.GET` will be immutable when accessed in a normal request/response cycle. To get a mutable version you need to use `.copy()`.

#### Methods

`QueryDict` implements all the standard dictionary methods because it's a subclass of dictionary. Exceptions are outlined here:

`QueryDict.__init__(query_string=None, mutable=False, encoding=None)`

Instantiates a `QueryDict` object based on `query_string`.

```
>>> QueryDict('a=1&a=2&c=3')
<QueryDict: {'a': ['1', '2'], 'c': ['3']}>
```

If `query_string` is not passed in, the resulting `QueryDict` will be empty (it will have no keys or values).

Most `QueryDicts` you encounter, and in particular those at `request.POST` and `request.GET`, will be immutable. If you are instantiating one yourself, you can make it mutable by passing `mutable=True` to its `__init__()`.

Strings for setting both keys and values will be converted from encoding to unicode. If encoding is not set, it defaults to `DEFAULT_CHARSET`.

`QueryDict.__getitem__(key)`

Returns the value for the given key. If the key has more than one value, `__getitem__()` returns the last value. Raises `django.utils.datastructures.MultiValueDictKeyError` if the key does not exist. (This is a subclass of Python's standard `KeyError`, so you can stick to catching `KeyError`.)

`QueryDict.__setitem__(key, value)`

Sets the given key to `[value]` (a Python list whose single element is `value`). Note that this, as other dictionary functions that have side effects, can only be called on a mutable `QueryDict` (such as one that was created via `copy()`).

`QueryDict.__contains__(key)`

Returns True if the given key is set. This lets you do, e.g., `if "foo" in request.GET`.

`QueryDict.get(key, default=None)`

Uses the same logic as `__getitem__()` above, with a hook for returning a default value if the key doesn't exist.

`QueryDict.setdefault(key, default=None)`

Just like the standard dictionary `setdefault()` method, except it uses `__setitem__()` internally.

`QueryDict.update(other_dict)`

Takes either a `QueryDict` or standard dictionary. Just like the standard dictionary `update()` method, except it *appends* to the current dictionary items rather than replacing them. For example:

```
>>> q = QueryDict('a=1', mutable=True)
>>> q.update({'a': '2'})
>>> q.getlist('a')
['1', '2']
>>> q['a'] # returns the last
'2'
```

`QueryDict.items()`

Just like the standard dictionary `items()` method, except this uses the same last-value logic as `__getitem__()`. For example:

```
>>> q = QueryDict('a=1&a=2&a=3')
>>> q.items()
[('a', '3')]
```

`QueryDict.iteritems()`

Just like the standard dictionary `iteritems()` method. Like `QueryDict.items()` this uses the same last-value logic as `QueryDict.__getitem__()`.

Available only on Python 2.

`QueryDict.iterlists()`

Like `QueryDict.iteritems()` except it includes all values, as a list, for each member of the dictionary.

Available only on Python 2.

`QueryDict.values()`

Just like the standard dictionary `values()` method, except this uses the same last-value logic as `__getitem__()`. For example:

```
>>> q = QueryDict('a=1&a=2&a=3')
>>> q.values()
['3']
```

`QueryDict.itervalues()`

Just like `QueryDict.values()`, except an iterator.

Available only on Python 2.

In addition, `QueryDict` has the following methods:

`QueryDict.copy()`

Returns a copy of the object, using `copy.deepcopy()` from the Python standard library. This copy will be mutable even if the original was not.

`QueryDict.getlist(key, default=None)`

Returns the data with the requested key, as a Python list. Returns an empty list if the key doesn't exist and no

default value was provided. It's guaranteed to return a list of some sort unless the default value provided is not a list.

`QueryDict.setlist(key, list_)`

Sets the given key to `list_` (unlike `__setitem__()`).

`QueryDict.appendlist(key, item)`

Appends an item to the internal list associated with key.

`QueryDict.setlistdefault(key, default_list=None)`

Just like `setdefault`, except it takes a list of values instead of a single value.

`QueryDict.lists()`

Like `items()`, except it includes all values, as a list, for each member of the dictionary. For example:

```
>>> q = QueryDict('a=1&a=2&a=3')
>>> q.lists()
[('a', ['1', '2', '3'])]
```

`QueryDict.pop(key)`

Returns a list of values for the given key and removes them from the dictionary. Raises `KeyError` if the key does not exist. For example:

```
>>> q = QueryDict('a=1&a=2&a=3', mutable=True)
>>> q.pop('a')
['1', '2', '3']
```

`QueryDict.popitem()`

Removes an arbitrary member of the dictionary (since there's no concept of ordering), and returns a two value tuple containing the key and a list of all values for the key. Raises `KeyError` when called on an empty dictionary. For example:

```
>>> q = QueryDict('a=1&a=2&a=3', mutable=True)
>>> q.popitem()
('a', ['1', '2', '3'])
```

`QueryDict.dict()`

Returns dict representation of `QueryDict`. For every (key, list) pair in `QueryDict`, dict will have (key, item), where item is one element of the list, using same logic as `QueryDict.__getitem__()`:

```
>>> q = QueryDict('a=1&a=3&a=5')
>>> q.dict()
{'a': '5'}
```

`QueryDict.urlencode(safe=None)`

Returns a string of the data in query-string format. Example:

```
>>> q = QueryDict('a=2&b=3&b=5')
>>> q.urlencode()
'a=2&b=3&b=5'
```

Optionally, `urlencode` can be passed characters which do not require encoding. For example:

```
>>> q = QueryDict(mutable=True)
>>> q['next'] = '/a&b/'
>>> q.urlencode(safe='/')
'next=/a%26b/'
```

## 6.16.4 HttpResponse objects

### class `HttpResponse`

In contrast to `HttpRequest` objects, which are created automatically by Django, `HttpResponse` objects are your responsibility. Each view you write is responsible for instantiating, populating and returning an `HttpResponse`.

The `HttpResponse` class lives in the `django.http` module.

### Usage

#### Passing strings

Typical usage is to pass the contents of the page, as a string, to the `HttpResponse` constructor:

```
>>> from django.http import HttpResponse
>>> response = HttpResponse("Here's the text of the Web page.")
>>> response = HttpResponse("Text only, please.", content_type="text/plain")
```

But if you want to add content incrementally, you can use `response` as a file-like object:

```
>>> response = HttpResponse()
>>> response.write("<p>Here's the text of the Web page.</p>")
>>> response.write("<p>Here's another paragraph.</p>")
```

#### Passing iterators

Finally, you can pass `HttpResponse` an iterator rather than strings. `HttpResponse` will consume the iterator immediately, store its content as a string, and discard it. Objects with a `close()` method such as files and generators are immediately closed.

If you need the response to be streamed from the iterator to the client, you must use the `StreamingHttpResponse` class instead.

Objects with a `close()` method used to be closed when the WSGI server called `close()` on the response.

#### Setting header fields

To set or remove a header field in your response, treat it like a dictionary:

```
>>> response = HttpResponse()
>>> response['Age'] = 120
>>> del response['Age']
```

Note that unlike a dictionary, `del` doesn't raise `KeyError` if the header field doesn't exist.

For setting the `Cache-Control` and `Vary` header fields, it is recommended to use the `patch_cache_control()` and `patch_vary_headers()` methods from `django.utils.cache`, since these fields can have multiple, comma-separated values. The “patch” methods ensure that other values, e.g. added by a middleware, are not removed.

HTTP header fields cannot contain newlines. An attempt to set a header field containing a newline character (CR or LF) will raise `BadHeaderError`.

## Telling the browser to treat the response as a file attachment

To tell the browser to treat the response as a file attachment, use the `content_type` argument and set the `Content-Disposition` header. For example, this is how you might return a Microsoft Excel spreadsheet:

```
>>> response = HttpResponse(my_data, content_type='application/vnd.ms-excel')
>>> response['Content-Disposition'] = 'attachment; filename="foo.xls"'
```

There's nothing Django-specific about the `Content-Disposition` header, but it's easy to forget the syntax, so we've included it here.

## Attributes

### `HttpResponse.content`

A bytestring representing the content, encoded from a Unicode object if necessary.

### `HttpResponse.charset`

A string denoting the charset in which the response will be encoded. If not given at `HttpResponse` instantiation time, it will be extracted from `content_type` and if that is unsuccessful, the `DEFAULT_CHARSET` setting will be used.

### `HttpResponse.status_code`

The **HTTP status code** for the response.

Unless `reason_phrase` is explicitly set, modifying the value of `status_code` outside the constructor will also modify the value of `reason_phrase`.

### `HttpResponse.reason_phrase`

The HTTP reason phrase for the response.

`reason_phrase` no longer defaults to all capital letters. It now uses the **HTTP standard's** default reason phrases.

Unless explicitly set, `reason_phrase` is determined by the current value of `status_code`.

### `HttpResponse.streaming`

This is always `False`.

This attribute exists so middleware can treat streaming responses differently from regular responses.

### `HttpResponse.closed`

True if the response has been closed.

## Methods

### `HttpResponse.__init__` (*content='', content\_type=None, status=200, reason=None, charset=None*)

Instantiates an `HttpResponse` object with the given page content and content type.

`content` should be an iterator or a string. If it's an iterator, it should return strings, and those strings will be joined together to form the content of the response. If it is not an iterator or a string, it will be converted to a string when accessed.

`content_type` is the MIME type optionally completed by a character set encoding and is used to fill the `HTTP Content-Type` header. If not specified, it is formed by the `DEFAULT_CONTENT_TYPE` and `DEFAULT_CHARSET` settings, by default: `"text/html; charset=utf-8"`.

`status` is the **HTTP status code** for the response.

`reason` is the HTTP response phrase. If not provided, a default phrase will be used.

`charset` is the charset in which the response will be encoded. If not given it will be extracted from `content_type`, and if that is unsuccessful, the `DEFAULT_CHARSET` setting will be used.

`HttpResponse.__getitem__` (*header*, *value*)

Sets the given header name to the given value. Both `header` and `value` should be strings.

`HttpResponse.__delitem__` (*header*)

Deletes the header with the given name. Fails silently if the header doesn't exist. Case-insensitive.

`HttpResponse.__getitem__` (*header*)

Returns the value for the given header name. Case-insensitive.

`HttpResponse.has_header` (*header*)

Returns `True` or `False` based on a case-insensitive check for a header with the given name.

`HttpResponse.setdefault` (*header*, *value*)

Sets a header unless it has already been set.

`HttpResponse.set_cookie` (*key*, *value*=' ', *max\_age*=None, *expires*=None, *path*='/', *domain*=None, *secure*=None, *httponly*=False)

Sets a cookie. The parameters are the same as in the `Morsel` cookie object in the Python standard library.

- `max_age` should be a number of seconds, or `None` (default) if the cookie should last only as long as the client's browser session. If `expires` is not specified, it will be calculated.
- `expires` should either be a string in the format "Wdy, DD-Mon-YY HH:MM:SS GMT" or a `datetime.datetime` object in UTC. If `expires` is a `datetime` object, the `max_age` will be calculated.
- Use `domain` if you want to set a cross-domain cookie. For example, `domain=".lawrence.com"` will set a cookie that is readable by the domains `www.lawrence.com`, `blogs.lawrence.com` and `calendars.lawrence.com`. Otherwise, a cookie will only be readable by the domain that set it.
- Use `httponly=True` if you want to prevent client-side JavaScript from having access to the cookie.

**HTTPOnly** is a flag included in a Set-Cookie HTTP response header. It is not part of the **RFC 2109** standard for cookies, and it isn't honored consistently by all browsers. However, when it is honored, it can be a useful way to mitigate the risk of a client-side script from accessing the protected cookie data.

**Warning:** Both **RFC 2109** and **RFC 6265** state that user agents should support cookies of at least 4096 bytes. For many browsers this is also the maximum size. Django will not raise an exception if there's an attempt to store a cookie of more than 4096 bytes, but many browsers will not set the cookie correctly.

`HttpResponse.set_signed_cookie` (*key*, *value*, *salt*=' ', *max\_age*=None, *expires*=None, *path*='/', *domain*=None, *secure*=None, *httponly*=True)

Like `set_cookie()`, but *cryptographic signing* the cookie before setting it. Use in conjunction with `HttpRequest.get_signed_cookie()`. You can use the optional `salt` argument for added key strength, but you will need to remember to pass it to the corresponding `HttpRequest.get_signed_cookie()` call.

`HttpResponse.delete_cookie` (*key*, *path*='/', *domain*=None)

Deletes the cookie with the given key. Fails silently if the key doesn't exist.

Due to the way cookies work, `path` and `domain` should be the same values you used in `set_cookie()` – otherwise the cookie may not be deleted.

`HttpResponse.write` (*content*)

This method makes an `HttpResponse` instance a file-like object.

`HttpResponse.flush()`

This method makes an *HttpResponse* instance a file-like object.

`HttpResponse.tell()`

This method makes an *HttpResponse* instance a file-like object.

`HttpResponse.getvalue()`

Returns the value of *HttpResponse.content*. This method makes an *HttpResponse* instance a stream-like object.

`HttpResponse.readable()`

Always `False`. This method makes an *HttpResponse* instance a stream-like object.

`HttpResponse.seekable()`

Always `False`. This method makes an *HttpResponse* instance a stream-like object.

`HttpResponse.writable()`

Always `True`. This method makes an *HttpResponse* instance a stream-like object.

`HttpResponse.writelines(lines)`

Writes a list of lines to the response. Line separators are not added. This method makes an *HttpResponse* instance a stream-like object.

## HttpResponse subclasses

Django includes a number of *HttpResponse* subclasses that handle different types of HTTP responses. Like *HttpResponse*, these subclasses live in *django.http*.

### class HttpResponseRedirect

The first argument to the constructor is required – the path to redirect to. This can be a fully qualified URL (e.g. `'https://www.yahoo.com/search/'`), an absolute path with no domain (e.g. `'/search/'`), or even a relative path (e.g. `'search/'`). In that last case, the client browser will reconstruct the full URL itself according to the current path. See *HttpResponse* for other optional constructor arguments. Note that this returns an HTTP status code 302.

#### **url**

This read-only attribute represents the URL the response will redirect to (equivalent to the `Location` response header).

### class HttpResponsePermanentRedirect

Like *HttpResponseRedirect*, but it returns a permanent redirect (HTTP status code 301) instead of a “found” redirect (status code 302).

### class HttpResponseNotModified

The constructor doesn't take any arguments and no content should be added to this response. Use this to designate that a page hasn't been modified since the user's last request (status code 304).

### class HttpResponseBadRequest

Acts just like *HttpResponse* but uses a 400 status code.

### class HttpResponseNotFound

Acts just like *HttpResponse* but uses a 404 status code.

### class HttpResponseForbidden

Acts just like *HttpResponse* but uses a 403 status code.

### class HttpResponseNotAllowed

Like *HttpResponse*, but uses a 405 status code. The first argument to the constructor is required: a list of permitted methods (e.g. `['GET', 'POST']`).

**class `HttpResponseGone`**

Acts just like `HttpResponse` but uses a 410 status code.

**class `HttpResponseServerError`**

Acts just like `HttpResponse` but uses a 500 status code.

---

**Note:** If a custom subclass of `HttpResponse` implements a `render` method, Django will treat it as emulating a `SimpleTemplateResponse`, and the `render` method must itself return a valid response object.

---

## 6.16.5 JsonResponse objects

**class `JsonResponse`** (*data*, *encoder=DjangoJSONEncoder*, *safe=True*, *json\_dumps\_params=None*, *\*\*kwargs*)

An `HttpResponse` subclass that helps to create a JSON-encoded response. It inherits most behavior from its superclass with a couple differences:

Its default `Content-Type` header is set to `application/json`.

The first parameter, *data*, should be a `dict` instance. If the *safe* parameter is set to `False` (see below) it can be any JSON-serializable object.

The *encoder*, which defaults to `django.core.serializers.json.DjangoJSONEncoder`, will be used to serialize the data. See *JSON serialization* for more details about this serializer.

The *safe* boolean parameter defaults to `True`. If it's set to `False`, any object can be passed for serialization (otherwise only `dict` instances are allowed). If *safe* is `True` and a non-`dict` object is passed as the first argument, a `TypeError` will be raised.

The *json\_dumps\_params* parameter is a dictionary of keyword arguments to pass to the `json.dumps()` call used to generate the response.

The *json\_dumps\_params* argument was added.

### Usage

Typical usage could look like:

```
>>> from django.http import JsonResponse
>>> response = JsonResponse({'foo': 'bar'})
>>> response.content
b'{"foo": "bar"}'
```

### Serializing non-dictionary objects

In order to serialize objects other than `dict` you must set the *safe* parameter to `False`:

```
>>> response = JsonResponse([1, 2, 3], safe=False)
```

Without passing `safe=False`, a `TypeError` will be raised.

**Warning:** Before the 5th edition of ECMAScript it was possible to poison the JavaScript `Array` constructor. For this reason, Django does not allow passing non-dict objects to the `JsonResponse` constructor by default. However, most modern browsers implement EcmaScript 5 which removes this attack vector. Therefore it is possible to disable this security precaution.

## Changing the default JSON encoder

If you need to use a different JSON encoder class you can pass the `encoder` parameter to the constructor method:

```
>>> response = JsonResponse(data, encoder=MyJSONEncoder)
```

## 6.16.6 StreamingHttpResponse objects

### class `StreamingHttpResponse`

The `StreamingHttpResponse` class is used to stream a response from Django to the browser. You might want to do this if generating the response takes too long or uses too much memory. For instance, it's useful for *generating large CSV files*.

---

### Performance considerations

Django is designed for short-lived requests. Streaming responses will tie a worker process for the entire duration of the response. This may result in poor performance.

Generally speaking, you should perform expensive tasks outside of the request-response cycle, rather than resorting to a streamed response.

---

The `StreamingHttpResponse` is not a subclass of `HttpResponse`, because it features a slightly different API. However, it is almost identical, with the following notable differences:

- It should be given an iterator that yields strings as content.
- You cannot access its content, except by iterating the response object itself. This should only occur when the response is returned to the client.
- It has no `content` attribute. Instead, it has a `streaming_content` attribute.
- You cannot use the file-like object `tell()` or `write()` methods. Doing so will raise an exception.

`StreamingHttpResponse` should only be used in situations where it is absolutely required that the whole content isn't iterated before transferring the data to the client. Because the content can't be accessed, many middlewares can't function normally. For example the `ETag` and `Content-Length` headers can't be generated for streaming responses.

### Attributes

`StreamingHttpResponse.streaming_content`  
An iterator of strings representing the content.

`StreamingHttpResponse.status_code`  
The **HTTP status code** for the response.

Unless `reason_phrase` is explicitly set, modifying the value of `status_code` outside the constructor will also modify the value of `reason_phrase`.

`StreamingHttpResponse.reason_phrase`

The HTTP reason phrase for the response.

`reason_phrase` no longer defaults to all capital letters. It now uses the [HTTP standard's](#) default reason phrases.

Unless explicitly set, `reason_phrase` is determined by the current value of `status_code`.

`StreamingHttpResponse.streaming`

This is always True.

## 6.16.7 FileResponse objects

**class FileResponse**

*FileResponse* is a subclass of *StreamingHttpResponse* optimized for binary files. It uses `wsgi.file_wrapper` if provided by the wsgi server, otherwise it streams the file out in small chunks.

*FileResponse* expects a file open in binary mode like so:

```
>>> from django.http import FileResponse
>>> response = FileResponse(open('myfile.png', 'rb'))
```

## 6.17 SchemaEditor

**class BaseDatabaseSchemaEditor**

Django's migration system is split into two parts; the logic for calculating and storing what operations should be run (`django.db.migrations`), and the database abstraction layer that turns things like “create a model” or “delete a field” into SQL - which is the job of the *SchemaEditor*.

It's unlikely that you will want to interact directly with *SchemaEditor* as a normal developer using Django, but if you want to write your own migration system, or have more advanced needs, it's a lot nicer than writing SQL.

Each database backend in Django supplies its own version of *SchemaEditor*, and it's always accessible via the `connection.schema_editor()` context manager:

```
with connection.schema_editor() as schema_editor:
    schema_editor.delete_model(MyModel)
```

It must be used via the context manager as this allows it to manage things like transactions and deferred SQL (like creating *ForeignKey* constraints).

It exposes all possible operations as methods, that should be called in the order you wish changes to be applied. Some possible operations or types of change are not possible on all databases - for example, MyISAM does not support foreign key constraints.

If you are writing or maintaining a third-party database backend for Django, you will need to provide a *SchemaEditor* implementation in order to work with 1.7's migration functionality - however, as long as your database is relatively standard in its use of SQL and relational design, you should be able to subclass one of the built-in Django *SchemaEditor* classes and just tweak the syntax a little. Also note that there are a few new database features that migrations will look for: `can_rollback_ddl` and `supports_combined_alters` are the most important.

## 6.17.1 Methods

### `execute()`

`BaseDatabaseSchemaEditor.execute(sql, params=[])`

Executes the SQL statement passed in, with parameters if supplied. This is a simple wrapper around the normal database cursors that allows capture of the SQL to a `.sql` file if the user wishes.

### `create_model()`

`BaseDatabaseSchemaEditor.create_model(model)`

Creates a new table in the database for the provided model, along with any unique constraints or indexes it requires.

### `delete_model()`

`BaseDatabaseSchemaEditor.delete_model(model)`

Drops the model's table in the database along with any unique constraints or indexes it has.

### `alter_unique_together()`

`BaseDatabaseSchemaEditor.alter_unique_together(model, old_unique_together, new_unique_together)`

Changes a model's `unique_together` value; this will add or remove unique constraints from the model's table until they match the new value.

### `alter_index_together()`

`BaseDatabaseSchemaEditor.alter_index_together(model, old_index_together, new_index_together)`

Changes a model's `index_together` value; this will add or remove indexes from the model's table until they match the new value.

### `alter_db_table()`

`BaseDatabaseSchemaEditor.alter_db_table(model, old_db_table, new_db_table)`

Renames the model's table from `old_db_table` to `new_db_table`.

### `alter_db_tablespace()`

`BaseDatabaseSchemaEditor.alter_db_tablespace(model, old_db_tablespace, new_db_tablespace)`

Moves the model's table from one tablespace to another.

### `add_field()`

`BaseDatabaseSchemaEditor.add_field(model, field)`

Adds a column (or sometimes multiple) to the model's table to represent the field. This will also add indexes or a unique constraint if the field has `db_index=True` or `unique=True`.

If the field is a `ManyToManyField` without a value for `through`, instead of creating a column, it will make a table to represent the relationship. If `through` is provided, it is a no-op.

If the field is a `ForeignKey`, this will also add the foreign key constraint to the column.

### `remove_field()`

`BaseDatabaseSchemaEditor.remove_field(model, field)`

Removes the column(s) representing the field from the model's table, along with any unique constraints, foreign key constraints, or indexes caused by that field.

If the field is a `ManyToManyField` without a value for `through`, it will remove the table created to track the relationship. If `through` is provided, it is a no-op.

### `alter_field()`

`BaseDatabaseSchemaEditor.alter_field(model, old_field, new_field, strict=False)`

This transforms the field on the model from the old field to the new one. This includes changing the name of the column (the `db_column` attribute), changing the type of the field (if the field class changes), changing the `NULL` status of the field, adding or removing field-only unique constraints and indexes, changing primary key, and changing the destination of `ForeignKey` constraints.

The most common transformation this cannot do is transforming a `ManyToManyField` into a normal `Field` or vice-versa; Django cannot do this without losing data, and so it will refuse to do it. Instead, `remove_field()` and `add_field()` should be called separately.

If the database has the `supports_combined_alters`, Django will try and do as many of these in a single database call as possible; otherwise, it will issue a separate `ALTER` statement for each change, but will not issue `ALTERs` where no change is required (as South often did).

## 6.17.2 Attributes

All attributes should be considered read-only unless stated otherwise.

### `connection`

`SchemaEditor.connection`

A connection object to the database. A useful attribute of the connection is `alias` which can be used to determine the name of the database being accessed.

This is useful when doing data migrations for *migrations with multiple databases*.

## 6.18 Settings

- *Core Settings*
- *Auth*
- *Messages*
- *Sessions*
- *Sites*
- *Static Files*
- *Core Settings Topical Index*

**Warning:** Be careful when you override settings, especially when the default value is a non-empty list or dictionary, such as `MIDDLEWARE_CLASSES` and `STATICFILES_FINDERS`. Make sure you keep the components required by the features of Django you wish to use.

### 6.18.1 Core Settings

Here's a list of settings available in Django core and their default values. Settings provided by contrib apps are listed below, followed by a topical index of the core settings. For introductory material, see the *settings topic guide*.

#### **ABSOLUTE\_URL\_OVERRIDES**

Default: {} (Empty dictionary)

A dictionary mapping "app\_label.model\_name" strings to functions that take a model object and return its URL. This is a way of inserting or overriding `get_absolute_url()` methods on a per-installation basis. Example:

```
ABSOLUTE_URL_OVERRIDES = {
    'blogs.weblog': lambda o: "/blogs/%s/" % o.slug,
    'news.story': lambda o: "/stories/%s/%s/" % (o.pub_year, o.slug),
}
```

Note that the model name used in this setting should be all lower-case, regardless of the case of the actual model class name.

#### **ADMINS**

Default: [] (Empty list)

A list of all the people who get code error notifications. When `DEBUG=False` and a view raises an exception, Django will email these people with the full exception information. Each item in the list should be a tuple of (Full name, email address). Example:

```
[('John', 'john@example.com'), ('Mary', 'mary@example.com')]
```

Note that Django will email *all* of these people whenever an error happens. See *Error reporting* for more information.

## ALLOWED\_HOSTS

Default: [] (Empty list)

A list of strings representing the host/domain names that this Django site can serve. This is a security measure to prevent *HTTP Host header attacks*, which are possible even under many seemingly-safe web server configurations.

Values in this list can be fully qualified names (e.g. 'www.example.com'), in which case they will be matched against the request's `Host` header exactly (case-insensitive, not including port). A value beginning with a period can be used as a subdomain wildcard: '.example.com' will match `example.com`, `www.example.com`, and any other subdomain of `example.com`. A value of '\*' will match anything; in this case you are responsible to provide your own validation of the `Host` header (perhaps in a middleware; if so this middleware must be listed first in *MIDDLEWARE*).

Django also allows the **fully qualified domain name (FQDN)** of any entries. Some browsers include a trailing dot in the `Host` header which Django strips when performing host validation.

If the `Host` header (or `X-Forwarded-Host` if *USE\_X\_FORWARDED\_HOST* is enabled) does not match any value in this list, the `django.http.HttpRequest.get_host()` method will raise *SuspiciousOperation*.

When *DEBUG* is `True` and *ALLOWED\_HOSTS* is empty, the host is validated against ['localhost', '127.0.0.1', ':::1'].

This validation only applies via `get_host()`; if your code accesses the `Host` header directly from `request.META` you are bypassing this security protection.

In older versions, *ALLOWED\_HOSTS* wasn't checked if *DEBUG=True*. This was also changed in Django 1.9.11 and 1.8.16 to prevent a DNS rebinding attack.

## APPEND\_SLASH

Default: `True`

When set to `True`, if the request URL does not match any of the patterns in the `URLconf` and it doesn't end in a slash, an HTTP redirect is issued to the same URL with a slash appended. Note that the redirect may cause any data submitted in a POST request to be lost.

The *APPEND\_SLASH* setting is only used if *CommonMiddleware* is installed (see *Middleware*). See also *PREPEND\_WWW*.

## CACHES

Default:

```
{
    'default': {
        'BACKEND': 'django.core.cache.backends.locmem.LocMemCache',
    }
}
```

A dictionary containing the settings for all caches to be used with Django. It is a nested dictionary whose contents maps cache aliases to a dictionary containing the options for an individual cache.

The *CACHES* setting must configure a `default` cache; any number of additional caches may also be specified. If you are using a cache backend other than the local memory cache, or you need to define multiple caches, other options will be required. The following cache options are available.

## BACKEND

Default: '' (Empty string)

The cache backend to use. The built-in cache backends are:

- 'django.core.cache.backends.db.DatabaseCache'
- 'django.core.cache.backends.dummy.DummyCache'
- 'django.core.cache.backends.filebased.FileBasedCache'
- 'django.core.cache.backends.locmem.LocMemCache'
- 'django.core.cache.backends.memcached.MemcachedCache'
- 'django.core.cache.backends.memcached.PyLibMCCache'

You can use a cache backend that doesn't ship with Django by setting `BACKEND` to a fully-qualified path of a cache backend class (i.e. `mypackage.backends.whatever.WhateverCache`).

## KEY\_FUNCTION

A string containing a dotted path to a function (or any callable) that defines how to compose a prefix, version and key into a final cache key. The default implementation is equivalent to the function:

```
def make_key(key, key_prefix, version):
    return ':'.join([key_prefix, str(version), key])
```

You may use any key function you want, as long as it has the same argument signature.

See the [cache documentation](#) for more information.

## KEY\_PREFIX

Default: '' (Empty string)

A string that will be automatically included (prepended by default) to all cache keys used by the Django server.

See the [cache documentation](#) for more information.

## LOCATION

Default: '' (Empty string)

The location of the cache to use. This might be the directory for a file system cache, a host and port for a memcache server, or simply an identifying name for a local memory cache. e.g.:

```
CACHES = {
    'default': {
        'BACKEND': 'django.core.cache.backends.filebased.FileBasedCache',
        'LOCATION': '/var/tmp/django_cache',
    }
}
```

## OPTIONS

Default: None

Extra parameters to pass to the cache backend. Available parameters vary depending on your cache backend.

Some information on available parameters can be found in the *cache arguments* documentation. For more information, consult your backend module's own documentation.

## TIMEOUT

Default: 300

The number of seconds before a cache entry is considered stale. If the value of this settings is `None`, cache entries will not expire.

## VERSION

Default: 1

The default version number for cache keys generated by the Django server.

See the *cache documentation* for more information.

## CACHE\_MIDDLEWARE\_ALIAS

Default: `default`

The cache connection to use for the *cache middleware*.

## CACHE\_MIDDLEWARE\_KEY\_PREFIX

Default: `''` (Empty string)

A string which will be prefixed to the cache keys generated by the *cache middleware*. This prefix is combined with the *KEY\_PREFIX* setting; it does not replace it.

See *Django's cache framework*.

## CACHE\_MIDDLEWARE\_SECONDS

Default: 600

The default number of seconds to cache a page for the *cache middleware*.

See *Django's cache framework*.

## CSRF\_COOKIE\_AGE

Default: 31449600 (approximately 1 year, in seconds)

The age of CSRF cookies, in seconds.

The reason for setting a long-lived expiration time is to avoid problems in the case of a user closing a browser or bookmarking a page and then loading that page from a browser cache. Without persistent cookies, the form submission would fail in this case.

Some browsers (specifically Internet Explorer) can disallow the use of persistent cookies or can have the indexes to the cookie jar corrupted on disk, thereby causing CSRF protection checks to (sometimes intermittently) fail. Change this setting to `None` to use session-based CSRF cookies, which keep the cookies in-memory instead of on persistent storage.

#### **CSRF\_COOKIE\_DOMAIN**

Default: `None`

The domain to be used when setting the CSRF cookie. This can be useful for easily allowing cross-subdomain requests to be excluded from the normal cross site request forgery protection. It should be set to a string such as `".example.com"` to allow a POST request from a form on one subdomain to be accepted by a view served from another subdomain.

Please note that the presence of this setting does not imply that Django's CSRF protection is safe from cross-subdomain attacks by default - please see the *CSRF limitations* section.

#### **CSRF\_COOKIE\_HTTPONLY**

Default: `False`

Whether to use `HttpOnly` flag on the CSRF cookie. If this is set to `True`, client-side JavaScript will not be able to access the CSRF cookie.

This can help prevent malicious JavaScript from bypassing CSRF protection. If you enable this and need to send the value of the CSRF token with Ajax requests, your JavaScript will need to pull the value from a hidden CSRF token form input on the page instead of from the cookie.

See `SESSION_COOKIE_HTTPONLY` for details on `HttpOnly`.

#### **CSRF\_COOKIE\_NAME**

Default: `'csrftoken'`

The name of the cookie to use for the CSRF authentication token. This can be whatever you want (as long as it's different from the other cookie names in your application). See *Cross Site Request Forgery protection*.

#### **CSRF\_COOKIE\_PATH**

Default: `'/'`

The path set on the CSRF cookie. This should either match the URL path of your Django installation or be a parent of that path.

This is useful if you have multiple Django instances running under the same hostname. They can use different cookie paths, and each instance will only see its own CSRF cookie.

### CSRF\_COOKIE\_SECURE

Default: `False`

Whether to use a secure cookie for the CSRF cookie. If this is set to `True`, the cookie will be marked as “secure,” which means browsers may ensure that the cookie is only sent with an HTTPS connection.

### CSRF\_FAILURE\_VIEW

Default: `'django.views.csrf.csrf_failure'`

A dotted path to the view function to be used when an incoming request is rejected by the *CSRF protection*. The function should have this signature:

```
def csrf_failure(request, reason=""):
    ...
```

where `reason` is a short message (intended for developers or logging, not for end users) indicating the reason the request was rejected. It should return an *HttpResponseForbidden*.

`django.views.csrf.csrf_failure()` accepts an additional `template_name` parameter that defaults to `'403_csrf.html'`. If a template with that name exists, it will be used to render the page.

The `template_name` parameter and the behavior of searching for a template called `403_csrf.html` were added to `csrf_failure()`.

### CSRF\_HEADER\_NAME

Default: `'HTTP_X_CSRFTOKEN'`

The name of the request header used for CSRF authentication.

As with other HTTP headers in `request.META`, the header name received from the server is normalized by converting all characters to uppercase, replacing any hyphens with underscores, and adding an `'HTTP_'` prefix to the name. For example, if your client sends a `'X-XSRF-TOKEN'` header, the setting should be `'HTTP_X_XSRF_TOKEN'`.

### CSRF\_TRUSTED\_ORIGINS

Default: `[]` (Empty list)

A list of hosts which are trusted origins for unsafe requests (e.g. `POST`). For a *secure* unsafe request, Django’s CSRF protection requires that the request have a `Referer` header that matches the origin present in the `Host` header. This prevents, for example, a `POST` request from `subdomain.example.com` from succeeding against `api.example.com`. If you need cross-origin unsafe requests over HTTPS, continuing the example, add `"subdomain.example.com"` to this list. The setting also supports subdomains, so you could add `".example.com"`, for example, to allow access from all subdomains of `example.com`.

### DATABASES

Default: `{}` (Empty dictionary)

A dictionary containing the settings for all databases to be used with Django. It is a nested dictionary whose contents map a database alias to a dictionary containing the options for an individual database.

The `DATABASES` setting must configure a default database; any number of additional databases may also be specified.

The simplest possible settings file is for a single-database setup using SQLite. This can be configured using the following:

```
DATABASES = {
    'default': {
        'ENGINE': 'django.db.backends.sqlite3',
        'NAME': 'mydatabase',
    }
}
```

When connecting to other database backends, such as MySQL, Oracle, or PostgreSQL, additional connection parameters will be required. See the `ENGINE` setting below on how to specify other database types. This example is for PostgreSQL:

```
DATABASES = {
    'default': {
        'ENGINE': 'django.db.backends.postgresql',
        'NAME': 'mydatabase',
        'USER': 'mydatabaseuser',
        'PASSWORD': 'mypassword',
        'HOST': '127.0.0.1',
        'PORT': '5432',
    }
}
```

The following inner options that may be required for more complex configurations are available:

#### **ATOMIC\_REQUESTS**

Default: `False`

Set this to `True` to wrap each view in a transaction on this database. See *Tying transactions to HTTP requests*.

#### **AUTOCOMMIT**

Default: `True`

Set this to `False` if you want to *disable Django's transaction management* and implement your own.

#### **ENGINE**

Default: `''` (Empty string)

The database backend to use. The built-in database backends are:

- `'django.db.backends.postgresql'`
- `'django.db.backends.mysql'`
- `'django.db.backends.sqlite3'`
- `'django.db.backends.oracle'`

You can use a database backend that doesn't ship with Django by setting `ENGINE` to a fully-qualified path (i.e. `mypackage.backends.whatever`).

The `django.db.backends.postgresql` backend is named `django.db.backends.postgresql_psycopg2` in older releases. For backwards compatibility, the old name still works in newer versions.

## HOST

Default: '' (Empty string)

Which host to use when connecting to the database. An empty string means localhost. Not used with SQLite.

If this value starts with a forward slash ('/') and you're using MySQL, MySQL will connect via a Unix socket to the specified socket. For example:

```
"HOST": '/var/run/mysql'
```

If you're using MySQL and this value *doesn't* start with a forward slash, then this value is assumed to be the host.

If you're using PostgreSQL, by default (empty `HOST`), the connection to the database is done through UNIX domain sockets ('local' lines in `pg_hba.conf`). If your UNIX domain socket is not in the standard location, use the same value of `unix_socket_directory` from `postgresql.conf`. If you want to connect through TCP sockets, set `HOST` to 'localhost' or '127.0.0.1' ('host' lines in `pg_hba.conf`). On Windows, you should always define `HOST`, as UNIX domain sockets are not available.

## NAME

Default: '' (Empty string)

The name of the database to use. For SQLite, it's the full path to the database file. When specifying the path, always use forward slashes, even on Windows (e.g. `C:/homes/user/mysite/sqlite3.db`).

## CONN\_MAX\_AGE

Default: 0

The lifetime of a database connection, in seconds. Use 0 to close database connections at the end of each request — Django's historical behavior — and `None` for unlimited persistent connections.

## OPTIONS

Default: {} (Empty dictionary)

Extra parameters to use when connecting to the database. Available parameters vary depending on your database backend.

Some information on available parameters can be found in the *Database Backends* documentation. For more information, consult your backend module's own documentation.

## PASSWORD

Default: '' (Empty string)

The password to use when connecting to the database. Not used with SQLite.

**PORT**

Default: '' (Empty string)

The port to use when connecting to the database. An empty string means the default port. Not used with SQLite.

**TIME\_ZONE**

Default: None

A string representing the time zone for datetimes stored in this database (assuming that it doesn't support time zones) or None. The same values are accepted as in the general `TIME_ZONE` setting.

This allows interacting with third-party databases that store datetimes in local time rather than UTC. To avoid issues around DST changes, you shouldn't set this option for databases managed by Django.

Setting this option requires installing `pytz`.

When `USE_TZ` is `True` and the database doesn't support time zones (e.g. SQLite, MySQL, Oracle), Django reads and writes datetimes in local time according to this option if it is set and in UTC if it isn't.

When `USE_TZ` is `True` and the database supports time zones (e.g. PostgreSQL), it is an error to set this option.

Before Django 1.9, the PostgreSQL database backend accepted an undocumented `TIME_ZONE` option, which caused data corruption.

When `USE_TZ` is `False`, it is an error to set this option.

**USER**

Default: '' (Empty string)

The username to use when connecting to the database. Not used with SQLite.

**TEST**

Default: {} (Empty dictionary)

A dictionary of settings for test databases; for more details about the creation and use of test databases, see *The test database*.

Here's an example with a test database configuration:

```
DATABASES = {
    'default': {
        'ENGINE': 'django.db.backends.postgresql',
        'USER': 'mydatabaseuser',
        'NAME': 'mydatabase',
        'TEST': {
            'NAME': 'mytestdatabase',
        },
    },
}
```

The following keys in the `TEST` dictionary are available:

## CHARSET

Default: None

The character set encoding used to create the test database. The value of this string is passed directly through to the database, so its format is backend-specific.

Supported by the [PostgreSQL](#) (`postgresql`) and [MySQL](#) (`mysql`) backends.

## COLLATION

Default: None

The collation order to use when creating the test database. This value is passed directly to the backend, so its format is backend-specific.

Only supported for the `mysql` backend (see the [MySQL manual](#) for details).

## DEPENDENCIES

Default: `['default']`, for all databases other than `default`, which has no dependencies.

The creation-order dependencies of the database. See the documentation on *controlling the creation order of test databases* for details.

## MIRROR

Default: None

The alias of the database that this database should mirror during testing.

This setting exists to allow for testing of primary/replica (referred to as master/slave by some databases) configurations of multiple databases. See the documentation on *testing primary/replica configurations* for details.

## NAME

Default: None

The name of database to use when running the test suite.

If the default value (`None`) is used with the SQLite database engine, the tests will use a memory resident database. For all other database engines the test database will use the name `'test_' + DATABASE_NAME`.

See *The test database*.

## SERIALIZE

Boolean value to control whether or not the default test runner serializes the database into an in-memory JSON string before running tests (used to restore the database state between tests if you don't have transactions). You can set this to `False` to speed up creation time if you don't have any test classes with *serialized\_rollback=True*.

### **CREATE\_DB**

Default: True

This is an Oracle-specific setting.

If it is set to `False`, the test tablespaces won't be automatically created at the beginning of the tests or dropped at the end.

### **CREATE\_USER**

Default: True

This is an Oracle-specific setting.

If it is set to `False`, the test user won't be automatically created at the beginning of the tests and dropped at the end.

### **USER**

Default: None

This is an Oracle-specific setting.

The username to use when connecting to the Oracle database that will be used when running tests. If not provided, Django will use `'test_' + USER`.

### **PASSWORD**

Default: None

This is an Oracle-specific setting.

The password to use when connecting to the Oracle database that will be used when running tests. If not provided, Django will generate a random password.

Older versions used a hardcoded default password. This was also changed in 1.9.11 and 1.8.16 to fix possible security implications.

### **TBLSPACE**

Default: None

This is an Oracle-specific setting.

The name of the tablespace that will be used when running tests. If not provided, Django will use `'test_' + USER`.

### **TBLSPACE\_TMP**

Default: None

This is an Oracle-specific setting.

The name of the temporary tablespace that will be used when running tests. If not provided, Django will use `'test_' + USER + '_temp'`.

**DATAFILE**

Default: None

This is an Oracle-specific setting.

The name of the datafile to use for the TBLSPACE. If not provided, Django will use `TBLSPACE + '.dbf'`.

**DATAFILE\_TMP**

Default: None

This is an Oracle-specific setting.

The name of the datafile to use for the TBLSPACE\_TMP. If not provided, Django will use `TBLSPACE_TMP + '.dbf'`.

**DATAFILE\_MAXSIZE**

Default: '500M'

This is an Oracle-specific setting.

The maximum size that the DATAFILE is allowed to grow to.

**DATAFILE\_TMP\_MAXSIZE**

Default: '500M'

This is an Oracle-specific setting.

The maximum size that the DATAFILE\_TMP is allowed to grow to.

**DATA\_UPLOAD\_MAX\_MEMORY\_SIZE**

Default: 2621440 (i.e. 2.5 MB).

The maximum size in bytes that a request body may be before a *SuspiciousOperation* (`RequestDataTooBig`) is raised. The check is done when accessing `request.body` or `request.POST` and is calculated against the total request size excluding any file upload data. You can set this to `None` to disable the check. Applications that are expected to receive unusually large form posts should tune this setting.

The amount of request data is correlated to the amount of memory needed to process the request and populate the GET and POST dictionaries. Large requests could be used as a denial-of-service attack vector if left unchecked. Since web servers don't typically perform deep request inspection, it's not possible to perform a similar check at that level.

See also *FILE\_UPLOAD\_MAX\_MEMORY\_SIZE*.

**DATA\_UPLOAD\_MAX\_NUMBER\_FIELDS**

Default: 1000

The maximum number of parameters that may be received via GET or POST before a *SuspiciousOperation* (`TooManyFields`) is raised. You can set this to `None` to disable the check. Applications that are expected to receive an unusually large number of form fields should tune this setting.

The number of request parameters is correlated to the amount of time needed to process the request and populate the GET and POST dictionaries. Large requests could be used as a denial-of-service attack vector if left unchecked. Since web servers don't typically perform deep request inspection, it's not possible to perform a similar check at that level.

#### DATABASE\_ROUTERS

Default: [] (Empty list)

The list of routers that will be used to determine which database to use when performing a database query.

See the documentation on *automatic database routing in multi database configurations*.

#### DATE\_FORMAT

Default: 'N j, Y' (e.g. Feb. 4, 2003)

The default formatting to use for displaying date fields in any part of the system. Note that if `USE_L10N` is set to `True`, then the locale-dictated format has higher precedence and will be applied instead. See *allowed date format strings*.

See also `DATETIME_FORMAT`, `TIME_FORMAT` and `SHORT_DATE_FORMAT`.

#### DATE\_INPUT\_FORMATS

Default:

```
[
    '%Y-%m-%d', '%m/%d/%Y', '%m/%d/%y', # '2006-10-25', '10/25/2006', '10/25/06'
    '%b %d %Y', '%b %d, %Y',           # 'Oct 25 2006', 'Oct 25, 2006'
    '%d %b %Y', '%d %b, %Y',           # '25 Oct 2006', '25 Oct, 2006'
    '%B %d %Y', '%B %d, %Y',           # 'October 25 2006', 'October 25, 2006'
    '%d %B %Y', '%d %B, %Y',           # '25 October 2006', '25 October, 2006'
]
```

A list of formats that will be accepted when inputting data on a date field. Formats will be tried in order, using the first valid one. Note that these format strings use Python's `datetime` module syntax, not the format strings from the `date` template filter.

When `USE_L10N` is `True`, the locale-dictated format has higher precedence and will be applied instead.

See also `DATETIME_INPUT_FORMATS` and `TIME_INPUT_FORMATS`.

#### DATETIME\_FORMAT

Default: 'N j, Y, P' (e.g. Feb. 4, 2003, 4 p.m.)

The default formatting to use for displaying datetime fields in any part of the system. Note that if `USE_L10N` is set to `True`, then the locale-dictated format has higher precedence and will be applied instead. See *allowed date format strings*.

See also `DATE_FORMAT`, `TIME_FORMAT` and `SHORT_DATETIME_FORMAT`.

## DATETIME\_INPUT\_FORMATS

Default:

```
[
    '%Y-%m-%d %H:%M:%S',      # '2006-10-25 14:30:59'
    '%Y-%m-%d %H:%M:%S.%F',  # '2006-10-25 14:30:59.000200'
    '%Y-%m-%d %H:%M',        # '2006-10-25 14:30'
    '%Y-%m-%d',              # '2006-10-25'
    '%m/%d/%Y %H:%M:%S',     # '10/25/2006 14:30:59'
    '%m/%d/%Y %H:%M:%S.%F',  # '10/25/2006 14:30:59.000200'
    '%m/%d/%Y %H:%M',        # '10/25/2006 14:30'
    '%m/%d/%Y',              # '10/25/2006'
    '%m/%d/%y %H:%M:%S',     # '10/25/06 14:30:59'
    '%m/%d/%y %H:%M:%S.%F',  # '10/25/06 14:30:59.000200'
    '%m/%d/%y %H:%M',        # '10/25/06 14:30'
    '%m/%d/%y',              # '10/25/06'
]
```

A list of formats that will be accepted when inputting data on a datetime field. Formats will be tried in order, using the first valid one. Note that these format strings use Python's `datetime` module syntax, not the format strings from the `date` template filter.

When `USE_L10N` is `True`, the locale-dictated format has higher precedence and will be applied instead.

See also `DATE_INPUT_FORMATS` and `TIME_INPUT_FORMATS`.

## DEBUG

Default: `False`

A boolean that turns on/off debug mode.

Never deploy a site into production with `DEBUG` turned on.

Did you catch that? NEVER deploy a site into production with `DEBUG` turned on.

One of the main features of debug mode is the display of detailed error pages. If your app raises an exception when `DEBUG` is `True`, Django will display a detailed traceback, including a lot of metadata about your environment, such as all the currently defined Django settings (from `settings.py`).

As a security measure, Django will *not* include settings that might be sensitive, such as `SECRET_KEY`. Specifically, it will exclude any setting whose name includes any of the following:

- 'API'
- 'KEY'
- 'PASS'
- 'SECRET'
- 'SIGNATURE'
- 'TOKEN'

Note that these are *partial* matches. 'PASS' will also match PASSWORD, just as 'TOKEN' will also match TOKENIZED and so on.

Still, note that there are always going to be sections of your debug output that are inappropriate for public consumption. File paths, configuration options and the like all give attackers extra information about your server.

It is also important to remember that when running with `DEBUG` turned on, Django will remember every SQL query it executes. This is useful when you're debugging, but it'll rapidly consume memory on a production server.

Finally, if `DEBUG` is `False`, you also need to properly set the `ALLOWED_HOSTS` setting. Failing to do so will result in all requests being returned as “Bad Request (400)”.

---

**Note:** The default `settings.py` file created by `django-admin startproject` sets `DEBUG = True` for convenience.

---

#### `DEBUG_PROPAGATE_EXCEPTIONS`

Default: `False`

If set to `True`, Django's normal exception handling of view functions will be suppressed, and exceptions will propagate upwards. This can be useful for some test setups, and should never be used on a live site.

#### `DECIMAL_SEPARATOR`

Default: `'.'` (Dot)

Default decimal separator used when formatting decimal numbers.

Note that if `USE_L10N` is set to `True`, then the locale-dictated format has higher precedence and will be applied instead.

See also `NUMBER_GROUPING`, `THOUSAND_SEPARATOR` and `USE_THOUSAND_SEPARATOR`.

#### `DEFAULT_CHARSET`

Default: `'utf-8'`

Default charset to use for all `HttpResponse` objects, if a MIME type isn't manually specified. Used with `DEFAULT_CONTENT_TYPE` to construct the `Content-Type` header.

#### `DEFAULT_CONTENT_TYPE`

Default: `'text/html'`

Default content type to use for all `HttpResponse` objects, if a MIME type isn't manually specified. Used with `DEFAULT_CHARSET` to construct the `Content-Type` header.

#### `DEFAULT_EXCEPTION_REPORTER_FILTER`

Default: `'django.views.debug.SafeExceptionReporterFilter'`

Default exception reporter filter class to be used if none has been assigned to the `HttpRequest` instance yet. See *Filtering error reports*.

#### **DEFAULT\_FILE\_STORAGE**

Default: `'django.core.files.storage.FileSystemStorage'`

Default file storage class to be used for any file-related operations that don't specify a particular storage system. See *Managing files*.

#### **DEFAULT\_FROM\_EMAIL**

Default: `'webmaster@localhost'`

Default email address to use for various automated correspondence from the site manager(s). This doesn't include error messages sent to *ADMINS* and *MANAGERS*; for that, see *SERVER\_EMAIL*.

#### **DEFAULT\_INDEX\_TABLESPACE**

Default: `''` (Empty string)

Default tablespace to use for indexes on fields that don't specify one, if the backend supports it (see *Tablespaces*).

#### **DEFAULT\_TABLESPACE**

Default: `''` (Empty string)

Default tablespace to use for models that don't specify one, if the backend supports it (see *Tablespaces*).

#### **DISALLOWED\_USER\_AGENTS**

Default: `[]` (Empty list)

List of compiled regular expression objects representing User-Agent strings that are not allowed to visit any page, systemwide. Use this for bad robots/crawlers. This is only used if `CommonMiddleware` is installed (see *Middleware*).

#### **EMAIL\_BACKEND**

Default: `'django.core.mail.backends.smtp.EmailBackend'`

The backend to use for sending emails. For the list of available backends see *Sending email*.

#### **EMAIL\_FILE\_PATH**

Default: Not defined

The directory used by the `file` email backend to store output files.

#### **EMAIL\_HOST**

Default: `'localhost'`

The host to use for sending email.

See also *EMAIL\_PORT*.

#### **EMAIL\_HOST\_PASSWORD**

Default: '' (Empty string)

Password to use for the SMTP server defined in `EMAIL_HOST`. This setting is used in conjunction with `EMAIL_HOST_USER` when authenticating to the SMTP server. If either of these settings is empty, Django won't attempt authentication.

See also `EMAIL_HOST_USER`.

#### **EMAIL\_HOST\_USER**

Default: '' (Empty string)

Username to use for the SMTP server defined in `EMAIL_HOST`. If empty, Django won't attempt authentication.

See also `EMAIL_HOST_PASSWORD`.

#### **EMAIL\_PORT**

Default: 25

Port to use for the SMTP server defined in `EMAIL_HOST`.

#### **EMAIL\_SUBJECT\_PREFIX**

Default: '[Django] '

Subject-line prefix for email messages sent with `django.core.mail.mail_admins` or `django.core.mail.mail_managers`. You'll probably want to include the trailing space.

#### **EMAIL\_USE\_TLS**

Default: False

Whether to use a TLS (secure) connection when talking to the SMTP server. This is used for explicit TLS connections, generally on port 587. If you are experiencing hanging connections, see the implicit TLS setting `EMAIL_USE_SSL`.

#### **EMAIL\_USE\_SSL**

Default: False

Whether to use an implicit TLS (secure) connection when talking to the SMTP server. In most email documentation this type of TLS connection is referred to as SSL. It is generally used on port 465. If you are experiencing problems, see the explicit TLS setting `EMAIL_USE_TLS`.

Note that `EMAIL_USE_TLS`/`EMAIL_USE_SSL` are mutually exclusive, so only set one of those settings to True.

#### **EMAIL\_SSL\_CERTFILE**

Default: None

If `EMAIL_USE_SSL` or `EMAIL_USE_TLS` is True, you can optionally specify the path to a PEM-formatted certificate chain file to use for the SSL connection.

**EMAIL\_SSL\_KEYFILE**

Default: None

If `EMAIL_USE_SSL` or `EMAIL_USE_TLS` is `True`, you can optionally specify the path to a PEM-formatted private key file to use for the SSL connection.

Note that setting `EMAIL_SSL_CERTFILE` and `EMAIL_SSL_KEYFILE` doesn't result in any certificate checking. They're passed to the underlying SSL connection. Please refer to the documentation of Python's `ssl.wrap_socket()` function for details on how the certificate chain file and private key file are handled.

**EMAIL\_TIMEOUT**

Default: None

Specifies a timeout in seconds for blocking operations like the connection attempt.

**FILE\_CHARSET**

Default: `'utf-8'`

The character encoding used to decode any files read from disk. This includes template files and initial SQL data files.

**FILE\_UPLOAD\_HANDLERS**

Default:

```
[
    'django.core.files.uploadhandler.MemoryFileUploadHandler',
    'django.core.files.uploadhandler.TemporaryFileUploadHandler',
]
```

A list of handlers to use for uploading. Changing this setting allows complete customization – even replacement – of Django's upload process.

See *Managing files* for details.

**FILE\_UPLOAD\_MAX\_MEMORY\_SIZE**

Default: 2621440 (i.e. 2.5 MB).

The maximum size (in bytes) that an upload will be before it gets streamed to the file system. See *Managing files* for details.

See also `DATA_UPLOAD_MAX_MEMORY_SIZE`.

**FILE\_UPLOAD\_DIRECTORY\_PERMISSIONS**

Default: None

The numeric mode to apply to directories created in the process of uploading files.

This setting also determines the default permissions for collected static directories when using the `collectstatic` management command. See `collectstatic` for details on overriding it.

This value mirrors the functionality and caveats of the `FILE_UPLOAD_PERMISSIONS` setting.

#### `FILE_UPLOAD_PERMISSIONS`

Default: `None`

The numeric mode (i.e. `0o644`) to set newly uploaded files to. For more information about what these modes mean, see the documentation for `os.chmod()`.

If this isn't given or is `None`, you'll get operating-system dependent behavior. On most platforms, temporary files will have a mode of `0o600`, and files saved from memory will be saved using the system's standard `umask`.

For security reasons, these permissions aren't applied to the temporary files that are stored in `FILE_UPLOAD_TEMP_DIR`.

This setting also determines the default permissions for collected static files when using the `collectstatic` management command. See `collectstatic` for details on overriding it.

**Warning:** Always prefix the mode with a 0.

If you're not familiar with file modes, please note that the leading 0 is very important: it indicates an octal number, which is the way that modes must be specified. If you try to use `644`, you'll get totally incorrect behavior.

#### `FILE_UPLOAD_TEMP_DIR`

Default: `None`

The directory to store data to (typically files larger than `FILE_UPLOAD_MAX_MEMORY_SIZE`) temporarily while uploading files. If `None`, Django will use the standard temporary directory for the operating system. For example, this will default to `/tmp` on \*nix-style operating systems.

See *Managing files* for details.

#### `FIRST_DAY_OF_WEEK`

Default: `0` (Sunday)

A number representing the first day of the week. This is especially useful when displaying a calendar. This value is only used when not using format internationalization, or when a format cannot be found for the current locale.

The value must be an integer from 0 to 6, where 0 means Sunday, 1 means Monday and so on.

#### `FIXTURE_DIRS`

Default: `[]` (Empty list)

List of directories searched for fixture files, in addition to the `fixtures` directory of each application, in search order.

Note that these paths should use Unix-style forward slashes, even on Windows.

See *Providing initial data with fixtures* and *Fixture loading*.

### FORCE\_SCRIPT\_NAME

Default: None

If not None, this will be used as the value of the `SCRIPT_NAME` environment variable in any HTTP request. This setting can be used to override the server-provided value of `SCRIPT_NAME`, which may be a rewritten version of the preferred value or not supplied at all. It is also used by `django.setup()` to set the URL resolver script prefix outside of the request/response cycle (e.g. in management commands and standalone scripts) to generate correct URLs when `SCRIPT_NAME` is not `/`.

The setting's use in `django.setup()` was added.

### FORMAT\_MODULE\_PATH

Default: None

A full Python path to a Python package that contains format definitions for project locales. If not None, Django will check for a `formats.py` file, under the directory named as the current locale, and will use the formats defined in this file.

For example, if `FORMAT_MODULE_PATH` is set to `mysite.formats`, and current language is `en` (English), Django will expect a directory tree like:

```
mysite/
  formats/
    __init__.py
    en/
      __init__.py
      formats.py
```

You can also set this setting to a list of Python paths, for example:

```
FORMAT_MODULE_PATH = [
    'mysite.formats',
    'some_app.formats',
]
```

When Django searches for a certain format, it will go through all given Python paths until it finds a module that actually defines the given format. This means that formats defined in packages farther up in the list will take precedence over the same formats in packages farther down.

Available formats are `DATE_FORMAT`, `TIME_FORMAT`, `DATETIME_FORMAT`, `YEAR_MONTH_FORMAT`, `MONTH_DAY_FORMAT`, `SHORT_DATE_FORMAT`, `SHORT_DATETIME_FORMAT`, `FIRST_DAY_OF_WEEK`, `DECIMAL_SEPARATOR`, `THOUSAND_SEPARATOR` and `NUMBER_GROUPING`.

### IGNORABLE\_404\_URLS

Default: [] (Empty list)

List of compiled regular expression objects describing URLs that should be ignored when reporting HTTP 404 errors via email (see [Error reporting](#)). Regular expressions are matched against *request's full paths* (including query string, if any). Use this if your site does not provide a commonly requested file such as `favicon.ico` or `robots.txt`, or if it gets hammered by script kiddies.

This is only used if `BrokenLinkEmailsMiddleware` is enabled (see [Middleware](#)).

## INSTALLED\_APPS

Default: [] (Empty list)

A list of strings designating all applications that are enabled in this Django installation. Each string should be a dotted Python path to:

- an application configuration class (preferred), or
- a package containing an application.

*Learn more about application configurations.*

---

### Use the application registry for introspection

Your code should never access `INSTALLED_APPS` directly. Use `django.apps.apps` instead.

---

### Application names and labels must be unique in INSTALLED\_APPS

Application *names* — the dotted Python path to the application package — must be unique. There is no way to include the same application twice, short of duplicating its code under another name.

Application *labels* — by default the final part of the name — must be unique too. For example, you can't include both `django.contrib.auth` and `myproject.auth`. However, you can relabel an application with a custom configuration that defines a different *label*.

These rules apply regardless of whether `INSTALLED_APPS` references application configuration classes or application packages.

---

When several applications provide different versions of the same resource (template, static file, management command, translation), the application listed first in `INSTALLED_APPS` has precedence.

## INTERNAL\_IPS

Default: [] (Empty list)

A list of IP addresses, as strings, that:

- Allow the `debug()` context processor to add some variables to the template context.
- Can use the *admin docs bookmarklets* even if not logged in as a staff user.
- Are marked as “internal” (as opposed to “EXTERNAL”) in `AdminEmailHandler` emails.

## LANGUAGE\_CODE

Default: 'en-us'

A string representing the language code for this installation. This should be in standard *language ID format*. For example, U.S. English is "en-us". See also the [list of language identifiers](#) and *Internationalization and localization*.

`USE_I18N` must be active for this setting to have any effect.

It serves two purposes:

- If the locale middleware isn't in use, it decides which translation is served to all users.

- If the locale middleware is active, it provides a fallback language in case the user's preferred language can't be determined or is not supported by the website. It also provides the fallback translation when a translation for a given literal doesn't exist for the user's preferred language.

See *How Django discovers language preference* for more details.

#### **LANGUAGE\_COOKIE\_AGE**

Default: None (expires at browser close)

The age of the language cookie, in seconds.

#### **LANGUAGE\_COOKIE\_DOMAIN**

Default: None

The domain to use for the language cookie. Set this to a string such as `".example.com"` (note the leading dot!) for cross-domain cookies, or use `None` for a standard domain cookie.

Be cautious when updating this setting on a production site. If you update this setting to enable cross-domain cookies on a site that previously used standard domain cookies, existing user cookies that have the old domain will not be updated. This will result in site users being unable to switch the language as long as these cookies persist. The only safe and reliable option to perform the switch is to change the language cookie name permanently (via the `LANGUAGE_COOKIE_NAME` setting) and to add a middleware that copies the value from the old cookie to a new one and then deletes the old one.

#### **LANGUAGE\_COOKIE\_NAME**

Default: `'django_language'`

The name of the cookie to use for the language cookie. This can be whatever you want (as long as it's different from the other cookie names in your application). See *Internationalization and localization*.

#### **LANGUAGE\_COOKIE\_PATH**

Default: `'/'`

The path set on the language cookie. This should either match the URL path of your Django installation or be a parent of that path.

This is useful if you have multiple Django instances running under the same hostname. They can use different cookie paths and each instance will only see its own language cookie.

Be cautious when updating this setting on a production site. If you update this setting to use a deeper path than it previously used, existing user cookies that have the old path will not be updated. This will result in site users being unable to switch the language as long as these cookies persist. The only safe and reliable option to perform the switch is to change the language cookie name permanently (via the `LANGUAGE_COOKIE_NAME` setting), and to add a middleware that copies the value from the old cookie to a new one and then deletes the one.

#### **LANGUAGES**

Default: A list of all available languages. This list is continually growing and including a copy here would inevitably become rapidly out of date. You can see the current list of translated languages by looking in `django/conf/global_settings.py` (or view the [online source](#)).

The list is a list of two-tuples in the format (*language code*, language name) – for example, ('ja', 'Japanese'). This specifies which languages are available for language selection. See *Internationalization and localization*.

Generally, the default value should suffice. Only set this setting if you want to restrict language selection to a subset of the Django-provided languages.

If you define a custom `LANGUAGES` setting, you can mark the language names as translation strings using the `ugettext_lazy()` function.

Here's a sample settings file:

```
from django.utils.translation import ugettext_lazy as _

LANGUAGES = [
    ('de', _('German')),
    ('en', _('English')),
]
```

## LOCALE\_PATHS

Default: [] (Empty list)

A list of directories where Django looks for translation files. See *How Django discovers translations*.

Example:

```
LOCALE_PATHS = [
    '/home/www/project/common_files/locale',
    '/var/local/translations/locale',
]
```

Django will look within each of these paths for the `<locale_code>/LC_MESSAGES` directories containing the actual translation files.

## LOGGING

Default: A logging configuration dictionary.

A data structure containing configuration information. The contents of this data structure will be passed as the argument to the configuration method described in *LOGGING\_CONFIG*.

Among other things, the default logging configuration passes HTTP 500 server errors to an email log handler when `DEBUG` is `False`. See also *Configuring logging*.

You can see the default logging configuration by looking in `django/utils/log.py` (or view the [online source](#)).

## LOGGING\_CONFIG

Default: 'logging.config.dictConfig'

A path to a callable that will be used to configure logging in the Django project. Points at a instance of Python's `dictConfig` configuration method by default.

If you set `LOGGING_CONFIG` to `None`, the logging configuration process will be skipped.

## MANAGERS

Default: [] (Empty list)

A list in the same format as `ADMINS` that specifies who should get broken link notifications when `BrokenLinkEmailsMiddleware` is enabled.

## MEDIA\_ROOT

Default: '' (Empty string)

Absolute filesystem path to the directory that will hold *user-uploaded files*.

Example: `"/var/www/example.com/media/"`

See also `MEDIA_URL`.

**Warning:** `MEDIA_ROOT` and `STATIC_ROOT` must have different values. Before `STATIC_ROOT` was introduced, it was common to rely or fallback on `MEDIA_ROOT` to also serve static files; however, since this can have serious security implications, there is a validation check to prevent it.

## MEDIA\_URL

Default: '' (Empty string)

URL that handles the media served from `MEDIA_ROOT`, used for *managing stored files*. It must end in a slash if set to a non-empty value. You will need to *configure these files to be served* in both development and production environments.

If you want to use `{{ MEDIA_URL }}` in your templates, add `'django.template.context_processors.media'` in the `'context_processors'` option of `TEMPLATES`.

Example: `"http://media.example.com/"`

**Warning:** There are security risks if you are accepting uploaded content from untrusted users! See the security guide's topic on *User-uploaded content* for mitigation details.

**Warning:** `MEDIA_URL` and `STATIC_URL` must have different values. See `MEDIA_ROOT` for more details.

## MIDDLEWARE

Default: None

A list of middleware to use. See *Middleware*.

## MIDDLEWARE\_CLASSES

Deprecated since version 1.10: Old-style middleware that uses `settings.MIDDLEWARE_CLASSES` are deprecated. *Adapt old, custom middleware* and use the `MIDDLEWARE` setting.

Default:

```
[
    'django.middleware.common.CommonMiddleware',
    'django.middleware.csrf.CsrfViewMiddleware',
]
```

A list of middleware classes to use. This was the default setting used in Django 1.9 and earlier. Django 1.10 introduced a new style of middleware. If you have an older project using this setting you should *update any middleware you've written yourself* to the new style and then use the `MIDDLEWARE` setting.

### MIGRATION\_MODULES

Default: {} (Empty dictionary)

A dictionary specifying the package where migration modules can be found on a per-app basis. The default value of this setting is an empty dictionary, but the default package name for migration modules is `migrations`.

Example:

```
{'blog': 'blog.db_migrations'}
```

In this case, migrations pertaining to the `blog` app will be contained in the `blog.db_migrations` package.

If you provide the `app_label` argument, `makemigrations` will automatically create the package if it doesn't already exist.

When you supply `None` as a value for an app, Django will consider the app as an app without migrations regardless of an existing `migrations` submodule. This can be used, for example, in a test settings file to skip migrations while testing (tables will still be created for the apps' models). If this is used in your general project settings, remember to use the `migrate --run-syncdb` option if you want to create tables for the app.

### MONTH\_DAY\_FORMAT

Default: 'F j'

The default formatting to use for date fields on Django admin change-list pages – and, possibly, by other parts of the system – in cases when only the month and day are displayed.

For example, when a Django admin change-list page is being filtered by a date drilldown, the header for a given day displays the day and month. Different locales have different formats. For example, U.S. English would say “January 1,” whereas Spanish might say “1 Enero.”

Note that if `USE_L10N` is set to `True`, then the corresponding locale-dictated format has higher precedence and will be applied.

See *allowed date format strings*. See also `DATE_FORMAT`, `DATETIME_FORMAT`, `TIME_FORMAT` and `YEAR_MONTH_FORMAT`.

### NUMBER\_GROUPING

Default: 0

Number of digits grouped together on the integer part of a number.

Common use is to display a thousand separator. If this setting is 0, then no grouping will be applied to the number. If this setting is greater than 0, then `THOUSAND_SEPARATOR` will be used as the separator between those groups.

Note that if `USE_L10N` is set to `True`, then the locale-dictated format has higher precedence and will be applied instead.

See also `DECIMAL_SEPARATOR`, `THOUSAND_SEPARATOR` and `USE_THOUSAND_SEPARATOR`.

#### `PREPEND_WWW`

Default: `False`

Whether to prepend the “www.” subdomain to URLs that don’t have it. This is only used if `CommonMiddleware` is installed (see *Middleware*). See also `APPEND_SLASH`.

#### `ROOT_URLCONF`

Default: Not defined

A string representing the full Python import path to your root URLconf. For example: `"mydjangoapps.urls"`. Can be overridden on a per-request basis by setting the attribute `urlconf` on the incoming `HttpRequest` object. See *How Django processes a request* for details.

#### `SECRET_KEY`

Default: `''` (Empty string)

A secret key for a particular Django installation. This is used to provide *cryptographic signing*, and should be set to a unique, unpredictable value.

`django-admin startproject` automatically adds a randomly-generated `SECRET_KEY` to each new project.

Uses of the key shouldn’t assume that it’s text or bytes. Every use should go through `force_text()` or `force_bytes()` to convert it to the desired type.

Django will refuse to start if `SECRET_KEY` is not set.

**Warning: Keep this value secret.**

Running Django with a known `SECRET_KEY` defeats many of Django’s security protections, and can lead to privilege escalation and remote code execution vulnerabilities.

The secret key is used for:

- All *sessions* if you are using any other session backend than `django.contrib.sessions.backends.cache`, or are using the default `get_session_auth_hash()`.
- All *messages* if you are using `CookieStorage` or `FallbackStorage`.
- All `password_reset()` tokens.
- Any usage of *cryptographic signing*, unless a different key is provided.

If you rotate your secret key, all of the above will be invalidated. Secret keys are not used for passwords of users and key rotation will not affect them.

---

**Note:** The default `settings.py` file created by `django-admin startproject` creates a unique `SECRET_KEY` for convenience.

---

#### `SECURE_BROWSER_XSS_FILTER`

Default: `False`

If `True`, the `SecurityMiddleware` sets the `X-XSS-Protection: 1; mode=block` header on all responses that do not already have it.

#### `SECURE_CONTENT_TYPE_NOSNIFF`

Default: `False`

If `True`, the `SecurityMiddleware` sets the `X-Content-Type-Options: nosniff` header on all responses that do not already have it.

#### `SECURE_HSTS_INCLUDE_SUBDOMAINS`

Default: `False`

If `True`, the `SecurityMiddleware` adds the `includeSubDomains` directive to the `HTTP Strict Transport Security` header. It has no effect unless `SECURE_HSTS_SECONDS` is set to a non-zero value.

**Warning:** Setting this incorrectly can irreversibly (for the value of `SECURE_HSTS_SECONDS`) break your site. Read the `HTTP Strict Transport Security` documentation first.

#### `SECURE_HSTS_SECONDS`

Default: `0`

If set to a non-zero integer value, the `SecurityMiddleware` sets the `HTTP Strict Transport Security` header on all responses that do not already have it.

**Warning:** Setting this incorrectly can irreversibly (for some time) break your site. Read the `HTTP Strict Transport Security` documentation first.

#### `SECURE_PROXY_SSL_HEADER`

Default: `None`

A tuple representing a HTTP header/value combination that signifies a request is secure. This controls the behavior of the request object's `is_secure()` method.

This takes some explanation. By default, `is_secure()` is able to determine whether a request is secure by looking at whether the requested URL uses “`https://`”. This is important for Django’s CSRF protection, and may be used by your own code or third-party apps.

If your Django app is behind a proxy, though, the proxy may be “swallowing” the fact that a request is HTTPS, using a non-HTTPS connection between the proxy and Django. In this case, `is_secure()` would always return `False` – even for requests that were made via HTTPS by the end user.

In this situation, you’ll want to configure your proxy to set a custom HTTP header that tells Django whether the request came in via HTTPS, and you’ll want to set `SECURE_PROXY_SSL_HEADER` so that Django knows what header to look for.

You'll need to set a tuple with two elements – the name of the header to look for and the required value. For example:

```
SECURE_PROXY_SSL_HEADER = ('HTTP_X_FORWARDED_PROTO', 'https')
```

Here, we're telling Django that we trust the `X-Forwarded-Proto` header that comes from our proxy, and any time its value is `'https'`, then the request is guaranteed to be secure (i.e., it originally came in via HTTPS). Obviously, you should *only* set this setting if you control your proxy or have some other guarantee that it sets/strips this header appropriately.

Note that the header needs to be in the format as used by `request.META` – all caps and likely starting with `HTTP_`. (Remember, Django automatically adds `'HTTP_'` to the start of x-header names before making the header available in `request.META`.)

**Warning:** You will probably open security holes in your site if you set this without knowing what you're doing. And if you fail to set it when you should. Seriously.

Make sure ALL of the following are true before setting this (assuming the values from the example above):

- Your Django app is behind a proxy.
- Your proxy strips the `X-Forwarded-Proto` header from all incoming requests. In other words, if end users include that header in their requests, the proxy will discard it.
- Your proxy sets the `X-Forwarded-Proto` header and sends it to Django, but only for requests that originally come in via HTTPS.

If any of those are not true, you should keep this setting set to `None` and find another way of determining HTTPS, perhaps via custom middleware.

### `SECURE_REDIRECT_EXEMPT`

Default: [] (Empty list)

If a URL path matches a regular expression in this list, the request will not be redirected to HTTPS. If `SECURE_SSL_REDIRECT` is `False`, this setting has no effect.

### `SECURE_SSL_HOST`

Default: None

If a string (e.g. `secure.example.com`), all SSL redirects will be directed to this host rather than the originally-requested host (e.g. `www.example.com`). If `SECURE_SSL_REDIRECT` is `False`, this setting has no effect.

### `SECURE_SSL_REDIRECT`

Default: `False`

If `True`, the `SecurityMiddleware` *redirects* all non-HTTPS requests to HTTPS (except for those URLs matching a regular expression listed in `SECURE_REDIRECT_EXEMPT`).

**Note:** If turning this to `True` causes infinite redirects, it probably means your site is running behind a proxy and can't tell which requests are secure and which are not. Your proxy likely sets a header to indicate secure requests; you can

correct the problem by finding out what that header is and configuring the `SECURE_PROXY_SSL_HEADER` setting accordingly.

---

### **SERIALIZATION\_MODULES**

Default: Not defined

A dictionary of modules containing serializer definitions (provided as strings), keyed by a string identifier for that serialization type. For example, to define a YAML serializer, use:

```
SERIALIZATION_MODULES = {'yaml': 'path.to.yaml_serializer'}
```

### **SERVER\_EMAIL**

Default: 'root@localhost'

The email address that error messages come from, such as those sent to `ADMINS` and `MANAGERS`.

---

#### **Why are my emails sent from a different address?**

This address is used only for error messages. It is *not* the address that regular email messages sent with `send_mail()` come from; for that, see `DEFAULT_FROM_EMAIL`.

---

### **SHORT\_DATE\_FORMAT**

Default: 'm/d/Y' (e.g. 12/31/2003)

An available formatting that can be used for displaying date fields on templates. Note that if `USE_L10N` is set to True, then the corresponding locale-dictated format has higher precedence and will be applied. See *allowed date format strings*.

See also `DATE_FORMAT` and `SHORT_DATETIME_FORMAT`.

### **SHORT\_DATETIME\_FORMAT**

Default: 'm/d/Y P' (e.g. 12/31/2003 4 p.m.)

An available formatting that can be used for displaying datetime fields on templates. Note that if `USE_L10N` is set to True, then the corresponding locale-dictated format has higher precedence and will be applied. See *allowed date format strings*.

See also `DATE_FORMAT` and `SHORT_DATE_FORMAT`.

### **SIGNING\_BACKEND**

Default: 'django.core.signing.TimestampSigner'

The backend used for signing cookies and other data.

See also the *Cryptographic signing* documentation.

## SILENCED\_SYSTEM\_CHECKS

Default: [] (Empty list)

A list of identifiers of messages generated by the system check framework (i.e. ["models.W001"]) that you wish to permanently acknowledge and ignore. Silenced checks will not be output to the console.

In older versions, silenced messages of ERROR level or higher were printed to the console.

See also the *System check framework* documentation.

## TEMPLATES

Default: [] (Empty list)

A list containing the settings for all template engines to be used with Django. Each item of the list is a dictionary containing the options for an individual engine.

Here's a simple setup that tells the Django template engine to load templates from the `templates` subdirectory inside each installed application:

```
TEMPLATES = [  
    {  
        'BACKEND': 'django.template.backends.django.DjangoTemplates',  
        'APP_DIRS': True,  
    },  
]
```

The following options are available for all backends.

## BACKEND

Default: Not defined

The template backend to use. The built-in template backends are:

- 'django.template.backends.django.DjangoTemplates'
- 'django.template.backends.jinja2.Jinja2'

You can use a template backend that doesn't ship with Django by setting `BACKEND` to a fully-qualified path (i.e. 'mypackage.whatever.Backend').

## NAME

Default: see below

The alias for this particular template engine. It's an identifier that allows selecting an engine for rendering. Aliases must be unique across all configured template engines.

It defaults to the name of the module defining the engine class, i.e. the next to last piece of `BACKEND`, when it isn't provided. For example if the backend is 'mypackage.whatever.Backend' then its default name is 'whatever'.

## DIRS

Default: [] (Empty list)

Directories where the engine should look for template source files, in search order.

## APP\_DIRS

Default: False

Whether the engine should look for template source files inside installed applications.

---

**Note:** The default `settings.py` file created by `django-admin startproject` sets `'APP_DIRS': True`.

---

## OPTIONS

Default: {} (Empty dict)

Extra parameters to pass to the template backend. Available parameters vary depending on the template backend. See *DjangoTemplates* and *Jinja2* for the options of the built-in backends.

## TEST\_RUNNER

Default: `'django.test.runner.DiscoverRunner'`

The name of the class to use for starting the test suite. See *Using different testing frameworks*.

## TEST\_NON\_SERIALIZED\_APPS

Default: [] (Empty list)

In order to restore the database state between tests for `TransactionTestCases` and database backends without transactions, Django will *serialize the contents of all apps* when it starts the test run so it can then reload from that copy before running tests that need it.

This slows down the startup time of the test runner; if you have apps that you know don't need this feature, you can add their full names in here (e.g. `'django.contrib.contenttypes'`) to exclude them from this serialization process.

## THOUSAND\_SEPARATOR

Default: `' , '` (Comma)

Default thousand separator used when formatting numbers. This setting is used only when `USE_THOUSAND_SEPARATOR` is `True` and `NUMBER_GROUPING` is greater than 0.

Note that if `USE_L10N` is set to `True`, then the locale-dictated format has higher precedence and will be applied instead.

See also `NUMBER_GROUPING`, `DECIMAL_SEPARATOR` and `USE_THOUSAND_SEPARATOR`.

## TIME\_FORMAT

Default: 'P' (e.g. 4 p.m.)

The default formatting to use for displaying time fields in any part of the system. Note that if `USE_L10N` is set to `True`, then the locale-dictated format has higher precedence and will be applied instead. See *allowed date format strings*.

See also `DATE_FORMAT` and `DATETIME_FORMAT`.

## TIME\_INPUT\_FORMATS

Default:

```
[
    '%H:%M:%S',      # '14:30:59'
    '%H:%M:%S.%f',   # '14:30:59.000200'
    '%H:%M',         # '14:30'
]
```

A list of formats that will be accepted when inputting data on a time field. Formats will be tried in order, using the first valid one. Note that these format strings use Python's `datetime` module syntax, not the format strings from the `date` template filter.

When `USE_L10N` is `True`, the locale-dictated format has higher precedence and will be applied instead.

See also `DATE_INPUT_FORMATS` and `DATETIME_INPUT_FORMATS`.

## TIME\_ZONE

Default: 'America/Chicago'

A string representing the time zone for this installation, or `None`. See the [list of time zones](#).

---

**Note:** Since Django was first released with the `TIME_ZONE` set to 'America/Chicago', the global setting (used if nothing is defined in your project's `settings.py`) remains 'America/Chicago' for backwards compatibility. New project templates default to 'UTC'.

---

Note that this isn't necessarily the time zone of the server. For example, one server may serve multiple Django-powered sites, each with a separate time zone setting.

When `USE_TZ` is `False`, this is the time zone in which Django will store all datetimes. When `USE_TZ` is `True`, this is the default time zone that Django will use to display datetimes in templates and to interpret datetimes entered in forms.

Django sets the `os.environ['TZ']` variable to the time zone you specify in the `TIME_ZONE` setting. Thus, all your views and models will automatically operate in this time zone. However, Django won't set the `TZ` environment variable under the following conditions:

- If you're using the manual configuration option as described in *manually configuring settings*, or
- If you specify `TIME_ZONE = None`. This will cause Django to fall back to using the system timezone. However, this is discouraged when `USE_TZ = True`, because it makes conversions between local time and UTC less reliable.

If Django doesn't set the `TZ` environment variable, it's up to you to ensure your processes are running in the correct environment.

---

**Note:** Django cannot reliably use alternate time zones in a Windows environment. If you're running Django on Windows, `TIME_ZONE` must be set to match the system time zone.

---

### `USE_ETAGS`

Default: `False`

A boolean that specifies whether to output the `ETag` header. This saves bandwidth but slows down performance. This is used by the `CommonMiddleware` and in the `cache framework`.

### `USE_I18N`

Default: `True`

A boolean that specifies whether Django's translation system should be enabled. This provides an easy way to turn it off, for performance. If this is set to `False`, Django will make some optimizations so as not to load the translation machinery.

See also `LANGUAGE_CODE`, `USE_L10N` and `USE_TZ`.

---

**Note:** The default `settings.py` file created by `django-admin startproject` includes `USE_I18N = True` for convenience.

---

### `USE_L10N`

Default: `False`

A boolean that specifies if localized formatting of data will be enabled by default or not. If this is set to `True`, e.g. Django will display numbers and dates using the format of the current locale.

See also `LANGUAGE_CODE`, `USE_I18N` and `USE_TZ`.

---

**Note:** The default `settings.py` file created by `django-admin startproject` includes `USE_L10N = True` for convenience.

---

### `USE_THOUSAND_SEPARATOR`

Default: `False`

A boolean that specifies whether to display numbers using a thousand separator. When `USE_L10N` is set to `True` and if this is also set to `True`, Django will use the values of `THOUSAND_SEPARATOR` and `NUMBER_GROUPING` to format numbers unless the locale already has an existing thousands separator. If there is a thousands separator in the locale format, it will have higher precedence and will be applied instead.

See also `DECIMAL_SEPARATOR`, `NUMBER_GROUPING` and `THOUSAND_SEPARATOR`.

## USE\_TZ

Default: `False`

A boolean that specifies if datetimes will be timezone-aware by default or not. If this is set to `True`, Django will use timezone-aware datetimes internally. Otherwise, Django will use naive datetimes in local time.

See also `TIME_ZONE`, `USE_I18N` and `USE_L10N`.

---

**Note:** The default `settings.py` file created by `django-admin startproject` includes `USE_TZ = True` for convenience.

---

## USE\_X\_FORWARDED\_HOST

Default: `False`

A boolean that specifies whether to use the `X-Forwarded-Host` header in preference to the `Host` header. This should only be enabled if a proxy which sets this header is in use.

This setting takes priority over `USE_X_FORWARDED_PORT`. Per [RFC 7239#page-7](#), the `X-Forwarded-Host` header can include the port number, in which case you shouldn't use `USE_X_FORWARDED_PORT`.

## USE\_X\_FORWARDED\_PORT

Default: `False`

A boolean that specifies whether to use the `X-Forwarded-Port` header in preference to the `SERVER_PORT` META variable. This should only be enabled if a proxy which sets this header is in use.

`USE_X_FORWARDED_HOST` takes priority over this setting.

## WSGI\_APPLICATION

Default: `None`

The full Python path of the WSGI application object that Django's built-in servers (e.g. `runserver`) will use. The `django-admin startproject` management command will create a simple `wsgi.py` file with an application callable in it, and point this setting to that application.

If not set, the return value of `django.core.wsgi.get_wsgi_application()` will be used. In this case, the behavior of `runserver` will be identical to previous Django versions.

## YEAR\_MONTH\_FORMAT

Default: `'F Y'`

The default formatting to use for date fields on Django admin change-list pages – and, possibly, by other parts of the system – in cases when only the year and month are displayed.

For example, when a Django admin change-list page is being filtered by a date drilldown, the header for a given month displays the month and the year. Different locales have different formats. For example, U.S. English would say “January 2006,” whereas another locale might say “2006/January.”

Note that if `USE_L10N` is set to `True`, then the corresponding locale-dictated format has higher precedence and will be applied.

See *allowed date format strings*. See also `DATE_FORMAT`, `DATETIME_FORMAT`, `TIME_FORMAT` and `MONTH_DAY_FORMAT`.

#### `X_FRAME_OPTIONS`

Default: `'SAMEORIGIN'`

The default value for the X-Frame-Options header used by `XFrameOptionsMiddleware`. See the *clickjacking protection* documentation.

## 6.18.2 Auth

Settings for `django.contrib.auth`.

#### `AUTHENTICATION_BACKENDS`

Default: `['django.contrib.auth.backends.ModelBackend']`

A list of authentication backend classes (as strings) to use when attempting to authenticate a user. See the *authentication backends documentation* for details.

#### `AUTH_USER_MODEL`

Default: `'auth.User'`

The model to use to represent a User. See *Substituting a custom User model*.

**Warning:** You cannot change the `AUTH_USER_MODEL` setting during the lifetime of a project (i.e. once you have made and migrated models that depend on it) without serious effort. It is intended to be set at the project start, and the model it refers to must be available in the first migration of the app that it lives in. See *Substituting a custom User model* for more details.

#### `LOGIN_REDIRECT_URL`

Default: `'/accounts/profile/'`

The URL where requests are redirected after login when the `contrib.auth.login` view gets no `next` parameter.

This is used by the `login_required()` decorator, for example.

This setting also accepts *named URL patterns* which can be used to reduce configuration duplication since you don't have to define the URL in two places (`settings` and `URLconf`).

#### `LOGIN_URL`

Default: `'/accounts/login/'`

The URL where requests are redirected for login, especially when using the `login_required()` decorator.

This setting also accepts *named URL patterns* which can be used to reduce configuration duplication since you don't have to define the URL in two places (`settings` and `URLconf`).

### LOGOUT\_REDIRECT\_URL

Default: None

The URL where requests are redirected after a user logs out using the `logout()` view (if the view doesn't get a `next_page` argument).

If None, no redirect will be performed and the logout view will be rendered.

This setting also accepts *named URL patterns* which can be used to reduce configuration duplication since you don't have to define the URL in two places (`settings` and `URLconf`).

### PASSWORD\_RESET\_TIMEOUT\_DAYS

Default: 3

The number of days a password reset link is valid for. Used by the `django.contrib.auth` password reset mechanism.

### PASSWORD\_HASHERS

See *How Django stores passwords*.

Default:

```
[
    'django.contrib.auth.hashers.PBKDF2PasswordHasher',
    'django.contrib.auth.hashers.PBKDF2SHA1PasswordHasher',
    'django.contrib.auth.hashers.Argon2PasswordHasher',
    'django.contrib.auth.hashers.BCryptSHA256PasswordHasher',
    'django.contrib.auth.hashers.BCryptPasswordHasher',
]
```

The following hashers were removed from the defaults:

```
'django.contrib.auth.hashers.SHA1PasswordHasher'
'django.contrib.auth.hashers.MD5PasswordHasher'
'django.contrib.auth.hashers.UnsaltedSHA1PasswordHasher'
'django.contrib.auth.hashers.UnsaltedMD5PasswordHasher'
'django.contrib.auth.hashers.CryptPasswordHasher'
```

Consider using a *wrapped password hasher* to strengthen the hashes in your database. If that's not feasible, add this setting to your project and add back any hashers that you need.

Also, the `Argon2PasswordHasher` was added.

### AUTH\_PASSWORD\_VALIDATORS

Default: [] (Empty list)

The list of validators that are used to check the strength of user's passwords. See *Password validation* for more details. By default, no validation is performed and all passwords are accepted.

## 6.18.3 Messages

Settings for `django.contrib.messages`.

## MESSAGE\_LEVEL

Default: `messages.INFO`

Sets the minimum message level that will be recorded by the messages framework. See *message levels* for more details.

---

### Important

If you override `MESSAGE_LEVEL` in your settings file and rely on any of the built-in constants, you must import the constants module directly to avoid the potential for circular imports, e.g.:

```
from django.contrib.messages import constants as message_constants
MESSAGE_LEVEL = message_constants.DEBUG
```

If desired, you may specify the numeric values for the constants directly according to the values in the above *constants table*.

---

## MESSAGE\_STORAGE

Default: `'django.contrib.messages.storage.fallback.FallbackStorage'`

Controls where Django stores message data. Valid values are:

- `'django.contrib.messages.storage.fallback.FallbackStorage'`
- `'django.contrib.messages.storage.session.SessionStorage'`
- `'django.contrib.messages.storage.cookie.CookieStorage'`

See *message storage backends* for more details.

The backends that use cookies – *CookieStorage* and *FallbackStorage* – use the value of `SESSION_COOKIE_DOMAIN`, `SESSION_COOKIE_SECURE` and `SESSION_COOKIE_HTTPONLY` when setting their cookies.

## MESSAGE\_TAGS

Default:

```
{
    messages.DEBUG: 'debug',
    messages.INFO: 'info',
    messages.SUCCESS: 'success',
    messages.WARNING: 'warning',
    messages.ERROR: 'error',
}
```

This sets the mapping of message level to message tag, which is typically rendered as a CSS class in HTML. If you specify a value, it will extend the default. This means you only have to specify those values which you need to override. See *Displaying messages* above for more details.

---

### Important

If you override `MESSAGE_TAGS` in your settings file and rely on any of the built-in constants, you must import the constants module directly to avoid the potential for circular imports, e.g.:

```
from django.contrib.messages import constants as message_constants
MESSAGE_TAGS = {message_constants.INFO: ''}
```

If desired, you may specify the numeric values for the constants directly according to the values in the above *constants table*.

---

## 6.18.4 Sessions

Settings for *django.contrib.sessions*.

### **SESSION\_CACHE\_ALIAS**

Default: 'default'

If you're using *cache-based session storage*, this selects the cache to use.

### **SESSION\_COOKIE\_AGE**

Default: 1209600 (2 weeks, in seconds)

The age of session cookies, in seconds.

### **SESSION\_COOKIE\_DOMAIN**

Default: None

The domain to use for session cookies. Set this to a string such as ".example.com" (note the leading dot!) for cross-domain cookies, or use `None` for a standard domain cookie.

Be cautious when updating this setting on a production site. If you update this setting to enable cross-domain cookies on a site that previously used standard domain cookies, existing user cookies will be set to the old domain. This may result in them being unable to log in as long as these cookies persist.

This setting also affects cookies set by *django.contrib.messages*.

### **SESSION\_COOKIE\_HTTPONLY**

Default: True

Whether to use `HTTPOnly` flag on the session cookie. If this is set to `True`, client-side JavaScript will not be able to access the session cookie.

`HTTPOnly` is a flag included in a `Set-Cookie` HTTP response header. It is not part of the [RFC 2109](#) standard for cookies, and it isn't honored consistently by all browsers. However, when it is honored, it can be a useful way to mitigate the risk of a client side script accessing the protected cookie data.

Turning it on makes it less trivial for an attacker to escalate a cross-site scripting vulnerability into full hijacking of a user's session. There's not much excuse for leaving this off, either: if your code depends on reading session cookies from JavaScript, you're probably doing it wrong.

#### **SESSION\_COOKIE\_NAME**

Default: `'sessionid'`

The name of the cookie to use for sessions. This can be whatever you want (as long as it's different from the other cookie names in your application).

#### **SESSION\_COOKIE\_PATH**

Default: `'/'`

The path set on the session cookie. This should either match the URL path of your Django installation or be parent of that path.

This is useful if you have multiple Django instances running under the same hostname. They can use different cookie paths, and each instance will only see its own session cookie.

#### **SESSION\_COOKIE\_SECURE**

Default: `False`

Whether to use a secure cookie for the session cookie. If this is set to `True`, the cookie will be marked as “secure,” which means browsers may ensure that the cookie is only sent under an `HTTPS` connection.

Since it's trivial for a packet sniffer (e.g. [Firesheep](#)) to hijack a user's session if the session cookie is sent unencrypted, there's really no good excuse to leave this off. It will prevent you from using sessions on insecure requests and that's a good thing.

#### **SESSION\_ENGINE**

Default: `'django.contrib.sessions.backends.db'`

Controls where Django stores session data. Included engines are:

- `'django.contrib.sessions.backends.db'`
- `'django.contrib.sessions.backends.file'`
- `'django.contrib.sessions.backends.cache'`
- `'django.contrib.sessions.backends.cached_db'`
- `'django.contrib.sessions.backends.signed_cookies'`

See [Configuring the session engine](#) for more details.

#### **SESSION\_EXPIRE\_AT\_BROWSER\_CLOSE**

Default: `False`

Whether to expire the session when the user closes their browser. See [Browser-length sessions vs. persistent sessions](#).

#### SESSION\_FILE\_PATH

Default: `None`

If you're using file-based session storage, this sets the directory in which Django will store session data. When the default value (`None`) is used, Django will use the standard temporary directory for the system.

#### SESSION\_SAVE\_EVERY\_REQUEST

Default: `False`

Whether to save the session data on every request. If this is `False` (default), then the session data will only be saved if it has been modified – that is, if any of its dictionary values have been assigned or deleted. Empty sessions won't be created, even if this setting is active.

#### SESSION\_SERIALIZER

Default: `'django.contrib.sessions.serializers.JSONSerializer'`

Full import path of a serializer class to use for serializing session data. Included serializers are:

- `'django.contrib.sessions.serializers.PickleSerializer'`
- `'django.contrib.sessions.serializers.JSONSerializer'`

See *Session serialization* for details, including a warning regarding possible remote code execution when using *PickleSerializer*.

### 6.18.5 Sites

Settings for `django.contrib.sites`.

#### SITE\_ID

Default: Not defined

The ID, as an integer, of the current site in the `django_site` database table. This is used so that application data can hook into specific sites and a single database can manage content for multiple sites.

### 6.18.6 Static Files

Settings for `django.contrib.staticfiles`.

#### STATIC\_ROOT

Default: `None`

The absolute path to the directory where `collectstatic` will collect static files for deployment.

Example: `"/var/www/example.com/static/"`

If the `staticfiles` contrib app is enabled (as in the default project template), the `collectstatic` management command will collect static files into this directory. See the how-to on *managing static files* for more details about usage.

**Warning:** This should be an initially empty destination directory for collecting your static files from their permanent locations into one directory for ease of deployment; it is **not** a place to store your static files permanently. You should do that in directories that will be found by *staticfiles*'s *finders*, which by default, are 'static/' app sub-directories and any directories you include in *STATICFILES\_DIRS*).

## STATIC\_URL

Default: None

URL to use when referring to static files located in *STATIC\_ROOT*.

Example: `"/static/"` or `"http://static.example.com/"`

If not None, this will be used as the base path for *asset definitions* (the Media class) and the *staticfiles app*.

It must end in a slash if set to a non-empty value.

You may need to *configure these files to be served in development* and will definitely need to do so *in production*.

## STATICFILES\_DIRS

Default: [] (Empty list)

This setting defines the additional locations the staticfiles app will traverse if the FileSystemFinder finder is enabled, e.g. if you use the *collectstatic* or *findstatic* management command or use the static file serving view.

This should be set to a list of strings that contain full paths to your additional files directory(ies) e.g.:

```
STATICFILES_DIRS = [
    "/home/special.polls.com/polls/static",
    "/home/polls.com/polls/static",
    "/opt/webfiles/common",
]
```

Note that these paths should use Unix-style forward slashes, even on Windows (e.g. `"C:/Users/user/mysite/extra_static_content"`).

## Prefixes (optional)

In case you want to refer to files in one of the locations with an additional namespace, you can **optionally** provide a prefix as (prefix, path) tuples, e.g.:

```
STATICFILES_DIRS = [
    # ...
    ("downloads", "/opt/webfiles/stats"),
]
```

For example, assuming you have *STATIC\_URL* set to `'/static/'`, the *collectstatic* management command would collect the "stats" files in a 'downloads' subdirectory of *STATIC\_ROOT*.

This would allow you to refer to the local file `'/opt/webfiles/stats/polls_20101022.tar.gz'` with `'/static/downloads/polls_20101022.tar.gz'` in your templates, e.g.:

```
<a href="{% static "downloads/polls_20101022.tar.gz" %}">
```

### STATICFILES\_STORAGE

Default: `'django.contrib.staticfiles.storage.StaticFilesStorage'`

The file storage engine to use when collecting static files with the `collectstatic` management command.

A ready-to-use instance of the storage backend defined in this setting can be found at `django.contrib.staticfiles.storage.staticfiles_storage`.

For an example, see *Serving static files from a cloud service or CDN*.

### STATICFILES\_FINDERS

Default:

```
[
    'django.contrib.staticfiles.finders.FileSystemFinder',
    'django.contrib.staticfiles.finders.AppDirectoriesFinder',
]
```

The list of finder backends that know how to find static files in various locations.

The default will find files stored in the `STATICFILES_DIRS` setting (using `django.contrib.staticfiles.finders.FileSystemFinder`) and in a static subdirectory of each app (using `django.contrib.staticfiles.finders.AppDirectoriesFinder`). If multiple files with the same name are present, the first file that is found will be used.

One finder is disabled by default: `django.contrib.staticfiles.finders.DefaultStorageFinder`. If added to your `STATICFILES_FINDERS` setting, it will look for static files in the default file storage as defined by the `DEFAULT_FILE_STORAGE` setting.

---

**Note:** When using the `AppDirectoriesFinder` finder, make sure your apps can be found by staticfiles. Simply add the app to the `INSTALLED_APPS` setting of your site.

---

Static file finders are currently considered a private interface, and this interface is thus undocumented.

## 6.19 Signals

A list of all the signals that Django sends. All built-in signals are sent using the `send()` method.

### See also:

See the documentation on the [signal dispatcher](#) for information regarding how to register for and receive signals.

The [authentication framework](#) sends signals when a user is logged in / out.

## 6.19.1 Model signals

The `django.db.models.signals` module defines a set of signals sent by the model system.

**Warning:** Many of these signals are sent by various model methods like `__init__()` or `save()` that you can override in your own code.

If you override these methods on your model, you must call the parent class' methods for this signals to be sent.

Note also that Django stores signal handlers as weak references by default, so if your handler is a local function, it may be garbage collected. To prevent this, pass `weak=False` when you call the signal's `connect()`.

---

**Note:** Model signals sender model can be lazily referenced when connecting a receiver by specifying its full application label. For example, an `Answer` model defined in the `polls` application could be referenced as `'polls.Answer'`. This sort of reference can be quite handy when dealing with circular import dependencies and swappable models.

---

### `pre_init`

`django.db.models.signals.pre_init`

Whenever you instantiate a Django model, this signal is sent at the beginning of the model's `__init__()` method.

Arguments sent with this signal:

**sender** The model class that just had an instance created.

**args** A list of positional arguments passed to `__init__()`:

**kwargs** A dictionary of keyword arguments passed to `__init__()`:

For example, the *tutorial* has this line:

```
p = Poll(question="What's up?", pub_date=datetime.now())
```

The arguments sent to a `pre_init` handler would be:

Argument	Value
<code>sender</code>	<code>Poll</code> (the class itself)
<code>args</code>	<code>[]</code> (an empty list because there were no positional arguments passed to <code>__init__()</code> .)
<code>kwargs</code>	<code>{'question': "What's up?", 'pub_date': datetime.now() }</code>

### `post_init`

`django.db.models.signals.post_init`

Like `pre_init`, but this one is sent when the `__init__()` method finishes.

Arguments sent with this signal:

**sender** As above: the model class that just had an instance created.

**instance** The actual instance of the model that's just been created.

### `pre_save`

`django.db.models.signals.pre_save`

This is sent at the beginning of a model's `save()` method.

Arguments sent with this signal:

**sender** The model class.

**instance** The actual instance being saved.

**raw** A boolean; `True` if the model is saved exactly as presented (i.e. when loading a fixture). One should not query/modify other records in the database as the database might not be in a consistent state yet.

**using** The database alias being used.

**update\_fields** The set of fields to update as passed to `Model.save()`, or `None` if `update_fields` wasn't passed to `save()`.

### `post_save`

`django.db.models.signals.post_save`

Like `pre_save`, but sent at the end of the `save()` method.

Arguments sent with this signal:

**sender** The model class.

**instance** The actual instance being saved.

**created** A boolean; `True` if a new record was created.

**raw** A boolean; `True` if the model is saved exactly as presented (i.e. when loading a fixture). One should not query/modify other records in the database as the database might not be in a consistent state yet.

**using** The database alias being used.

**update\_fields** The set of fields to update as passed to `Model.save()`, or `None` if `update_fields` wasn't passed to `save()`.

### `pre_delete`

`django.db.models.signals.pre_delete`

Sent at the beginning of a model's `delete()` method and a queryset's `delete()` method.

Arguments sent with this signal:

**sender** The model class.

**instance** The actual instance being deleted.

**using** The database alias being used.

### `post_delete`

`django.db.models.signals.post_delete`

Like `pre_delete`, but sent at the end of a model's `delete()` method and a queryset's `delete()` method.

Arguments sent with this signal:

**sender** The model class.

**instance** The actual instance being deleted.

Note that the object will no longer be in the database, so be very careful what you do with this instance.

**using** The database alias being used.

### **m2m\_changed**

`django.db.models.signals.m2m_changed`

Sent when a *ManyToManyField* is changed on a model instance. Strictly speaking, this is not a model signal since it is sent by the *ManyToManyField*, but since it complements the *pre\_save/post\_save* and *pre\_delete/post\_delete* when it comes to tracking changes to models, it is included here.

Arguments sent with this signal:

**sender** The intermediate model class describing the *ManyToManyField*. This class is automatically created when a many-to-many field is defined; you can access it using the `through` attribute on the many-to-many field.

**instance** The instance whose many-to-many relation is updated. This can be an instance of the `sender`, or of the class the *ManyToManyField* is related to.

**action** A string indicating the type of update that is done on the relation. This can be one of the following:

"pre\_add" Sent *before* one or more objects are added to the relation.

"post\_add" Sent *after* one or more objects are added to the relation.

"pre\_remove" Sent *before* one or more objects are removed from the relation.

"post\_remove" Sent *after* one or more objects are removed from the relation.

"pre\_clear" Sent *before* the relation is cleared.

"post\_clear" Sent *after* the relation is cleared.

**reverse** Indicates which side of the relation is updated (i.e., if it is the forward or reverse relation that is being modified).

**model** The class of the objects that are added to, removed from or cleared from the relation.

**pk\_set** For the `pre_add`, `post_add`, `pre_remove` and `post_remove` actions, this is a set of primary key values that have been added to or removed from the relation.

For the `pre_clear` and `post_clear` actions, this is `None`.

**using** The database alias being used.

For example, if a `Pizza` can have multiple `Topping` objects, modeled like this:

```
class Topping(models.Model):
    # ...
    pass

class Pizza(models.Model):
    # ...
    toppings = models.ManyToManyField(Topping)
```

If we connected a handler like this:

```

from django.db.models.signals import m2m_changed

def toppings_changed(sender, **kwargs):
    # Do something
    pass

m2m_changed.connect(toppings_changed, sender=Pizza.toppings.through)

```

and then did something like this:

```

>>> p = Pizza.objects.create(...)
>>> t = Topping.objects.create(...)
>>> p.toppings.add(t)

```

the arguments sent to a `m2m_changed` handler (`toppings_changed` in the example above) would be:

Argument	Value
sender	<code>Pizza.toppings.through</code> (the intermediate m2m class)
instance	<code>p</code> (the <code>Pizza</code> instance being modified)
action	"pre_add" (followed by a separate signal with "post_add")
reverse	False (Pizza contains the <code>ManyToManyField</code> , so this call modifies the forward relation)
model	<code>Topping</code> (the class of the objects added to the <code>Pizza</code> )
pk_set	{ <code>t.id</code> } (since only <code>Topping t</code> was added to the relation)
using	"default" (since the default router sends writes here)

And if we would then do something like this:

```

>>> t.pizza_set.remove(p)

```

the arguments sent to a `m2m_changed` handler would be:

Argument	Value
sender	<code>Pizza.toppings.through</code> (the intermediate m2m class)
instance	<code>t</code> (the <code>Topping</code> instance being modified)
action	"pre_remove" (followed by a separate signal with "post_remove")
reverse	True (Pizza contains the <code>ManyToManyField</code> , so this call modifies the reverse relation)
model	<code>Pizza</code> (the class of the objects removed from the <code>Topping</code> )
pk_set	{ <code>p.id</code> } (since only <code>Pizza p</code> was removed from the relation)
using	"default" (since the default router sends writes here)

## class\_prepared

`django.db.models.signals.class_prepared`

Sent whenever a model class has been “prepared” – that is, once model has been defined and registered with Django’s model system. Django uses this signal internally; it’s not generally used in third-party applications.

Since this signal is sent during the app registry population process, and `AppConfig.ready()` runs after the app registry is fully populated, receivers cannot be connected in that method. One possibility is to connect them `AppConfig.__init__()` instead, taking care not to import models or trigger calls to the app registry.

Arguments that are sent with this signal:

**sender** The model class which was just prepared.

## 6.19.2 Management signals

Signals sent by *django-admin*.

### `pre_migrate`

`django.db.models.signals.pre_migrate`

Sent by the *migrate* command before it starts to install an application. It's not emitted for applications that lack a `models` module.

Arguments sent with this signal:

**sender** An *AppConfig* instance for the application about to be migrated/synced.

**app\_config** Same as `sender`.

**verbosity** Indicates how much information `manage.py` is printing on screen. See the `--verbosity` flag for details.

Functions which listen for *pre\_migrate* should adjust what they output to the screen based on the value of this argument.

**interactive** If `interactive` is `True`, it's safe to prompt the user to input things on the command line. If `interactive` is `False`, functions which listen for this signal should not try to prompt for anything.

For example, the *django.contrib.auth* app only prompts to create a superuser when `interactive` is `True`.

**using** The alias of database on which a command will operate.

**plan** The migration plan that is going to be used for the migration run. While the plan is not public API, this allows for the rare cases when it is necessary to know the plan. A plan is a list of two-tuples with the first item being the instance of a migration class and the second item showing if the migration was rolled back (`True`) or applied (`False`).

**apps** An instance of *Apps* containing the state of the project before the migration run. It should be used instead of the global *apps* registry to retrieve the models you want to perform operations on.

### `post_migrate`

`django.db.models.signals.post_migrate`

Sent at the end of the *migrate* (even if no migrations are run) and *flush* commands. It's not emitted for applications that lack a `models` module.

Handlers of this signal must not perform database schema alterations as doing so may cause the *flush* command to fail if it runs during the *migrate* command.

Arguments sent with this signal:

**sender** An *AppConfig* instance for the application that was just installed.

**app\_config** Same as `sender`.

**verbosity** Indicates how much information `manage.py` is printing on screen. See the `--verbosity` flag for details.

Functions which listen for *post\_migrate* should adjust what they output to the screen based on the value of this argument.

**interactive** If `interactive` is `True`, it's safe to prompt the user to input things on the command line. If `interactive` is `False`, functions which listen for this signal should not try to prompt for anything.

For example, the `django.contrib.auth` app only prompts to create a superuser when `interactive` is `True`.

**using** The database alias used for synchronization. Defaults to the `default` database.

**plan** The migration plan that was used for the migration run. While the plan is not public API, this allows for the rare cases when it is necessary to know the plan. A plan is a list of two-tuples with the first item being the instance of a migration class and the second item showing if the migration was rolled back (`True`) or applied (`False`).

**apps** An instance of `Apps` containing the state of the project after the migration run. It should be used instead of the global `apps` registry to retrieve the models you want to perform operations on.

For example, you could register a callback in an `AppConfig` like this:

```
from django.apps import AppConfig
from django.db.models.signals import post_migrate

def my_callback(sender, **kwargs):
    # Your specific logic here
    pass

class MyAppConfig(AppConfig):
    ...

    def ready(self):
        post_migrate.connect(my_callback, sender=self)
```

---

**Note:** If you provide an `AppConfig` instance as the `sender` argument, please ensure that the signal is registered in `ready()`. `AppConfigs` are recreated for tests that run with a modified set of `INSTALLED_APPS` (such as when settings are overridden) and such signals should be connected for each new `AppConfig` instance.

---

### 6.19.3 Request/response signals

Signals sent by the core framework when processing a request.

#### `request_started`

`django.core.signals.request_started`

Sent when Django begins processing an HTTP request.

Arguments sent with this signal:

**sender** The handler class – e.g. `django.core.handlers.wsgi.WsgiHandler` – that handled the request.

**environ** The environ dictionary provided to the request.

#### `request_finished`

`django.core.signals.request_finished`

Sent when Django finishes delivering an HTTP response to the client.

---

**Note:** Some WSGI servers and middleware do not always call `close` on the response object after handling a request, most notably uWSGI prior to 1.2.6 and Sentry’s error reporting middleware up to 2.0.7. In those cases this signal isn’t sent at all. This can result in idle connections to database and memcache servers.

---

Arguments sent with this signal:

**sender** The handler class, as above.

#### `got_request_exception`

`django.core.signals.got_request_exception`

This signal is sent whenever Django encounters an exception while processing an incoming HTTP request.

Arguments sent with this signal:

**sender** The handler class, as above.

**request** The *HttpRequest* object.

## 6.19.4 Test signals

Signals only sent when *running tests*.

#### `setting_changed`

`django.test.signals.setting_changed`

This signal is sent when the value of a setting is changed through the `django.test.TestCase.settings()` context manager or the `django.test.override_settings()` decorator/context manager.

It’s actually sent twice: when the new value is applied (“setup”) and when the original value is restored (“teardown”). Use the `enter` argument to distinguish between the two.

You can also import this signal from `django.core.signals` to avoid importing from `django.test` in non-test situations.

Arguments sent with this signal:

**sender** The settings handler.

**setting** The name of the setting.

**value** The value of the setting after the change. For settings that initially don’t exist, in the “teardown” phase, `value` is `None`.

**enter** A boolean; `True` if the setting is applied, `False` if restored.

#### `template_rendered`

`django.test.signals.template_rendered`

Sent when the test system renders a template. This signal is not emitted during normal operation of a Django server – it is only available during testing.

Arguments sent with this signal:

**sender** The *Template* object which was rendered.

**template** Same as sender

**context** The *Context* with which the template was rendered.

## 6.19.5 Database Wrappers

Signals sent by the database wrapper when a database connection is initiated.

### `connection_created`

`django.db.backends.signals.connection_created`

Sent when the database wrapper makes the initial connection to the database. This is particularly useful if you'd like to send any post connection commands to the SQL backend.

Arguments sent with this signal:

**sender** The database wrapper class – i.e. `django.db.backends.postgresql.DatabaseWrapper` or `django.db.backends.mysql.DatabaseWrapper`, etc.

**connection** The database connection that was opened. This can be used in a multiple-database configuration to differentiate connection signals from different databases.

## 6.20 Templates

Django's template engine provides a powerful mini-language for defining the user-facing layer of your application, encouraging a clean separation of application and presentation logic. Templates can be maintained by anyone with an understanding of HTML; no knowledge of Python is required. For introductory material, see *Templates* topic guide.

### 6.20.1 The Django template language

This document explains the language syntax of the Django template system. If you're looking for a more technical perspective on how it works and how to extend it, see *The Django template language: for Python programmers*.

Django's template language is designed to strike a balance between power and ease. It's designed to feel comfortable to those used to working with HTML. If you have any exposure to other text-based template languages, such as *Smarty* or *Jinja2*, you should feel right at home with Django's templates.

---

#### Philosophy

If you have a background in programming, or if you're used to languages which mix programming code directly into HTML, you'll want to bear in mind that the Django template system is not simply Python embedded into HTML. This is by design: the template system is meant to express presentation, not program logic.

The Django template system provides tags which function similarly to some programming constructs – an *if* tag for boolean tests, a *for* tag for looping, etc. – but these are not simply executed as the corresponding Python code, and the template system will not execute arbitrary Python expressions. Only the tags, filters and syntax listed below are supported by default (although you can add *your own extensions* to the template language as needed).

---

## Templates

A template is simply a text file. It can generate any text-based format (HTML, XML, CSV, etc.).

A template contains **variables**, which get replaced with values when the template is evaluated, and **tags**, which control the logic of the template.

Below is a minimal template that illustrates a few basics. Each element will be explained later in this document.

```
{% extends "base_generic.html" %}

{% block title %}{{ section.title }}{% endblock %}

{% block content %}
<h1>{{ section.title }}</h1>

{% for story in story_list %}
<h2>
  <a href="{{ story.get_absolute_url }}">
    {{ story.headline|upper }}
  </a>
</h2>
<p>{{ story.tease|truncatewords:"100" }}</p>
{% endfor %}
{% endblock %}
```

---

## Philosophy

Why use a text-based template instead of an XML-based one (like Zope's TAL)? We wanted Django's template language to be usable for more than just XML/HTML templates. At World Online, we use it for emails, JavaScript and CSV. You can use the template language for any text-based format.

Oh, and one more thing: making humans edit XML is sadistic!

---

## Variables

Variables look like this: `{{ variable }}`. When the template engine encounters a variable, it evaluates that variable and replaces it with the result. Variable names consist of any combination of alphanumeric characters and the underscore ("`_`"). The dot ("`.`") also appears in variable sections, although that has a special meaning, as indicated below. Importantly, *you cannot have spaces or punctuation characters in variable names*.

Use a dot (`.`) to access attributes of a variable.

---

## Behind the scenes

Technically, when the template system encounters a dot, it tries the following lookups, in this order:

- Dictionary lookup
- Attribute or method lookup
- Numeric index lookup

If the resulting value is callable, it is called with no arguments. The result of the call becomes the template value.

This lookup order can cause some unexpected behavior with objects that override dictionary lookup. For example, consider the following code snippet that attempts to loop over a `collections.defaultdict`:

```
{% for k, v in defaultdict.iteritems %}
    Do something with k and v here...
{% endfor %}
```

Because dictionary lookup happens first, that behavior kicks in and provides a default value instead of using the intended `.iteritems()` method. In this case, consider converting to a dictionary first.

In the above example, `{{ section.title }}` will be replaced with the `title` attribute of the `section` object.

If you use a variable that doesn't exist, the template system will insert the value of the `string_if_invalid` option, which is set to `' '` (the empty string) by default.

Note that “bar” in a template expression like `{{ foo.bar }}` will be interpreted as a literal string and not using the value of the variable “bar”, if one exists in the template context.

## Filters

You can modify variables for display by using **filters**.

Filters look like this: `{{ name|lower }}`. This displays the value of the `{{ name }}` variable after being filtered through the `lower` filter, which converts text to lowercase. Use a pipe (`|`) to apply a filter.

Filters can be “chained.” The output of one filter is applied to the next. `{{ text|escape|linebreaks }}` is a common idiom for escaping text contents, then converting line breaks to `<p>` tags.

Some filters take arguments. A filter argument looks like this: `{{ bio|truncatewords:30 }}`. This will display the first 30 words of the `bio` variable.

Filter arguments that contain spaces must be quoted; for example, to join a list with commas and spaces you'd use `{{ list|join:", " }}`.

Django provides about sixty built-in template filters. You can read all about them in the [built-in filter reference](#). To give you a taste of what's available, here are some of the more commonly used template filters:

**default** If a variable is false or empty, use given default. Otherwise, use the value of the variable. For example:

```
{{ value|default:"nothing" }}
```

If `value` isn't provided or is empty, the above will display “nothing”.

**length** Returns the length of the value. This works for both strings and lists. For example:

```
{{ value|length }}
```

If `value` is `['a', 'b', 'c', 'd']`, the output will be 4.

**filesizeformat** Formats the value like a “human-readable” file size (i.e. `'13 KB'`, `'4.1 MB'`, `'102 bytes'`, etc.). For example:

```
{{ value|filesizeformat }}
```

If `value` is `123456789`, the output would be `117.7 MB`.

Again, these are just a few examples; see the [built-in filter reference](#) for the complete list.

You can also create your own custom template filters; see [Custom template tags and filters](#).

**See also:**

Django’s admin interface can include a complete reference of all template tags and filters available for a given site. See *The Django admin documentation generator*.

## Tags

Tags look like this: `{% tag %}`. Tags are more complex than variables: Some create text in the output, some control flow by performing loops or logic, and some load external information into the template to be used by later variables.

Some tags require beginning and ending tags (i.e. `{% tag %} ... tag contents ... {% endtag %}`).

Django ships with about two dozen built-in template tags. You can read all about them in the *built-in tag reference*. To give you a taste of what’s available, here are some of the more commonly used tags:

**for** Loop over each item in an array. For example, to display a list of athletes provided in `athlete_list`:

```
<ul>
{% for athlete in athlete_list %}
  <li>{{ athlete.name }}</li>
{% endfor %}
</ul>
```

**if, elif, and else** Evaluates a variable, and if that variable is “true” the contents of the block are displayed:

```
{% if athlete_list %}
  Number of athletes: {{ athlete_list|length }}
{% elif athlete_in_locker_room_list %}
  Athletes should be out of the locker room soon!
{% else %}
  No athletes.
{% endif %}
```

In the above, if `athlete_list` is not empty, the number of athletes will be displayed by the `{{ athlete_list|length }}` variable. Otherwise, if `athlete_in_locker_room_list` is not empty, the message “Athletes should be out...” will be displayed. If both lists are empty, “No athletes.” will be displayed.

You can also use filters and various operators in the *if* tag:

```
{% if athlete_list|length > 1 %}
  Team: {% for athlete in athlete_list %} ... {% endfor %}
{% else %}
  Athlete: {{ athlete_list.0.name }}
{% endif %}
```

While the above example works, be aware that most template filters return strings, so mathematical comparisons using filters will generally not work as you expect. *length* is an exception.

**block and extends** Set up *template inheritance* (see below), a powerful way of cutting down on “boilerplate” in templates.

Again, the above is only a selection of the whole list; see the *built-in tag reference* for the complete list.

You can also create your own custom template tags; see *Custom template tags and filters*.

### See also:

Django’s admin interface can include a complete reference of all template tags and filters available for a given site. See *The Django admin documentation generator*.

## Comments

To comment-out part of a line in a template, use the comment syntax: `{# #}`.

For example, this template would render as 'hello':

```
{# greeting #}hello
```

A comment can contain any template code, invalid or not. For example:

```
{# {% if foo %}bar{% else %} #}
```

This syntax can only be used for single-line comments (no newlines are permitted between the `{#` and `#}` delimiters). If you need to comment out a multiline portion of the template, see the [comment](#) tag.

## Template inheritance

The most powerful – and thus the most complex – part of Django’s template engine is template inheritance. Template inheritance allows you to build a base “skeleton” template that contains all the common elements of your site and defines **blocks** that child templates can override.

It’s easiest to understand template inheritance by starting with an example:

```
<!DOCTYPE html>
<html lang="en">
<head>
  <link rel="stylesheet" href="style.css" />
  <title>{% block title %}My amazing site{% endblock %}</title>
</head>

<body>
  <div id="sidebar">
    {% block sidebar %}
    <ul>
      <li><a href="/">Home</a></li>
      <li><a href="/blog/">Blog</a></li>
    </ul>
    {% endblock %}
  </div>

  <div id="content">
    {% block content %}{% endblock %}
  </div>
</body>
</html>
```

This template, which we’ll call `base.html`, defines a simple HTML skeleton document that you might use for a simple two-column page. It’s the job of “child” templates to fill the empty blocks with content.

In this example, the `block` tag defines three blocks that child templates can fill in. All the `block` tag does is to tell the template engine that a child template may override those portions of the template.

A child template might look like this:

```
{% extends "base.html" %}

{% block title %}My amazing blog{% endblock %}
```

```
{% block content %}
{% for entry in blog_entries %}
    <h2>{{ entry.title }}</h2>
    <p>{{ entry.body }}</p>
{% endfor %}
{% endblock %}
```

The `extends` tag is the key here. It tells the template engine that this template “extends” another template. When the template system evaluates this template, first it locates the parent – in this case, “base.html”.

At that point, the template engine will notice the three `block` tags in `base.html` and replace those blocks with the contents of the child template. Depending on the value of `blog_entries`, the output might look like:

```
<!DOCTYPE html>
<html lang="en">
<head>
    <link rel="stylesheet" href="style.css" />
    <title>My amazing blog</title>
</head>

<body>
    <div id="sidebar">
        <ul>
            <li><a href="/">Home</a></li>
            <li><a href="/blog/">Blog</a></li>
        </ul>
    </div>

    <div id="content">
        <h2>Entry one</h2>
        <p>This is my first entry.</p>

        <h2>Entry two</h2>
        <p>This is my second entry.</p>
    </div>
</body>
</html>
```

Note that since the child template didn’t define the `sidebar` block, the value from the parent template is used instead. Content within a `{% block %}` tag in a parent template is always used as a fallback.

You can use as many levels of inheritance as needed. One common way of using inheritance is the following three-level approach:

- Create a `base.html` template that holds the main look-and-feel of your site.
- Create a `base_SECTIONNAME.html` template for each “section” of your site. For example, `base_news.html`, `base_sports.html`. These templates all extend `base.html` and include section-specific styles/design.
- Create individual templates for each type of page, such as a news article or blog entry. These templates extend the appropriate section template.

This approach maximizes code reuse and makes it easy to add items to shared content areas, such as section-wide navigation.

Here are some tips for working with inheritance:

- If you use `{% extends %}` in a template, it must be the first template tag in that template. Template inheritance won’t work, otherwise.

- More `{% block %}` tags in your base templates are better. Remember, child templates don't have to define all parent blocks, so you can fill in reasonable defaults in a number of blocks, then only define the ones you need later. It's better to have more hooks than fewer hooks.
- If you find yourself duplicating content in a number of templates, it probably means you should move that content to a `{% block %}` in a parent template.
- If you need to get the content of the block from the parent template, the `{{ block.super }}` variable will do the trick. This is useful if you want to add to the contents of a parent block instead of completely overriding it. Data inserted using `{{ block.super }}` will not be automatically escaped (see the *next section*), since it was already escaped, if necessary, in the parent template.
- For extra readability, you can optionally give a *name* to your `{% endblock %}` tag. For example:

```
{% block content %}
...
{% endblock content %}
```

In larger templates, this technique helps you see which `{% block %}` tags are being closed.

Finally, note that you can't define multiple `block` tags with the same name in the same template. This limitation exists because a block tag works in "both" directions. That is, a block tag doesn't just provide a hole to fill – it also defines the content that fills the hole in the *parent*. If there were two similarly-named `block` tags in a template, that template's parent wouldn't know which one of the blocks' content to use.

## Automatic HTML escaping

When generating HTML from templates, there's always a risk that a variable will include characters that affect the resulting HTML. For example, consider this template fragment:

```
Hello, {{ name }}
```

At first, this seems like a harmless way to display a user's name, but consider what would happen if the user entered their name as this:

```
<script>alert('hello')</script>
```

With this name value, the template would be rendered as:

```
Hello, <script>alert('hello')</script>
```

...which means the browser would pop-up a JavaScript alert box!

Similarly, what if the name contained a `'<` symbol, like this?

```
<b>username
```

That would result in a rendered template like this:

```
Hello, <b>username
```

...which, in turn, would result in the remainder of the Web page being bolded!

Clearly, user-submitted data shouldn't be trusted blindly and inserted directly into your Web pages, because a malicious user could use this kind of hole to do potentially bad things. This type of security exploit is called a [Cross Site Scripting \(XSS\)](#) attack.

To avoid this problem, you have two options:

- One, you can make sure to run each untrusted variable through the `escape` filter (documented below), which converts potentially harmful HTML characters to unarmful ones. This was the default solution in Django for its first few years, but the problem is that it puts the onus on *you*, the developer / template author, to ensure you're escaping everything. It's easy to forget to escape data.
- Two, you can take advantage of Django's automatic HTML escaping. The remainder of this section describes how auto-escaping works.

By default in Django, every template automatically escapes the output of every variable tag. Specifically, these five characters are escaped:

- `<` is converted to `&lt;`;
- `>` is converted to `&gt;`;
- `'` (single quote) is converted to `&#39;`;
- `"` (double quote) is converted to `&quot;`;
- `&` is converted to `&amp;`;

Again, we stress that this behavior is on by default. If you're using Django's template system, you're protected.

## How to turn it off

If you don't want data to be auto-escaped, on a per-site, per-template level or per-variable level, you can turn it off in several ways.

Why would you want to turn it off? Because sometimes, template variables contain data that you *intend* to be rendered as raw HTML, in which case you don't want their contents to be escaped. For example, you might store a blob of HTML in your database and want to embed that directly into your template. Or, you might be using Django's template system to produce text that is *not* HTML – like an email message, for instance.

## For individual variables

To disable auto-escaping for an individual variable, use the `safe` filter:

```
This will be escaped: {{ data }}
This will not be escaped: {{ data|safe }}
```

Think of `safe` as shorthand for *safe from further escaping* or *can be safely interpreted as HTML*. In this example, if `data` contains `'<b>'`, the output will be:

```
This will be escaped: &lt;b&gt;
This will not be escaped: <b>
```

## For template blocks

To control auto-escaping for a template, wrap the template (or just a particular section of the template) in the `autoescape` tag, like so:

```
{% autoescape off %}
  Hello {{ name }}
{% endautoescape %}
```

The `autoescape` tag takes either `on` or `off` as its argument. At times, you might want to force auto-escaping when it would otherwise be disabled. Here is an example template:

```
Auto-escaping is on by default. Hello {{ name }}

{% autoescape off %}
    This will not be auto-escaped: {{ data }}.

    Nor this: {{ other_data }}
    {% autoescape on %}
        Auto-escaping applies again: {{ name }}
    {% endautoescape %}
{% endautoescape %}
```

The auto-escaping tag passes its effect onto templates that extend the current one as well as templates included via the `include` tag, just like all block tags. For example:

```
base.html

{% autoescape off %}
<h1>{% block title %}{% endblock %}</h1>
{% block content %}
{% endblock %}
{% endautoescape %}

child.html

{% extends "base.html" %}
{% block title %}This & that{% endblock %}
{% block content %}{{ greeting }}{% endblock %}
```

Because auto-escaping is turned off in the base template, it will also be turned off in the child template, resulting in the following rendered HTML when the `greeting` variable contains the string `<b>Hello!</b>`:

```
<h1>This & that</h1>
<b>Hello!</b>
```

## Notes

Generally, template authors don't need to worry about auto-escaping very much. Developers on the Python side (people writing views and custom filters) need to think about the cases in which data shouldn't be escaped, and mark data appropriately, so things Just Work in the template.

If you're creating a template that might be used in situations where you're not sure whether auto-escaping is enabled, then add an `escape` filter to any variable that needs escaping. When auto-escaping is on, there's no danger of the `escape` filter *double-escaping* data – the `escape` filter does not affect auto-escaped variables.

## String literals and automatic escaping

As we mentioned earlier, filter arguments can be strings:

```
{{ data|default:"This is a string literal." }}
```

All string literals are inserted **without** any automatic escaping into the template – they act as if they were all passed through the `safe` filter. The reasoning behind this is that the template author is in control of what goes into the string literal, so they can make sure the text is correctly escaped when the template is written.

This means you would write

```
{{ data|default:"3 &lt; 2" }}
```

...rather than:

```
{{ data|default:"3 < 2" }} {# Bad! Don't do this. #}
```

This doesn't affect what happens to data coming from the variable itself. The variable's contents are still automatically escaped, if necessary, because they're beyond the control of the template author.

## Accessing method calls

Most method calls attached to objects are also available from within templates. This means that templates have access to much more than just class attributes (like field names) and variables passed in from views. For example, the Django ORM provides the “*entry\_set*” syntax for finding a collection of objects related on a foreign key. Therefore, given a model called “comment” with a foreign key relationship to a model called “task” you can loop through all comments attached to a given task like this:

```
{% for comment in task.comment_set.all %}
    {{ comment }}
{% endfor %}
```

Similarly, *QuerySets* provide a `count()` method to count the number of objects they contain. Therefore, you can obtain a count of all comments related to the current task with:

```
{{ task.comment_set.all.count }}
```

And of course you can easily access methods you've explicitly defined on your own models:

```
models.py
```

```
class Task(models.Model):
    def foo(self):
        return "bar"
```

```
template.html
```

```
{{ task.foo }}
```

Because Django intentionally limits the amount of logic processing available in the template language, it is not possible to pass arguments to method calls accessed from within templates. Data should be calculated in views, then passed to templates for display.

## Custom tag and filter libraries

Certain applications provide custom tag and filter libraries. To access them in a template, ensure the application is in `INSTALLED_APPS` (we'd add `'django.contrib.humanize'` for this example), and then use the *load* tag in a template:

```
{% load humanize %}
{{ 45000|intcomma }}
```

In the above, the *load* tag loads the *humanize* tag library, which then makes the *intcomma* filter available for use. If you've enabled `django.contrib.admindocs`, you can consult the documentation area in your admin to find the list of custom libraries in your installation.

The `load` tag can take multiple library names, separated by spaces. Example:

```
{% load humanize i18n %}
```

See *Custom template tags and filters* for information on writing your own custom template libraries.

## Custom libraries and template inheritance

When you load a custom tag or filter library, the tags/filters are only made available to the current template – not any parent or child templates along the template-inheritance path.

For example, if a template `foo.html` has `{% load humanize %}`, a child template (e.g., one that has `{% extends "foo.html" %}`) will *not* have access to the `humanize` template tags and filters. The child template is responsible for its own `{% load humanize %}`.

This is a feature for the sake of maintainability and sanity.

### See also:

*The Templates Reference* Covers built-in tags, built-in filters, using an alternative template, language, and more.

## 6.20.2 Built-in template tags and filters

This document describes Django’s built-in template tags and filters. It is recommended that you use the *automatic documentation*, if available, as this will also include documentation for any custom tags or filters installed.

### Built-in tag reference

#### `autoescape`

Controls the current auto-escaping behavior. This tag takes either `on` or `off` as an argument and that determines whether auto-escaping is in effect inside the block. The block is closed with an `endautoescape` ending tag.

When auto-escaping is in effect, all variable content has HTML escaping applied to it before placing the result into the output (but after any filters have been applied). This is equivalent to manually applying the `escape` filter to each variable.

The only exceptions are variables that are already marked as “safe” from escaping, either by the code that populated the variable, or because it has had the `safe` or `escape` filters applied.

Sample usage:

```
{% autoescape on %}
  {{ body }}
{% endautoescape %}
```

#### `block`

Defines a block that can be overridden by child templates. See *Template inheritance* for more information.

### comment

Ignores everything between `{% comment %}` and `{% endcomment %}`. An optional note may be inserted in the first tag. For example, this is useful when commenting out code for documenting why the code was disabled.

Sample usage:

```
<p>Rendered text with {{ pub_date|date:"c" }}</p>
{% comment "Optional note" %}
  <p>Commented out text with {{ create_date|date:"c" }}</p>
{% endcomment %}
```

`comment` tags cannot be nested.

### csrf\_token

This tag is used for CSRF protection, as described in the documentation for *Cross Site Request Forgeries*.

### cycle

Produces one of its arguments each time this tag is encountered. The first argument is produced on the first encounter, the second argument on the second encounter, and so forth. Once all arguments are exhausted, the tag cycles to the first argument and produces it again.

This tag is particularly useful in a loop:

```
{% for o in some_list %}
  <tr class="{% cycle 'row1' 'row2' %}">
    ...
  </tr>
{% endfor %}
```

The first iteration produces HTML that refers to class `row1`, the second to `row2`, the third to `row1` again, and so on for each iteration of the loop.

You can use variables, too. For example, if you have two template variables, `rowvalue1` and `rowvalue2`, you can alternate between their values like this:

```
{% for o in some_list %}
  <tr class="{% cycle rowvalue1 rowvalue2 %}">
    ...
  </tr>
{% endfor %}
```

Variables included in the cycle will be escaped. You can disable auto-escaping with:

```
{% for o in some_list %}
  <tr class="{% autoescape off %}{% cycle rowvalue1 rowvalue2 %}{% endautoescape %}">
    ...
  </tr>
{% endfor %}
```

You can mix variables and strings:

```
{% for o in some_list %}
  <tr class="{% cycle 'row1' rowvalue2 'row3' %}">
    ...
  </tr>
{% endfor %}
```

In some cases you might want to refer to the current value of a cycle without advancing to the next value. To do this, just give the `{% cycle %}` tag a name, using “as”, like this:

```
{% cycle 'row1' 'row2' as rowcolors %}
```

From then on, you can insert the current value of the cycle wherever you’d like in your template by referencing the cycle name as a context variable. If you want to move the cycle to the next value independently of the original `cycle` tag, you can use another `cycle` tag and specify the name of the variable. So, the following template:

```
<tr>
  <td class="{% cycle 'row1' 'row2' as rowcolors %}">...</td>
  <td class="{% rowcolors %}">...</td>
</tr>
<tr>
  <td class="{% cycle rowcolors %}">...</td>
  <td class="{% rowcolors %}">...</td>
</tr>
```

would output:

```
<tr>
  <td class="row1">...</td>
  <td class="row1">...</td>
</tr>
<tr>
  <td class="row2">...</td>
  <td class="row2">...</td>
</tr>
```

You can use any number of values in a `cycle` tag, separated by spaces. Values enclosed in single quotes (') or double quotes (") are treated as string literals, while values without quotes are treated as template variables.

By default, when you use the `as` keyword with the `cycle` tag, the usage of `{% cycle %}` that initiates the cycle will itself produce the first value in the cycle. This could be a problem if you want to use the value in a nested loop or an included template. If you only want to declare the cycle but not produce the first value, you can add a `silent` keyword as the last keyword in the tag. For example:

```
{% for obj in some_list %}
  {% cycle 'row1' 'row2' as rowcolors silent %}
  <tr class="{% rowcolors %}">{% include "subtemplate.html" %}</tr>
{% endfor %}
```

This will output a list of `<tr>` elements with `class` alternating between `row1` and `row2`. The subtemplate will have access to `rowcolors` in its context and the value will match the class of the `<tr>` that encloses it. If the `silent` keyword were to be omitted, `row1` and `row2` would be emitted as normal text, outside the `<tr>` element.

When the `silent` keyword is used on a cycle definition, the silence automatically applies to all subsequent uses of that specific cycle tag. The following template would output *nothing*, even though the second call to `{% cycle %}` doesn’t specify `silent`:

```
{% cycle 'row1' 'row2' as rowcolors silent %}
{% cycle rowcolors %}
```

## debug

Outputs a whole load of debugging information, including the current context and imported modules.

## extends

Signals that this template extends a parent template.

This tag can be used in two ways:

- `{% extends "base.html" %}` (with quotes) uses the literal value `"base.html"` as the name of the parent template to extend.
- `{% extends variable %}` uses the value of `variable`. If the variable evaluates to a string, Django will use that string as the name of the parent template. If the variable evaluates to a `Template` object, Django will use that object as the parent template.

See [Template inheritance](#) for more information.

A string argument may be a relative path starting with `./` or `../`. For example, assume the following directory structure:

```
dir1/
  template.html
  base2.html
  my/
    base3.html
base1.html
```

In `template.html`, the following paths would be valid:

```
{% extends "./base2.html" %}
{% extends "../base1.html" %}
{% extends "./my/base3.html" %}
```

The ability to use relative paths was added.

## filter

Filters the contents of the block through one or more filters. Multiple filters can be specified with pipes and filters can have arguments, just as in variable syntax.

Note that the block includes *all* the text between the `filter` and `endfilter` tags.

Sample usage:

```
{% filter force_escape|lower %}
  This text will be HTML-escaped, and will appear in all lowercase.
{% endfilter %}
```

---

**Note:** The `escape` and `safe` filters are not acceptable arguments. Instead, use the `autoescape` tag to manage autoescaping for blocks of template code.

---

## firstof

Outputs the first argument variable that is not `False`. Outputs nothing if all the passed variables are `False`.

Sample usage:

```
{% firstof var1 var2 var3 %}
```

This is equivalent to:

```
{% if var1 %}
  {{ var1 }}
{% elif var2 %}
  {{ var2 }}
{% elif var3 %}
  {{ var3 }}
{% endif %}
```

You can also use a literal string as a fallback value in case all passed variables are `False`:

```
{% firstof var1 var2 var3 "fallback value" %}
```

This tag auto-escapes variable values. You can disable auto-escaping with:

```
{% autoescape off %}
  {% firstof var1 var2 var3 "<strong>fallback value</strong>" %}
{% endautoescape %}
```

Or if only some variables should be escaped, you can use:

```
{% firstof var1 var2|safe var3 "<strong>fallback value</strong>"|safe %}
```

You can use the syntax `{% firstof var1 var2 var3 as value %}` to store the output inside a variable.

The “as” syntax was added.

## for

Loops over each item in an array, making the item available in a context variable. For example, to display a list of athletes provided in `athlete_list`:

```
<ul>
{% for athlete in athlete_list %}
  <li>{{ athlete.name }}</li>
{% endfor %}
</ul>
```

You can loop over a list in reverse by using `{% for obj in list reversed %}`.

If you need to loop over a list of lists, you can unpack the values in each sublist into individual variables. For example, if your context contains a list of (x,y) coordinates called `points`, you could use the following to output the list of points:

```
{% for x, y in points %}
    There is a point at {{ x }}, {{ y }}
{% endfor %}
```

This can also be useful if you need to access the items in a dictionary. For example, if your context contained a dictionary data, the following would display the keys and values of the dictionary:

```
{% for key, value in data.items %}
    {{ key }}: {{ value }}
{% endfor %}
```

Keep in mind that for the dot operator, dictionary key lookup takes precedence over method lookup. Therefore if the data dictionary contains a key named 'items', `data.items` will return `data['items']` instead of `data.items()`. Avoid adding keys that are named like dictionary methods if you want to use those methods in a template (items, values, keys, etc.). Read more about the lookup order of the dot operator in the [documentation of template variables](#).

The for loop sets a number of variables available within the loop:

Variable	Description
<code>forloop.counter</code>	The current iteration of the loop (1-indexed)
<code>forloop.counter0</code>	The current iteration of the loop (0-indexed)
<code>forloop.revcounter</code>	The number of iterations from the end of the loop (1-indexed)
<code>forloop.revcounter0</code>	The number of iterations from the end of the loop (0-indexed)
<code>forloop.first</code>	True if this is the first time through the loop
<code>forloop.last</code>	True if this is the last time through the loop
<code>forloop.parentloop</code>	For nested loops, this is the loop surrounding the current one

### for ... empty

The for tag can take an optional `{% empty %}` clause whose text is displayed if the given array is empty or could not be found:

```
<ul>
{% for athlete in athlete_list %}
    <li>{{ athlete.name }}</li>
{% empty %}
    <li>Sorry, no athletes in this list.</li>
{% endfor %}
</ul>
```

The above is equivalent to – but shorter, cleaner, and possibly faster than – the following:

```
<ul>
{% if athlete_list %}
    {% for athlete in athlete_list %}
        <li>{{ athlete.name }}</li>
    {% endfor %}
{% else %}
    <li>Sorry, no athletes in this list.</li>
{% endif %}
</ul>
```

## if

The `{% if %}` tag evaluates a variable, and if that variable is “true” (i.e. exists, is not empty, and is not a false boolean value) the contents of the block are output:

```
{% if athlete_list %}
    Number of athletes: {{ athlete_list|length }}
{% elif athlete_in_locker_room_list %}
    Athletes should be out of the locker room soon!
{% else %}
    No athletes.
{% endif %}
```

In the above, if `athlete_list` is not empty, the number of athletes will be displayed by the `{{ athlete_list|length }}` variable.

As you can see, the `if` tag may take one or several `{% elif %}` clauses, as well as an `{% else %}` clause that will be displayed if all previous conditions fail. These clauses are optional.

## Boolean operators

`if` tags may use `and`, `or` or `not` to test a number of variables or to negate a given variable:

```
{% if athlete_list and coach_list %}
    Both athletes and coaches are available.
{% endif %}

{% if not athlete_list %}
    There are no athletes.
{% endif %}

{% if athlete_list or coach_list %}
    There are some athletes or some coaches.
{% endif %}

{% if not athlete_list or coach_list %}
    There are no athletes or there are some coaches.
{% endif %}

{% if athlete_list and not coach_list %}
    There are some athletes and absolutely no coaches.
{% endif %}
```

Use of both `and` and `or` clauses within the same tag is allowed, with `and` having higher precedence than `or` e.g.:

```
{% if athlete_list and coach_list or cheerleader_list %}
```

will be interpreted like:

```
if (athlete_list and coach_list) or cheerleader_list
```

Use of actual parentheses in the `if` tag is invalid syntax. If you need them to indicate precedence, you should use nested `if` tags.

`if` tags may also use the operators `==`, `!=`, `<`, `>`, `<=`, `>=`, `in`, `not in`, `is`, and `is not` which work as follows:

### **== operator**

Equality. Example:

```
{% if somevar == "x" %}
    This appears if variable somevar equals the string "x"
{% endif %}
```

### **!= operator**

Inequality. Example:

```
{% if somevar != "x" %}
    This appears if variable somevar does not equal the string "x",
    or if somevar is not found in the context
{% endif %}
```

### **< operator**

Less than. Example:

```
{% if somevar < 100 %}
    This appears if variable somevar is less than 100.
{% endif %}
```

### **> operator**

Greater than. Example:

```
{% if somevar > 0 %}
    This appears if variable somevar is greater than 0.
{% endif %}
```

### **<= operator**

Less than or equal to. Example:

```
{% if somevar <= 100 %}
    This appears if variable somevar is less than 100 or equal to 100.
{% endif %}
```

### **>= operator**

Greater than or equal to. Example:

```
{% if somevar >= 1 %}
    This appears if variable somevar is greater than 1 or equal to 1.
{% endif %}
```

## in operator

Contained within. This operator is supported by many Python containers to test whether the given value is in the container. The following are some examples of how `x in y` will be interpreted:

```
{% if "bc" in "abcdef" %}
  This appears since "bc" is a substring of "abcdef"
{% endif %}

{% if "hello" in greetings %}
  If greetings is a list or set, one element of which is the string
  "hello", this will appear.
{% endif %}

{% if user in users %}
  If users is a QuerySet, this will appear if user is an
  instance that belongs to the QuerySet.
{% endif %}
```

## not in operator

Not contained within. This is the negation of the `in` operator.

## is operator

Object identity. Tests if two values are the same object. Example:

```
{% if somevar is True %}
  This appears if and only if somevar is True.
{% endif %}

{% if somevar is None %}
  This appears if somevar is None, or if somevar is not found in the context.
{% endif %}
```

## is not operator

Negated object identity. Tests if two values are not the same object. This is the negation of the `is` operator. Example:

```
{% if somevar is not True %}
  This appears if somevar is not True, or if somevar is not found in the
  context.
{% endif %}

{% if somevar is not None %}
  This appears if and only if somevar is not None.
{% endif %}
```

## Filters

You can also use filters in the `if` expression. For example:

```
{% if messages|length >= 100 %}
    You have lots of messages today!
{% endif %}
```

## Complex expressions

All of the above can be combined to form complex expressions. For such expressions, it can be important to know how the operators are grouped when the expression is evaluated - that is, the precedence rules. The precedence of the operators, from lowest to highest, is as follows:

- or
- and
- not
- in
- ==, !=, <, >, <=, >=

(This follows Python exactly). So, for example, the following complex *if* tag:

```
{% if a == b or c == d and e %}
```

...will be interpreted as:

```
(a == b) or ((c == d) and e)
```

If you need different precedence, you will need to use nested *if* tags. Sometimes that is better for clarity anyway, for the sake of those who do not know the precedence rules.

The comparison operators cannot be ‘chained’ like in Python or in mathematical notation. For example, instead of using:

```
{% if a > b > c %} (WRONG)
```

you should use:

```
{% if a > b and b > c %}
```

## ifequal and ifnotequal

`{% ifequal a b %} ... {% endifequal %}` is an obsolete way to write `{% if a == b %} ... {% endif %}`. Likewise, `{% ifnotequal a b %} ... {% endifnotequal %}` is superseded by `{% if a != b %} ... {% endif %}`. The `ifequal` and `ifnotequal` tags will be deprecated in a future release.

## ifchanged

Check if a value has changed from the last iteration of a loop.

The `{% ifchanged %}` block tag is used within a loop. It has two possible uses.

1. Checks its own rendered contents against its previous state and only displays the content if it has changed. For example, this displays a list of days, only displaying the month if it changes:

```
<h1>Archive for {{ year }}</h1>

{% for date in days %}
    {% ifchanged %}<h3>{{ date|date:"F" }}</h3>{% endifchanged %}
    <a href="{{ date|date:"M/d"|lower }}" />{{ date|date:"j" }}</a>
{% endfor %}
```

2. If given one or more variables, check whether any variable has changed. For example, the following shows the date every time it changes, while showing the hour if either the hour or the date has changed:

```
{% for date in days %}
    {% ifchanged date.date %} {{ date.date }} {% endifchanged %}
    {% ifchanged date.hour date.date %}
        {{ date.hour }}
    {% endifchanged %}
{% endfor %}
```

The `ifchanged` tag can also take an optional `{% else %}` clause that will be displayed if the value has not changed:

```
{% for match in matches %}
    <div style="background-color:
        {% ifchanged match.ballot_id %}
            {% cycle "red" "blue" %}
        {% else %}
            gray
        {% endifchanged %}
    ">{{ match }}</div>
{% endfor %}
```

## include

Loads a template and renders it with the current context. This is a way of “including” other templates within a template.

The template name can either be a variable or a hard-coded (quoted) string, in either single or double quotes.

This example includes the contents of the template `"foo/bar.html"`:

```
{% include "foo/bar.html" %}
```

A string argument may be a relative path starting with `./` or `../` as described in the `extends` tag.

The ability to use a relative path was added.

This example includes the contents of the template whose name is contained in the variable `template_name`:

```
{% include template_name %}
```

The variable may also be any object with a `render()` method that accepts a context. This allows you to reference a compiled `Template` in your context.

An included template is rendered within the context of the template that includes it. This example produces the output `"Hello, John!"`:

- Context: variable `person` is set to `"John"` and variable `greeting` is set to `"Hello"`.
- Template:

```
{% include "name_snippet.html" %}
```

- The `name_snippet.html` template:

```
{{ greeting }}, {{ person|default:"friend" }}!
```

You can pass additional context to the template using keyword arguments:

```
{% include "name_snippet.html" with person="Jane" greeting="Hello" %}
```

If you want to render the context only with the variables provided (or even no variables at all), use the `only` option. No other variables are available to the included template:

```
{% include "name_snippet.html" with greeting="Hi" only %}
```

If the included template causes an exception while it's rendered (including if it's missing or has syntax errors), the behavior varies depending on the *template engine's* debug option (if not set, this option defaults to the value of `DEBUG`). When debug mode is turned on, an exception like `TemplateDoesNotExist` or `TemplateSyntaxError` will be raised. When debug mode is turned off, `{% include %}` logs a warning to the `django.template` logger with the exception that happens while rendering the included template and returns an empty string.

Template logging now includes the warning logging mentioned above.

---

**Note:** The `include` tag should be considered as an implementation of “render this subtemplate and include the HTML”, not as “parse this subtemplate and include its contents as if it were part of the parent”. This means that there is no shared state between included templates – each include is a completely independent rendering process.

Blocks are evaluated *before* they are included. This means that a template that includes blocks from another will contain blocks that have *already been evaluated and rendered* - not blocks that can be overridden by, for example, an extending template.

---

## load

Loads a custom template tag set.

For example, the following template would load all the tags and filters registered in `somelibrary` and `otherlibrary` located in package `package`:

```
{% load somelibrary package.otherlibrary %}
```

You can also selectively load individual filters or tags from a library, using the `from` argument. In this example, the template tags/filters named `foo` and `bar` will be loaded from `somelibrary`:

```
{% load foo bar from somelibrary %}
```

See *Custom tag and filter libraries* for more information.

## lorem

Displays random “lorem ipsum” Latin text. This is useful for providing sample data in templates.

Usage:

```
{% lorem [count] [method] [random] %}
```

The `{% lorem %}` tag can be used with zero, one, two or three arguments. The arguments are:

Argument	Description
<code>count</code>	A number (or variable) containing the number of paragraphs or words to generate (default is 1).
<code>method</code>	Either <code>w</code> for words, <code>p</code> for HTML paragraphs or <code>b</code> for plain-text paragraph blocks (default is <code>b</code> ).
<code>random</code>	The word <code>random</code> , which if given, does not use the common paragraph (“Lorem ipsum dolor sit amet...”) when generating text.

Examples:

- `{% lorem %}` will output the common “lorem ipsum” paragraph.
- `{% lorem 3 p %}` will output the common “lorem ipsum” paragraph and two random paragraphs each wrapped in HTML `<p>` tags.
- `{% lorem 2 w random %}` will output two random Latin words.

## now

Displays the current date and/or time, using a format according to the given string. Such string can contain format specifiers characters as described in the [date](#) filter section.

Example:

```
It is {% now "jS F Y H:i" %}
```

Note that you can backslash-escape a format string if you want to use the “raw” value. In this example, both “o” and “f” are backslash-escaped, because otherwise each is a format string that displays the year and the time, respectively:

```
It is the {% now "jS \o\f F" %}
```

This would display as “It is the 4th of September”.

**Note:** The format passed can also be one of the predefined ones `DATE_FORMAT`, `DATETIME_FORMAT`, `SHORT_DATE_FORMAT` or `SHORT_DATETIME_FORMAT`. The predefined formats may vary depending on the current locale and if *Format localization* is enabled, e.g.:

```
It is {% now "SHORT_DATETIME_FORMAT" %}
```

You can also use the syntax `{% now "Y" as current_year %}` to store the output (as a string) inside a variable. This is useful if you want to use `{% now %}` inside a template tag like `blocktrans` for example:

```
{% now "Y" as current_year %}
{% blocktrans %}Copyright {{ current_year }}{% endblocktrans %}
```

## regroup

Regroups a list of alike objects by a common attribute.

This complex tag is best illustrated by way of an example: say that `cities` is a list of cities represented by dictionaries containing “name”, “population”, and “country” keys:

```
cities = [
    {'name': 'Mumbai', 'population': '19,000,000', 'country': 'India'},
    {'name': 'Calcutta', 'population': '15,000,000', 'country': 'India'},
    {'name': 'New York', 'population': '20,000,000', 'country': 'USA'},
    {'name': 'Chicago', 'population': '7,000,000', 'country': 'USA'},
    {'name': 'Tokyo', 'population': '33,000,000', 'country': 'Japan'},
]
```

...and you'd like to display a hierarchical list that is ordered by country, like this:

- India
  - Mumbai: 19,000,000
  - Calcutta: 15,000,000
- USA
  - New York: 20,000,000
  - Chicago: 7,000,000
- Japan
  - Tokyo: 33,000,000

You can use the `{% regroup %}` tag to group the list of cities by country. The following snippet of template code would accomplish this:

```
{% regroup cities by country as country_list %}
<ul>
{% for country in country_list %}
  <li>{{ country.grouper }}
  <ul>
    {% for city in country.list %}
      <li>{{ city.name }}: {{ city.population }}</li>
    {% endfor %}
  </ul>
</li>
{% endfor %}
</ul>
```

Let's walk through this example. `{% regroup %}` takes three arguments: the list you want to regroup, the attribute to group by, and the name of the resulting list. Here, we're regrouping the `cities` list by the `country` attribute and calling the result `country_list`.

`{% regroup %}` produces a list (in this case, `country_list`) of **group objects**. Each group object has two attributes:

- `grouper` – the item that was grouped by (e.g., the string “India” or “Japan”).
- `list` – a list of all items in this group (e.g., a list of all cities with `country='India'`).

Note that `{% regroup %}` does not order its input! Our example relies on the fact that the `cities` list was ordered by `country` in the first place. If the `cities` list did *not* order its members by `country`, the regrouping would naively display more than one group for a single country. For example, say the `cities` list was set to this (note that the countries are not grouped together):

```
cities = [
    {'name': 'Mumbai', 'population': '19,000,000', 'country': 'India'},
    {'name': 'New York', 'population': '20,000,000', 'country': 'USA'},
```

```
[
  {'name': 'Calcutta', 'population': '15,000,000', 'country': 'India'},
  {'name': 'Chicago', 'population': '7,000,000', 'country': 'USA'},
  {'name': 'Tokyo', 'population': '33,000,000', 'country': 'Japan'},
]
```

With this input for `cities`, the example `{% regroup %}` template code above would result in the following output:

- India
  - Mumbai: 19,000,000
- USA
  - New York: 20,000,000
- India
  - Calcutta: 15,000,000
- USA
  - Chicago: 7,000,000
- Japan
  - Tokyo: 33,000,000

The easiest solution to this gotcha is to make sure in your view code that the data is ordered according to how you want to display it.

Another solution is to sort the data in the template using the `dictsort` filter, if your data is in a list of dictionaries:

```
{% regroup cities|dictsort:"country" by country as country_list %}
```

## Grouping on other properties

Any valid template lookup is a legal grouping attribute for the `regroup` tag, including methods, attributes, dictionary keys and list items. For example, if the “country” field is a foreign key to a class with an attribute “description,” you could use:

```
{% regroup cities by country.description as country_list %}
```

Or, if `country` is a field with `choices`, it will have a `get_FOO_display()` method available as an attribute, allowing you to group on the display string rather than the `choices` key:

```
{% regroup cities by get_country_display as country_list %}
```

`{{ country.grouper }}` will now display the value fields from the `choices` set rather than the keys.

## spaceless

Removes whitespace between HTML tags. This includes tab characters and newlines.

Example usage:

```
{% spaceless %}
  <p>
    <a href="foo/">Foo</a>
  </p>
{% endspaceless %}
```

This example would return this HTML:

```
<p><a href="foo/">Foo</a></p>
```

Only space between *tags* is removed – not space between tags and text. In this example, the space around Hello won't be stripped:

```
{% spaceless %}
  <strong>
    Hello
  </strong>
{% endspaceless %}
```

## templatetag

Outputs one of the syntax characters used to compose template tags.

Since the template system has no concept of “escaping”, to display one of the bits used in template tags, you must use the `{% templatetag %}` tag.

The argument tells which template bit to output:

Argument	Outputs
openblock	{%
closeblock	%}
openvariable	{{
closevariable	}}
openbrace	{
closebrace	}
opencomment	{#
closecomment	#}

Sample usage:

```
{% templatetag openblock %} url 'entry_list' {% templatetag closeblock %}
```

## url

Returns an absolute path reference (a URL without the domain name) matching a given view and optional parameters. Any special characters in the resulting path will be encoded using `iri_to_uri()`.

This is a way to output links without violating the DRY principle by having to hard-code URLs in your templates:

```
{% url 'some-url-name' v1 v2 %}
```

The first argument is a `url()` name. It can be a quoted literal or any other context variable. Additional arguments are optional and should be space-separated values that will be used as arguments in the URL. The example above shows passing positional arguments. Alternatively you may use keyword syntax:

```
{% url 'some-url-name' arg1=v1 arg2=v2 %}
```

Do not mix both positional and keyword syntax in a single call. All arguments required by the URLconf should be present.

For example, suppose you have a view, `app_views.client`, whose URLconf takes a client ID (here, `client()` is a method inside the views file `app_views.py`). The URLconf line might look like this:

```
('^client/([0-9]+)/$', app_views.client, name='app-views-client')
```

If this app's URLconf is included into the project's URLconf under a path such as this:

```
('^clients/', include('project_name.app_name.urls'))
```

...then, in a template, you can create a link to this view like this:

```
{% url 'app-views-client' client.id %}
```

The template tag will output the string `/clients/client/123/`.

Note that if the URL you're reversing doesn't exist, you'll get an `NoReverseMatch` exception raised, which will cause your site to display an error page.

If you'd like to retrieve a URL without displaying it, you can use a slightly different call:

```
{% url 'some-url-name' arg arg2 as the_url %}
<a href="{{ the_url }}">I'm linking to {{ the_url }}</a>
```

The scope of the variable created by the `as var` syntax is the `{% block %}` in which the `{% url %}` tag appears.

This `{% url ... as var %}` syntax will *not* cause an error if the view is missing. In practice you'll use this to link to views that are optional:

```
{% url 'some-url-name' as the_url %}
{% if the_url %}
  <a href="{{ the_url }}">Link to optional stuff</a>
{% endif %}
```

If you'd like to retrieve a namespaced URL, specify the fully qualified name:

```
{% url 'myapp:view-name' %}
```

This will follow the normal *namespaced URL resolution strategy*, including using any hints provided by the context as to the current application.

**Warning:** Don't forget to put quotes around the `url()` name, otherwise the value will be interpreted as a context variable!

## verbatim

Stops the template engine from rendering the contents of this block tag.

A common use is to allow a JavaScript template layer that collides with Django's syntax. For example:

```
{% verbatim %}
  {{if dying}}Still alive.{{/if}}
{% endverbatim %}
```

You can also designate a specific closing tag, allowing the use of `{% endverbatim %}` as part of the unrendered contents:

```
{% verbatim myblock %}
  Avoid template rendering via the {% verbatim %}{% endverbatim %} block.
{% endverbatim myblock %}
```

## widthratio

For creating bar charts and such, this tag calculates the ratio of a given value to a maximum value, and then applies that ratio to a constant.

For example:

```

```

If `this_value` is 175, `max_value` is 200, and `max_width` is 100, the image in the above example will be 88 pixels wide (because  $175/200 = .875$ ;  $.875 * 100 = 87.5$  which is rounded up to 88).

In some cases you might want to capture the result of `widthratio` in a variable. It can be useful, for instance, in a `blocktrans` like this:

```
{% widthratio this_value max_value max_width as width %}
{% blocktrans %}The width is: {{ width }}{% endblocktrans %}
```

## with

Caches a complex variable under a simpler name. This is useful when accessing an “expensive” method (e.g., one that hits the database) multiple times.

For example:

```
{% with total=business.employees.count %}
  {{ total }} employee{{ total|pluralize }}
{% endwith %}
```

The populated variable (in the example above, `total`) is only available between the `{% with %}` and `{% endwith %}` tags.

You can assign more than one context variable:

```
{% with alpha=1 beta=2 %}
  ...
{% endwith %}
```

---

**Note:** The previous more verbose format is still supported: `{% with business.employees.count as total %}`

---

## Built-in filter reference

### add

Adds the argument to the value.

For example:

```
{{ value|add:"2" }}
```

If `value` is 4, then the output will be 6.

This filter will first try to coerce both values to integers. If this fails, it'll attempt to add the values together anyway. This will work on some data types (strings, list, etc.) and fail on others. If it fails, the result will be an empty string.

For example, if we have:

```
{{ first|add:second }}
```

and `first` is [1, 2, 3] and `second` is [4, 5, 6], then the output will be [1, 2, 3, 4, 5, 6].

**Warning:** Strings that can be coerced to integers will be **summed**, not concatenated, as in the first example above.

### addslashes

Adds slashes before quotes. Useful for escaping strings in CSV, for example.

For example:

```
{{ value|addslashes }}
```

If `value` is "I'm using Django", the output will be "I\'m using Django".

### capfirst

Capitalizes the first character of the value. If the first character is not a letter, this filter has no effect.

For example:

```
{{ value|capfirst }}
```

If `value` is "django", the output will be "Django".

### center

Centers the value in a field of a given width.

For example:

```
"{{ value|center:"15" }}"
```

If `value` is "Django", the output will be " Django ".

## cut

Removes all values of arg from the given string.

For example:

```
{{ value|cut:" " }}
```

If value is "String with spaces", the output will be "Stringwithspaces".

## date

Formats a date according to the given format.

Uses a similar format as PHP's `date()` function (<https://php.net/date>) with some differences.

---

**Note:** These format characters are not used in Django outside of templates. They were designed to be compatible with PHP to ease transitioning for designers.

---

Available format strings:

Format character	Description
a	'a.m.' or 'p.m.' (Note that this is slightly different than PHP's output, because this includes periods to match the locale.)
A	'AM' or 'PM'.
b	Month, textual, 3 letters, lowercase.
B	Not implemented.
c	ISO 8601 format. (Note: unlike others formatters, such as "Z", "O" or "r", the "c" formatter will not add timezone information.)
d	Day of the month, 2 digits with leading zeros.
D	Day of the week, textual, 3 letters.
e	Timezone name. Could be in any format, or might return an empty string, depending on the datetime.
E	Month, locale specific alternative representation usually used for long date representation.
f	Time, in 12-hour hours and minutes, with minutes left off if they're zero. Proprietary extension.
F	Month, textual, long.
g	Hour, 12-hour format without leading zeros.
G	Hour, 24-hour format without leading zeros.
h	Hour, 12-hour format.
H	Hour, 24-hour format.
i	Minutes.
I	Daylight Savings Time, whether it's in effect or not.
j	Day of the month without leading zeros.
l	Day of the week, textual, long.
L	Boolean for whether it's a leap year.
m	Month, 2 digits with leading zeros.
M	Month, textual, 3 letters.
n	Month without leading zeros.
N	Month abbreviation in Associated Press style. Proprietary extension.
o	ISO-8601 week-numbering year, corresponding to the ISO-8601 week number (W) which uses leap weeks. See <a href="#">ISO 8601</a> .
O	Difference to Greenwich time in hours.
P	Time, in 12-hour hours, minutes and 'a.m.?'/'p.m.', with minutes left off if they're zero and the special-case string 'noon'/'midnight'.
r	<a href="#">RFC 5322</a> formatted date.
s	Seconds, 2 digits with leading zeros.

Format character	Description
S	English ordinal suffix for day of the month, 2 characters.
t	Number of days in the given month.
T	Time zone of this machine.
u	Microseconds.
U	Seconds since the Unix Epoch (January 1 1970 00:00:00 UTC).
w	Day of the week, digits without leading zeros.
W	ISO-8601 week number of year, with weeks starting on Monday.
y	Year, 2 digits.
Y	Year, 4 digits.
z	Day of the year.
Z	Time zone offset in seconds. The offset for timezones west of UTC is always negative, and for those east of UTC

For example:

```
{{ value|date:"D d M Y" }}
```

If `value` is a `datetime` object (e.g., the result of `datetime.datetime.now()`), the output will be the string `'Wed 09 Jan 2008'`.

The format passed can be one of the predefined ones `DATE_FORMAT`, `DATETIME_FORMAT`, `SHORT_DATE_FORMAT` or `SHORT_DATETIME_FORMAT`, or a custom format that uses the format specifiers shown in the table above. Note that predefined formats may vary depending on the current locale.

Assuming that `USE_L10N` is `True` and `LANGUAGE_CODE` is, for example, `"es"`, then for:

```
{{ value|date:"SHORT_DATE_FORMAT" }}
```

the output would be the string `"09/01/2008"` (the `"SHORT_DATE_FORMAT"` format specifier for the `es` locale as shipped with Django is `"d/m/Y"`).

When used without a format string, the `DATE_FORMAT` format specifier is used. Assuming the same settings as the previous example:

```
{{ value|date }}
```

outputs `9 de Enero de 2008` (the `DATE_FORMAT` format specifier for the `es` locale is `r'j \d\e F \d\e Y'`).

In older versions, the `DATE_FORMAT` setting (without localization) is always used when a format string isn't given.

You can combine `date` with the `time` filter to render a full representation of a `datetime` value. E.g.:

```
{{ value|date:"D d M Y" }} {{ value|time:"H:i" }}
```

### default

If `value` evaluates to `False`, uses the given default. Otherwise, uses the value.

For example:

```
{{ value|default:"nothing" }}
```

If `value` is `" "` (the empty string), the output will be `nothing`.

### default\_if\_none

If (and only if) value is `None`, uses the given default. Otherwise, uses the value.

Note that if an empty string is given, the default value will *not* be used. Use the `default` filter if you want to fallback for empty strings.

For example:

```
{{ value|default_if_none:"nothing" }}
```

If value is `None`, the output will be the string "nothing".

### dictsort

Takes a list of dictionaries and returns that list sorted by the key given in the argument.

For example:

```
{{ value|dictsort:"name" }}
```

If value is:

```
[
  {'name': 'zed', 'age': 19},
  {'name': 'amy', 'age': 22},
  {'name': 'joe', 'age': 31},
]
```

then the output would be:

```
[
  {'name': 'amy', 'age': 22},
  {'name': 'joe', 'age': 31},
  {'name': 'zed', 'age': 19},
]
```

You can also do more complicated things like:

```
{% for book in books|dictsort:"author.age" %}
  * {{ book.title }} ({{ book.author.name }})
{% endfor %}
```

If books is:

```
[
  {'title': '1984', 'author': {'name': 'George', 'age': 45}},
  {'title': 'Timequake', 'author': {'name': 'Kurt', 'age': 75}},
  {'title': 'Alice', 'author': {'name': 'Lewis', 'age': 33}},
]
```

then the output would be:

```
* Alice (Lewis)
* 1984 (George)
* Timequake (Kurt)
```

`dictsort` can also order a list of lists (or any other object implementing `__getitem__()`) by elements at specified index. For example:

```
{{ value|dictsort:0 }}
```

If `value` is:

```
[
    ('a', '42'),
    ('c', 'string'),
    ('b', 'foo'),
]
```

then the output would be:

```
[
    ('a', '42'),
    ('b', 'foo'),
    ('c', 'string'),
]
```

You must pass the index as an integer rather than a string. The following produce empty output:

```
{{ values|dictsort:"0" }}
```

The ability to order a list of lists was added.

### `dictsortreversed`

Takes a list of dictionaries and returns that list sorted in reverse order by the key given in the argument. This works exactly the same as the above filter, but the returned value will be in reverse order.

### `divisibleby`

Returns `True` if the value is divisible by the argument.

For example:

```
{{ value|divisibleby:"3" }}
```

If `value` is 21, the output would be `True`.

### `escape`

Escapes a string's HTML. Specifically, it makes these replacements:

- `<` is converted to `&lt;`;
- `>` is converted to `&gt;`;
- `'` (single quote) is converted to `&#39;`;
- `"` (double quote) is converted to `&quot;`;
- `&` is converted to `&amp;`;

The escaping is only applied when the string is output, so it does not matter where in a chained sequence of filters you put `escape`: it will always be applied as though it were the last filter. If you want escaping to be applied immediately, use the `force_escape` filter.

Applying `escape` to a variable that would normally have auto-escaping applied to the result will only result in one round of escaping being done. So it is safe to use this function even in auto-escaping environments. If you want multiple escaping passes to be applied, use the `force_escape` filter.

For example, you can apply `escape` to fields when `autoescape` is off:

```
{% autoescape off %}
  {{ title|escape }}
{% endautoescape %}
```

Deprecated since version 1.10: The “lazy” behavior of the `escape` filter is deprecated. It will change to immediately apply `conditional_escape()` in Django 2.0.

### `escapejs`

Escapes characters for use in JavaScript strings. This does *not* make the string safe for use in HTML, but does protect you from syntax errors when using templates to generate JavaScript/JSON.

For example:

```
{{ value|escapejs }}
```

If `value` is `"testing\r\njavascript \'string" <b>escaping</b>"`, the output will be `"testing\\u000D\\u000Ajavascript \\u0027string\\u0022\\u003Cb\\u003Eescaping\\u003C/b\\u003E"`.

### `filesizeformat`

Formats the value like a ‘human-readable’ file size (i.e. `'13 KB'`, `'4.1 MB'`, `'102 bytes'`, etc.).

For example:

```
{{ value|filesizeformat }}
```

If `value` is `123456789`, the output would be `117.7 MB`.

---

### File sizes and SI units

Strictly speaking, `filesizeformat` does not conform to the International System of Units which recommends using KiB, MiB, GiB, etc. when byte sizes are calculated in powers of 1024 (which is the case here). Instead, Django uses traditional unit names (KB, MB, GB, etc.) corresponding to names that are more commonly used.

---

### `first`

Returns the first item in a list.

For example:

```
{{ value|first }}
```

If `value` is the list `['a', 'b', 'c']`, the output will be `'a'`.

### `floatformat`

When used without an argument, rounds a floating-point number to one decimal place – but only if there’s a decimal part to be displayed. For example:

value	Template	Output
34.23234	<code>{{ value floatformat }}</code>	34.2
34.00000	<code>{{ value floatformat }}</code>	34
34.26000	<code>{{ value floatformat }}</code>	34.3

If used with a numeric integer argument, `floatformat` rounds a number to that many decimal places. For example:

value	Template	Output
34.23234	<code>{{ value floatformat:3 }}</code>	34.232
34.00000	<code>{{ value floatformat:3 }}</code>	34.000
34.26000	<code>{{ value floatformat:3 }}</code>	34.260

Particularly useful is passing 0 (zero) as the argument which will round the float to the nearest integer.

value	Template	Output
34.23234	<code>{{ value floatformat:"0" }}</code>	34
34.00000	<code>{{ value floatformat:"0" }}</code>	34
39.56000	<code>{{ value floatformat:"0" }}</code>	40

If the argument passed to `floatformat` is negative, it will round a number to that many decimal places – but only if there’s a decimal part to be displayed. For example:

value	Template	Output
34.23234	<code>{{ value floatformat:"-3" }}</code>	34.232
34.00000	<code>{{ value floatformat:"-3" }}</code>	34
34.26000	<code>{{ value floatformat:"-3" }}</code>	34.260

Using `floatformat` with no argument is equivalent to using `floatformat` with an argument of `-1`.

### `force_escape`

Applies HTML escaping to a string (see the `escape` filter for details). This filter is applied *immediately* and returns a new, escaped string. This is useful in the rare cases where you need multiple escaping or want to apply other filters to the escaped results. Normally, you want to use the `escape` filter.

For example, if you want to catch the `<p>` HTML elements created by the `linebreaks` filter:

```
{% autoescape off %}
  {{ body|linebreaks|force_escape }}
{% endautoescape %}
```

### `get_digit`

Given a whole number, returns the requested digit, where 1 is the right-most digit, 2 is the second-right-most digit, etc. Returns the original value for invalid input (if input or argument is not an integer, or if argument is less than 1). Otherwise, output is always an integer.

For example:

```
{{ value|get_digit:"2" }}
```

If `value` is `123456789`, the output will be `8`.

### **iriencode**

Converts an IRI (Internationalized Resource Identifier) to a string that is suitable for including in a URL. This is necessary if you're trying to use strings containing non-ASCII characters in a URL.

It's safe to use this filter on a string that has already gone through the `urlencode` filter.

For example:

```
{{ value|iriencode }}
```

If `value` is `"?test=1&me=2"`, the output will be `"?test=1&me=2"`.

### **join**

Joins a list with a string, like Python's `str.join(list)`

For example:

```
{{ value|join:" // " }}
```

If `value` is the list `['a', 'b', 'c']`, the output will be the string `"a // b // c"`.

### **last**

Returns the last item in a list.

For example:

```
{{ value|last }}
```

If `value` is the list `['a', 'b', 'c', 'd']`, the output will be the string `"d"`.

### **length**

Returns the length of the value. This works for both strings and lists.

For example:

```
{{ value|length }}
```

If `value` is `['a', 'b', 'c', 'd']` or `"abcd"`, the output will be `4`.

The filter returns `0` for an undefined variable.

### `length_is`

Returns `True` if the value's length is the argument, or `False` otherwise.

For example:

```
{{ value|length_is:"4" }}
```

If value is `['a', 'b', 'c', 'd']` or `"abcd"`, the output will be `True`.

### `linebreaks`

Replaces line breaks in plain text with appropriate HTML; a single newline becomes an HTML line break (`<br />`) and a new line followed by a blank line becomes a paragraph break (`</p>`).

For example:

```
{{ value|linebreaks }}
```

If value is `Joel\nis a slug`, the output will be `<p>Joel<br />is a slug</p>`.

### `linebreaksbr`

Converts all newlines in a piece of plain text to HTML line breaks (`<br />`).

For example:

```
{{ value|linebreaksbr }}
```

If value is `Joel\nis a slug`, the output will be `Joel<br />is a slug`.

### `linenumbers`

Displays text with line numbers.

For example:

```
{{ value|linenumbers }}
```

If value is:

```
one  
two  
three
```

the output will be:

```
1. one  
2. two  
3. three
```

### **ljust**

Left-aligns the value in a field of a given width.

**Argument:** field size

For example:

```
"{{ value|ljust:"10" }}"
```

If value is Django, the output will be "Django ".

### **lower**

Converts a string into all lowercase.

For example:

```
{{ value|lower }}
```

If value is Totally LOVING this Album!, the output will be totally loving this album!.

### **make\_list**

Returns the value turned into a list. For a string, it's a list of characters. For an integer, the argument is cast into an unicode string before creating a list.

For example:

```
{{ value|make_list }}
```

If value is the string "Joel", the output would be the list ['J', 'o', 'e', 'l']. If value is 123, the output will be the list ['1', '2', '3'].

### **phone2numeric**

Converts a phone number (possibly containing letters) to its numerical equivalent.

The input doesn't have to be a valid phone number. This will happily convert any string.

For example:

```
{{ value|phone2numeric }}
```

If value is 800-COLLECT, the output will be 800-2655328.

### **pluralize**

Returns a plural suffix if the value is not 1. By default, this suffix is 's'.

Example:

```
You have {{ num_messages }} message{{ num_messages|pluralize }}.
```

If `num_messages` is 1, the output will be `You have 1 message`. If `num_messages` is 2 the output will be `You have 2 messages`.

For words that require a suffix other than `'s'`, you can provide an alternate suffix as a parameter to the filter.

Example:

```
You have {{ num_walruses }} walrus{{ num_walruses|pluralize:"es" }}.
```

For words that don't pluralize by simple suffix, you can specify both a singular and plural suffix, separated by a comma.

Example:

```
You have {{ num_cherries }} cherr{{ num_cherries|pluralize:"y,ies" }}.
```

---

**Note:** Use `blocktrans` to pluralize translated strings.

---

### **pprint**

A wrapper around `pprint.pprint()` – for debugging, really.

### **random**

Returns a random item from the given list.

For example:

```
{{ value|random }}
```

If `value` is the list `['a', 'b', 'c', 'd']`, the output could be `"b"`.

### **rjust**

Right-aligns the value in a field of a given width.

**Argument:** field size

For example:

```
"{{ value|rjust:"10" }}"
```

If `value` is `Django`, the output will be `" Django"`.

### **safe**

Marks a string as not requiring further HTML escaping prior to output. When autoescaping is off, this filter has no effect.

---

**Note:** If you are chaining filters, a filter applied after `safe` can make the contents unsafe again. For example, the following code prints the variable as is, unescaped:

```
{{ var|safe|escape }}
```

### safeseq

Applies the *safe* filter to each element of a sequence. Useful in conjunction with other filters that operate on sequences, such as *join*. For example:

```
{{ some_list|safeseq|join:", " }}
```

You couldn't use the *safe* filter directly in this case, as it would first convert the variable into a string, rather than working with the individual elements of the sequence.

### slice

Returns a slice of the list.

Uses the same syntax as Python's list slicing. See <http://www.diveintopython3.net/native-datatypes.html#slicinglists> for an introduction.

Example:

```
{{ some_list|slice":2" }}
```

If `some_list` is `['a', 'b', 'c']`, the output will be `['a', 'b']`.

### slugify

Converts to ASCII. Converts spaces to hyphens. Removes characters that aren't alphanumerics, underscores, or hyphens. Converts to lowercase. Also strips leading and trailing whitespace.

For example:

```
{{ value|slugify }}
```

If `value` is `"Joel is a slug"`, the output will be `"joel-is-a-slug"`.

### stringformat

Formats the variable according to the argument, a string formatting specifier. This specifier uses the [printf-style String Formatting](#) syntax, with the exception that the leading `"%"` is dropped.

For example:

```
{{ value|stringformat:"E" }}
```

If `value` is `10`, the output will be `1.000000E+01`.

## striptags

Makes all possible efforts to strip all [X]HTML tags.

For example:

```
{{ value|striptags }}
```

If value is "`<b>Joel</b> <button>is</button> a <span>slug</span>`", the output will be "Joel is a slug".

### No safety guarantee

Note that `striptags` doesn't give any guarantee about its output being HTML safe, particularly with non valid HTML input. So **NEVER** apply the `safe` filter to a `striptags` output. If you are looking for something more robust, you can use the `bleach` Python library, notably its `clean` method.

## time

Formats a time according to the given format.

Given format can be the predefined one `TIME_FORMAT`, or a custom format, same as the `date` filter. Note that the predefined format is locale-dependent.

For example:

```
{{ value|time:"H:i" }}
```

If value is equivalent to `datetime.datetime.now()`, the output will be the string "01:23".

Another example:

Assuming that `USE_L10N` is True and `LANGUAGE_CODE` is, for example, "de", then for:

```
{{ value|time:"TIME_FORMAT" }}
```

the output will be the string "01:23:00" (The "TIME\_FORMAT" format specifier for the de locale as shipped with Django is "H:i:s").

The `time` filter will only accept parameters in the format string that relate to the time of day, not the date (for obvious reasons). If you need to format a `date` value, use the `date` filter instead (or along `time` if you need to render a full `datetime` value).

There is one exception the above rule: When passed a `datetime` value with attached timezone information (a *time-zone-aware* `datetime` instance) the `time` filter will accept the timezone-related *format specifiers* 'e', 'O', 'T' and 'Z'.

When used without a format string, the `TIME_FORMAT` format specifier is used:

```
{{ value|time }}
```

is the same as:

```
{{ value|time:"TIME_FORMAT" }}
```

In older versions, the `TIME_FORMAT` setting (without localization) is always used when a format string isn't given.

### timesince

Formats a date as the time since that date (e.g., “4 days, 6 hours”).

Takes an optional argument that is a variable containing the date to use as the comparison point (without the argument, the comparison point is *now*). For example, if `blog_date` is a date instance representing midnight on 1 June 2006, and `comment_date` is a date instance for 08:00 on 1 June 2006, then the following would return “8 hours”:

```
{{ blog_date|timesince:comment_date }}
```

Comparing offset-naive and offset-aware datetimes will return an empty string.

Minutes is the smallest unit used, and “0 minutes” will be returned for any date that is in the future relative to the comparison point.

### timeuntil

Similar to `timesince`, except that it measures the time from now until the given date or datetime. For example, if today is 1 June 2006 and `conference_date` is a date instance holding 29 June 2006, then `{{ conference_date|timeuntil }}` will return “4 weeks”.

Takes an optional argument that is a variable containing the date to use as the comparison point (instead of *now*). If `from_date` contains 22 June 2006, then the following will return “1 week”:

```
{{ conference_date|timeuntil:from_date }}
```

Comparing offset-naive and offset-aware datetimes will return an empty string.

Minutes is the smallest unit used, and “0 minutes” will be returned for any date that is in the past relative to the comparison point.

### title

Converts a string into titlecase by making words start with an uppercase character and the remaining characters lowercase. This tag makes no effort to keep “trivial words” in lowercase.

For example:

```
{{ value|title }}
```

If `value` is “my FIRST post”, the output will be “My First Post”.

### truncatechars

Truncates a string if it is longer than the specified number of characters. Truncated strings will end with a translatable ellipsis sequence (“…”).

**Argument:** Number of characters to truncate to

For example:

```
{{ value|truncatechars:9 }}
```

If `value` is “Joel is a slug”, the output will be “Joel i…”.

### `truncatechars_html`

Similar to `truncatechars`, except that it is aware of HTML tags. Any tags that are opened in the string and not closed before the truncation point are closed immediately after the truncation.

For example:

```
{{ value|truncatechars_html:9 }}
```

If value is "`<p>Joel is a slug</p>`", the output will be "`<p>Joel i...</p>`".

Newlines in the HTML content will be preserved.

### `truncatewords`

Truncates a string after a certain number of words.

**Argument:** Number of words to truncate after

For example:

```
{{ value|truncatewords:2 }}
```

If value is "Joel is a slug", the output will be "Joel is ...".

Newlines within the string will be removed.

### `truncatewords_html`

Similar to `truncatewords`, except that it is aware of HTML tags. Any tags that are opened in the string and not closed before the truncation point, are closed immediately after the truncation.

This is less efficient than `truncatewords`, so should only be used when it is being passed HTML text.

For example:

```
{{ value|truncatewords_html:2 }}
```

If value is "`<p>Joel is a slug</p>`", the output will be "`<p>Joel is ...</p>`".

Newlines in the HTML content will be preserved.

### `unordered_list`

Recursively takes a self-nested list and returns an HTML unordered list – WITHOUT opening and closing `<ul>` tags.

The list is assumed to be in the proper format. For example, if `var` contains `['States', ['Kansas', ['Lawrence', 'Topeka'], 'Illinois']]`, then `{{ var|unordered_list }}` would return:

```
<li>States
<ul>
  <li>Kansas
  <ul>
    <li>Lawrence</li>
    <li>Topeka</li>
  </ul>
</ul>
</li>
```

```
<li>Illinois</li>
</ul>
</li>
```

### upper

Converts a string into all uppercase.

For example:

```
{{ value|upper }}
```

If value is "Joel is a slug", the output will be "JOEL IS A SLUG".

### urlencode

Escapes a value for use in a URL.

For example:

```
{{ value|urlencode }}
```

If value is "https://www.example.org/foo?a=b&c=d", the output will be "https%3A//www.example.org/foo%3Fa%3Db%26c%3Dd".

An optional argument containing the characters which should not be escaped can be provided.

If not provided, the '/' character is assumed safe. An empty string can be provided when *all* characters should be escaped. For example:

```
{{ value|urlencode:"" }}
```

If value is "https://www.example.org/", the output will be "https%3A%2F%2Fwww.example.org%2F".

### urlize

Converts URLs and email addresses in text into clickable links.

This template tag works on links prefixed with `http://`, `https://`, or `www..` For example, `https://goo.gl/aiaIt` will get converted but `goo.gl/aiaIt` won't.

It also supports domain-only links ending in one of the original top level domains (`.com`, `.edu`, `.gov`, `.int`, `.mil`, `.net`, and `.org`). For example, `django project . com` gets converted.

Links can have trailing punctuation (periods, commas, close-parens) and leading punctuation (opening parens), and `urlize` will still do the right thing.

Links generated by `urlize` have a `rel="nofollow"` attribute added to them.

For example:

```
{{ value|urlize }}
```

If `value` is "Check out [www.djangoproject.com](http://www.djangoproject.com)", the output will be "Check out [www.djangoproject.com](http://www.djangoproject.com)".

In addition to web links, `urlize` also converts email addresses into `mailto:` links. If `value` is "Send questions to [foo@example.com](mailto:foo@example.com)", the output will be "Send questions to [foo@example.com](mailto:foo@example.com)".

The `urlize` filter also takes an optional parameter `autoescape`. If `autoescape` is `True`, the link text and URLs will be escaped using Django's built-in `escape` filter. The default value for `autoescape` is `True`.

---

**Note:** If `urlize` is applied to text that already contains HTML markup, things won't work as expected. Apply this filter only to plain text.

---

### `urlizetrunc`

Converts URLs and email addresses into clickable links just like `urlize`, but truncates URLs longer than the given character limit.

**Argument:** Number of characters that link text should be truncated to, including the ellipsis that's added if truncation is necessary.

For example:

```
{{ value|urlizetrunc:15 }}
```

If `value` is "Check out [www.djangoproject.com](http://www.djangoproject.com)", the output would be "Check out [www.djangopr...</a>".](http://www.djangoproject.com)

As with `urlize`, this filter should only be applied to plain text.

### `wordcount`

Returns the number of words.

For example:

```
{{ value|wordcount }}
```

If `value` is "Joel is a slug", the output will be 4.

### `wordwrap`

Wraps words at specified line length.

**Argument:** number of characters at which to wrap the text

For example:

```
{{ value|wordwrap:5 }}
```

If `value` is "Joel is a slug", the output would be:

```
Joel
is a
slug
```

## yesno

Maps values for `True`, `False`, and (optionally) `None`, to the strings “yes”, “no”, “maybe”, or a custom mapping passed as a comma-separated list, and returns one of those strings according to the value:

For example:

```
{{ value|yesno:"yeah,no,maybe" }}
```

Value	Argument	Outputs
<code>True</code>		yes
<code>True</code>	<code>"yeah,no,maybe"</code>	yeah
<code>False</code>	<code>"yeah,no,maybe"</code>	no
<code>None</code>	<code>"yeah,no,maybe"</code>	maybe
<code>None</code>	<code>"yeah,no"</code>	no (converts <code>None</code> to <code>False</code> if no mapping for <code>None</code> is given)

## Internationalization tags and filters

Django provides template tags and filters to control each aspect of *internationalization* in templates. They allow for granular control of translations, formatting, and time zone conversions.

### i18n

This library allows specifying translatable text in templates. To enable it, set `USE_I18N` to `True`, then load it with `{% load i18n %}`.

See *Internationalization: in template code*.

### l10n

This library provides control over the localization of values in templates. You only need to load the library using `{% load l10n %}`, but you’ll often set `USE_L10N` to `True` so that localization is active by default.

See *Controlling localization in templates*.

### tz

This library provides control over time zone conversions in templates. Like `l10n`, you only need to load the library using `{% load tz %}`, but you’ll usually also set `USE_TZ` to `True` so that conversion to local time happens by default.

See *Time zone aware output in templates*.

## Other tags and filters libraries

Django comes with a couple of other template-tag libraries that you have to enable explicitly in your `INSTALLED_APPS` setting and enable in your template with the `{% load %}` tag.

### `django.contrib.humanize`

A set of Django template filters useful for adding a “human touch” to data. See *django.contrib.humanize*.

## static

## static

To link to static files that are saved in `STATIC_ROOT` Django ships with a `static` template tag. If the `django.contrib.staticfiles` app is installed, the tag will serve files using `url()` method of the storage specified by `STATICFILES_STORAGE`. For example:

```
{% load static %}

```

It is also able to consume standard context variables, e.g. assuming a `user_stylesheet` variable is passed to the template:

```
{% load static %}
<link rel="stylesheet" href="{% static user_stylesheet %}" type="text/css" media=
  →"screen" />
```

If you'd like to retrieve a static URL without displaying it, you can use a slightly different call:

```
{% load static %}
{% static "images/hi.jpg" as myphoto %}
</img>
```

## Using Jinja2 templates?

See *Jinja2* for information on using the `static` tag with Jinja2.

In older versions, you had to use `{% load static from staticfiles %}` in your template to serve files from the storage defined in `STATICFILES_STORAGE`. This is no longer required.

## get\_static\_prefix

You should prefer the `static` template tag, but if you need more control over exactly where and how `STATIC_URL` is injected into the template, you can use the `get_static_prefix` template tag:

```
{% load static %}

```

There's also a second form you can use to avoid extra processing if you need the value multiple times:

```
{% load static %}
{% get_static_prefix as STATIC_PREFIX %}

```

## get\_media\_prefix

Similar to the `get_static_prefix`, `get_media_prefix` populates a template variable with the media prefix `MEDIA_URL`, e.g.:

```
{% load static %}
<body data-media-url="{% get_media_prefix %}">
```

By storing the value in a data attribute, we ensure it's escaped appropriately if we want to use it in a JavaScript context.

### 6.20.3 The Django template language: for Python programmers

This document explains the Django template system from a technical perspective – how it works and how to extend it. If you're just looking for reference on the language syntax, see *The Django template language*.

It assumes an understanding of templates, contexts, variables, tags, and rendering. Start with the *introduction to the Django template language* if you aren't familiar with these concepts.

#### Overview

Using the template system in Python is a three-step process:

1. You configure an *Engine*.
2. You compile template code into a *Template*.
3. You render the template with a *Context*.

Django projects generally rely on the *high level, backend agnostic APIs* for each of these steps instead of the template system's lower level APIs:

1. For each *DjangoTemplates* backend in the *TEMPLATES* setting, Django instantiates an *Engine*. *DjangoTemplates* wraps *Engine* and adapts it to the common template backend API.
2. The *django.template.loader* module provides functions such as *get\_template()* for loading templates. They return a *django.template.backends.django.Template* which wraps the actual *django.template.Template*.
3. The *Template* obtained in the previous step has a *render()* method which marshals a context and possibly a request into a *Context* and delegates the rendering to the underlying *Template*.

#### Configuring an engine

If you are simply using the *DjangoTemplates* backend, this probably isn't the documentation you're looking for. An instance of the *Engine* class described below is accessible using the *engine* attribute of that backend and any attribute defaults mentioned below are overridden by what's passed by *DjangoTemplates*.

```
class Engine(dirs=None, app_dirs=False, context_processors=None, debug=False, loaders=None,
             string_if_invalid='', file_charset='utf-8', libraries=None, builtins=None, autoescape=True)
```

When instantiating an *Engine* all arguments must be passed as keyword arguments:

- *dirs* is a list of directories where the engine should look for template source files. It is used to configure *filesystem.Loader*.

It defaults to an empty list.

- *app\_dirs* only affects the default value of *loaders*. See below.

It defaults to *False*.

- *autoescape* controls whether HTML autoescaping is enabled.

It defaults to *True*.

**Warning:** Only set it to `False` if you're rendering non-HTML templates!

The `autoescape` option was added.

- `context_processors` is a list of dotted Python paths to callables that are used to populate the context when a template is rendered with a request. These callables take a request object as their argument and return a `dict` of items to be merged into the context.

It defaults to an empty list.

See [RequestContext](#) for more information.

- `debug` is a boolean that turns on/off template debug mode. If it is `True`, the template engine will store additional debug information which can be used to display a detailed report for any exception raised during template rendering.

It defaults to `False`.

- `loaders` is a list of template loader classes, specified as strings. Each `Loader` class knows how to import templates from a particular source. Optionally, a tuple can be used instead of a string. The first item in the tuple should be the `Loader` class name, subsequent items are passed to the `Loader` during initialization.

It defaults to a list containing:

- `'django.template.loaders.filesystem.Loader'`
- `'django.template.loaders.app_directories.Loader'` if and only if `app_dirs` is `True`.

See [Loader types](#) for details.

- `string_if_invalid` is the output, as a string, that the template system should use for invalid (e.g. misspelled) variables.

It defaults to the empty string.

See [How invalid variables are handled](#) for details.

- `file_charset` is the charset used to read template files on disk.

It defaults to `'utf-8'`.

- `'libraries'`: A dictionary of labels and dotted Python paths of template tag modules to register with the template engine. This is used to add new libraries or provide alternate labels for existing ones. For example:

```
Engine(
    libraries={
        'myapp_tags': 'path.to.myapp.tags',
        'admin.urls': 'django.contrib.admin.templatetags.admin_urls',
    },
)
```

Libraries can be loaded by passing the corresponding dictionary key to the `{% load %}` tag.

- `'builtins'`: A list of dotted Python paths of template tag modules to add to *built-ins*. For example:

```
Engine(
    builtins=['myapp.builtins'],
)
```

Tags and filters from built-in libraries can be used without first calling the `{% load %}` tag.

The `libraries` and `builtins` arguments were added.

**static** `Engine.get_default()`

When a Django project configures one and only one `DjangoTemplates` engine, this method returns the underlying `Engine`. In other circumstances it will raise `ImproperlyConfigured`.

It's required for preserving APIs that rely on a globally available, implicitly configured engine. Any other use is strongly discouraged.

`Engine.from_string(template_code)`

Compiles the given template code and returns a `Template` object.

`Engine.get_template(template_name)`

Loads a template with the given name, compiles it and returns a `Template` object.

`Engine.select_template(self, template_name_list)`

Like `get_template()`, except it takes a list of names and returns the first template that was found.

## Loading a template

The recommended way to create a `Template` is by calling the factory methods of the `Engine`: `get_template()`, `select_template()` and `from_string()`.

In a Django project where the `TEMPLATES` setting defines exactly one `DjangoTemplates` engine, it's possible to instantiate a `Template` directly.

**class** `Template`

This class lives at `django.template.Template`. The constructor takes one argument — the raw template code:

```
from django.template import Template

template = Template("My name is {{ my_name }}.")
```

---

## Behind the scenes

The system only parses your raw template code once – when you create the `Template` object. From then on, it's stored internally as a tree structure for performance.

Even the parsing itself is quite fast. Most of the parsing happens via a single call to a single, short, regular expression.

---

## Rendering a context

Once you have a compiled `Template` object, you can render a context with it. You can reuse the same template to render it several times with different contexts.

**class** `Context` (`dict=None`)

The constructor of `django.template.Context` takes an optional argument — a dictionary mapping variable names to variable values.

For details, see *Playing with Context objects* below.

`Template.render(context)`

Call the `Template` object's `render()` method with a `Context` to “fill” the template:

```
>>> from django.template import Context, Template
>>> template = Template("My name is {{ my_name }}.")

>>> context = Context({"my_name": "Adrian"})
>>> template.render(context)
"My name is Adrian."

>>> context = Context({"my_name": "Dolores"})
>>> template.render(context)
"My name is Dolores."
```

## Variables and lookups

Variable names must consist of any letter (A-Z), any digit (0-9), an underscore (but they must not start with an underscore) or a dot.

Dots have a special meaning in template rendering. A dot in a variable name signifies a **lookup**. Specifically, when the template system encounters a dot in a variable name, it tries the following lookups, in this order:

- Dictionary lookup. Example: `foo["bar"]`
- Attribute lookup. Example: `foo.bar`
- List-index lookup. Example: `foo[bar]`

Note that “bar” in a template expression like `{{ foo.bar }}` will be interpreted as a literal string and not using the value of the variable “bar”, if one exists in the template context.

The template system uses the first lookup type that works. It’s short-circuit logic. Here are a few examples:

```
>>> from django.template import Context, Template
>>> t = Template("My name is {{ person.first_name }}.")
>>> d = {"person": {"first_name": "Joe", "last_name": "Johnson"}}
>>> t.render(Context(d))
"My name is Joe."

>>> class PersonClass: pass
>>> p = PersonClass()
>>> p.first_name = "Ron"
>>> p.last_name = "Nasty"
>>> t.render(Context({"person": p}))
"My name is Ron."

>>> t = Template("The first stooge in the list is {{ stooges.0 }}.")
>>> c = Context({"stooges": ["Larry", "Curly", "Moe"]})
>>> t.render(c)
"The first stooge in the list is Larry."
```

If any part of the variable is callable, the template system will try calling it. Example:

```
>>> class PersonClass2:
...     def name(self):
...         return "Samantha"
>>> t = Template("My name is {{ person.name }}.")
>>> t.render(Context({"person": PersonClass2}))
"My name is Samantha."
```

Callable variables are slightly more complex than variables which only require straight lookups. Here are some things to keep in mind:

- If the variable raises an exception when called, the exception will be propagated, unless the exception has an attribute `silent_variable_failure` whose value is `True`. If the exception *does* have a `silent_variable_failure` attribute whose value is `True`, the variable will render as the value of the engine's `string_if_invalid` configuration option (an empty string, by default). Example:

```
>>> t = Template("My name is {{ person.first_name }}.")
>>> class PersonClass3:
...     def first_name(self):
...         raise AssertionError("foo")
>>> p = PersonClass3()
>>> t.render(Context({"person": p}))
Traceback (most recent call last):
...
AssertionError: foo

>>> class SilentAssertionError(Exception):
...     silent_variable_failure = True
>>> class PersonClass4:
...     def first_name(self):
...         raise SilentAssertionError
>>> p = PersonClass4()
>>> t.render(Context({"person": p}))
"My name is ."
```

Note that `django.core.exceptions.ObjectDoesNotExist`, which is the base class for all Django database API `DoesNotExist` exceptions, has `silent_variable_failure = True`. So if you're using Django templates with Django model objects, any `DoesNotExist` exception will fail silently.

- A variable can only be called if it has no required arguments. Otherwise, the system will return the value of the engine's `string_if_invalid` option.
- Obviously, there can be side effects when calling some variables, and it'd be either foolish or a security hole to allow the template system to access them.

A good example is the `delete()` method on each Django model object. The template system shouldn't be allowed to do something like this:

```
I will now delete this valuable data. {{ data.delete }}
```

To prevent this, set an `alters_data` attribute on the callable variable. The template system won't call a variable if it has `alters_data=True` set, and will instead replace the variable with `string_if_invalid`, unconditionally. The dynamically-generated `delete()` and `save()` methods on Django model objects get `alters_data=True` automatically. Example:

```
def sensitive_function(self):
    self.database_record.delete()
sensitive_function.alters_data = True
```

- Occasionally you may want to turn off this feature for other reasons, and tell the template system to leave a variable uncalled no matter what. To do so, set a `do_not_call_in_templates` attribute on the callable with the value `True`. The template system then will act as if your variable is not callable (allowing you to access attributes of the callable, for example).

## How invalid variables are handled

Generally, if a variable doesn't exist, the template system inserts the value of the engine's `string_if_invalid` configuration option, which is set to `''` (the empty string) by default.

Filters that are applied to an invalid variable will only be applied if `string_if_invalid` is set to `''` (the empty string). If `string_if_invalid` is set to any other value, variable filters will be ignored.

This behavior is slightly different for the `if`, `for` and `regroup` template tags. If an invalid variable is provided to one of these template tags, the variable will be interpreted as `None`. Filters are always applied to invalid variables within these template tags.

If `string_if_invalid` contains a `'%s'`, the format marker will be replaced with the name of the invalid variable.

---

### For debug purposes only!

While `string_if_invalid` can be a useful debugging tool, it is a bad idea to turn it on as a 'development default'.

Many templates, including those in the Admin site, rely upon the silence of the template system when a non-existent variable is encountered. If you assign a value other than `''` to `string_if_invalid`, you will experience rendering problems with these templates and sites.

Generally, `string_if_invalid` should only be enabled in order to debug a specific template problem, then cleared once debugging is complete.

---

## Built-in variables

Every context contains `True`, `False` and `None`. As you would expect, these variables resolve to the corresponding Python objects.

## Limitations with string literals

Django's template language has no way to escape the characters used for its own syntax. For example, the `templatetag` tag is required if you need to output character sequences like `{%` and `%}`.

A similar issue exists if you want to include these sequences in template filter or tag arguments. For example, when parsing a block tag, Django's template parser looks for the first occurrence of `%}` after a `{%`. This prevents the use of `"%}"` as a string literal. For example, a `TemplateSyntaxError` will be raised for the following expressions:

```
{% include "template.html" tvar="Some string literal with %} in it." %}
{% with tvar="Some string literal with %} in it." %}{% endwith %}
```

The same issue can be triggered by using a reserved sequence in filter arguments:

```
{{ some.variable|default:"}} " }}
```

If you need to use strings with these sequences, store them in template variables or use a custom template tag or filter to workaround the limitation.

## Playing with Context objects

Most of the time, you'll instantiate `Context` objects by passing in a fully-populated dictionary to `Context()`. But you can add and delete items from a `Context` object once it's been instantiated, too, using standard dictionary syntax:

```
>>> from django.template import Context
>>> c = Context({"foo": "bar"})
>>> c['foo']
'bar'
>>> del c['foo']
>>> c['foo']
Traceback (most recent call last):
...
KeyError: 'foo'
>>> c['newvariable'] = 'hello'
>>> c['newvariable']
'hello'
```

`Context.get` (*key*, *otherwise=None*)

Returns the value for *key* if *key* is in the context, else returns *otherwise*.

`Context.setdefault` (*key*, *default=None*)

If *key* is in the context, returns its value. Otherwise inserts *key* with a value of *default* and returns *default*.

`Context.pop` ()

`Context.push` ()

#### exception `ContextPopException`

A `Context` object is a stack. That is, you can `push()` and `pop()` it. If you `pop()` too much, it'll raise `django.template.ContextPopException`:

```
>>> c = Context()
>>> c['foo'] = 'first level'
>>> c.push()
{}
>>> c['foo'] = 'second level'
>>> c['foo']
'second level'
>>> c.pop()
{'foo': 'second level'}
>>> c['foo']
'first level'
>>> c['foo'] = 'overwritten'
>>> c['foo']
'overwritten'
>>> c.pop()
Traceback (most recent call last):
...
ContextPopException
```

You can also use `push()` as a context manager to ensure a matching `pop()` is called.

```
>>> c = Context()
>>> c['foo'] = 'first level'
>>> with c.push():
...     c['foo'] = 'second level'
...     c['foo']
'second level'
>>> c['foo']
'first level'
```

All arguments passed to `push()` will be passed to the `dict` constructor used to build the new context level.

```
>>> c = Context()
>>> c['foo'] = 'first level'
>>> with c.push(foo='second level'):
...     c['foo']
'second level'
>>> c['foo']
'first level'
```

`Context.update(other_dict)`

In addition to `push()` and `pop()`, the `Context` object also defines an `update()` method. This works like `push()` but takes a dictionary as an argument and pushes that dictionary onto the stack instead of an empty one.

```
>>> c = Context()
>>> c['foo'] = 'first level'
>>> c.update({'foo': 'updated'})
{'foo': 'updated'}
>>> c['foo']
'updated'
>>> c.pop()
{'foo': 'updated'}
>>> c['foo']
'first level'
```

Like `push()`, you can use `update()` as a context manager to ensure a matching `pop()` is called.

```
>>> c = Context()
>>> c['foo'] = 'first level'
>>> with c.update({'foo': 'second level'}):
...     c['foo']
'second level'
>>> c['foo']
'first level'
```

The ability to use `update()` as a context manager was added.

Using a `Context` as a stack comes in handy in *some custom template tags*.

`Context.flatten()`

Using `flatten()` method you can get whole `Context` stack as one dictionary including builtin variables.

```
>>> c = Context()
>>> c['foo'] = 'first level'
>>> c.update({'bar': 'second level'})
{'bar': 'second level'}
>>> c.flatten()
{'True': True, 'None': None, 'foo': 'first level', 'False': False, 'bar': 'second_
↪level'}
```

A `flatten()` method is also internally used to make `Context` objects comparable.

```
>>> c1 = Context()
>>> c1['foo'] = 'first level'
>>> c1['bar'] = 'second level'
>>> c2 = Context()
>>> c2.update({'bar': 'second level', 'foo': 'first level'})
{'foo': 'first level', 'bar': 'second level'}
```

```
>>> c1 == c2
True
```

Result from `flatten()` can be useful in unit tests to compare `Context` against `dict`:

```
class ContextTest(unittest.TestCase):
    def test_against_dictionary(self):
        c1 = Context()
        c1['update'] = 'value'
        self.assertEqual(c1.flatten(), {
            'True': True,
            'None': None,
            'False': False,
            'update': 'value',
        })
```

## Using RequestContext

```
class RequestContext(request, dict_=None, processors=None)
```

Django comes with a special `Context` class, `django.template.RequestContext`, that acts slightly differently from the normal `django.template.Context`. The first difference is that it takes an `HttpRequest` as its first argument. For example:

```
c = RequestContext(request, {
    'foo': 'bar',
})
```

The second difference is that it automatically populates the context with a few variables, according to the engine's `context_processors` configuration option.

The `context_processors` option is a list of callables – called **context processors** – that take a request object as their argument and return a dictionary of items to be merged into the context. In the default generated settings file, the default template engine contains the following context processors:

```
[
    'django.template.context_processors.debug',
    'django.template.context_processors.request',
    'django.contrib.auth.context_processors.auth',
    'django.contrib.messages.context_processors.messages',
]
```

In addition to these, `RequestContext` always enables `'django.template.context_processors.csrf'`. This is a security related context processor required by the admin and other contrib apps, and, in case of accidental misconfiguration, it is deliberately hardcoded in and cannot be turned off in the `context_processors` option.

Each processor is applied in order. That means, if one processor adds a variable to the context and a second processor adds a variable with the same name, the second will override the first. The default processors are explained below.

---

### When context processors are applied

Context processors are applied on top of context data. This means that a context processor may overwrite variables you've supplied to your `Context` or `RequestContext`, so take care to avoid variable names that overlap with those supplied by your context processors.

If you want context data to take priority over context processors, use the following pattern:

```
from django.template import RequestContext

request_context = RequestContext(request)
request_context.push({"my_name": "Adrian"})
```

Django does this to allow context data to override context processors in APIs such as `render()` and `TemplateResponse`.

Also, you can give `RequestContext` a list of additional processors, using the optional, third positional argument, `processors`. In this example, the `RequestContext` instance gets a `ip_address` variable:

```
from django.http import HttpResponse
from django.template import RequestContext, Template

def ip_address_processor(request):
    return {'ip_address': request.META['REMOTE_ADDR']}

def client_ip_view(request):
    template = Template('{{ title }}: {{ ip_address }}')
    context = RequestContext(request, {
        'title': 'Your IP Address',
    }, [ip_address_processor])
    return HttpResponse(template.render(context))
```

## Built-in template context processors

Here's what each of the built-in processors does:

### `django.contrib.auth.context_processors.auth`

#### `auth()`

If this processor is enabled, every `RequestContext` will contain these variables:

- `user` – An `auth.User` instance representing the currently logged-in user (or an `AnonymousUser` instance, if the client isn't logged in).
- `perms` – An instance of `django.contrib.auth.context_processors.PermWrapper`, representing the permissions that the currently logged-in user has.

### `django.template.context_processors.debug`

#### `debug()`

If this processor is enabled, every `RequestContext` will contain these two variables – but only if your `DEBUG` setting is set to `True` and the request's IP address (`request.META['REMOTE_ADDR']`) is in the `INTERNAL_IPS` setting:

- `debug` – `True`. You can use this in templates to test whether you're in `DEBUG` mode.
- `sql_queries` – A list of `{'sql': ..., 'time': ...}` dictionaries, representing every SQL query that has happened so far during the request and how long it took. The list is in order by database alias and then by query. It's lazily generated on access.

In older versions, only the queries for the default database alias were included.

#### `django.template.context_processors.i18n`

If this processor is enabled, every `RequestContext` will contain these two variables:

- `LANGUAGES` – The value of the `LANGUAGES` setting.
- `LANGUAGE_CODE` – `request.LANGUAGE_CODE`, if it exists. Otherwise, the value of the `LANGUAGE_CODE` setting.

See *Internationalization and localization* for more.

#### `django.template.context_processors.media`

If this processor is enabled, every `RequestContext` will contain a variable `MEDIA_URL`, providing the value of the `MEDIA_URL` setting.

#### `django.template.context_processors.static`

##### `static()`

If this processor is enabled, every `RequestContext` will contain a variable `STATIC_URL`, providing the value of the `STATIC_URL` setting.

#### `django.template.context_processors.csrf`

This processor adds a token that is needed by the `csrf_token` template tag for protection against *Cross Site Request Forgeries*.

#### `django.template.context_processors.request`

If this processor is enabled, every `RequestContext` will contain a variable `request`, which is the current `HttpRequest`.

#### `django.template.context_processors.tz`

##### `tz()`

If this processor is enabled, every `RequestContext` will contain a variable `TIME_ZONE`, providing the name of the currently active time zone.

#### `django.contrib.messages.context_processors.messages`

If this processor is enabled, every `RequestContext` will contain these two variables:

- `messages` – A list of messages (as strings) that have been set via the *messages framework*.
- `DEFAULT_MESSAGE_LEVELS` – A mapping of the message level names to *their numeric value*.

## Writing your own context processors

A context processor has a very simple interface: It's a Python function that takes one argument, an `HttpRequest` object, and returns a dictionary that gets added to the template context. Each context processor *must* return a dictionary.

Custom context processors can live anywhere in your code base. All Django cares about is that your custom context processors are pointed to by the `'context_processors'` option in your `TEMPLATES` setting — or the `context_processors` argument of `Engine` if you're using it directly.

## Loading templates

Generally, you'll store templates in files on your filesystem rather than using the low-level `Template` API yourself. Save templates in a directory specified as a **template directory**.

Django searches for template directories in a number of places, depending on your template loading settings (see “Loader types” below), but the most basic way of specifying template directories is by using the `DIRS` option.

### The `DIRS` option

Tell Django what your template directories are by using the `DIRS` option in the `TEMPLATES` setting in your settings file — or the `dirs` argument of `Engine`. This should be set to a list of strings that contain full paths to your template directories:

```
TEMPLATES = [
    {
        'BACKEND': 'django.template.backends.django.DjangoTemplates',
        'DIRS': [
            '/home/html/templates/lawrence.com',
            '/home/html/templates/default',
        ],
    },
]
```

Your templates can go anywhere you want, as long as the directories and templates are readable by the Web server. They can have any extension you want, such as `.html` or `.txt`, or they can have no extension at all.

Note that these paths should use Unix-style forward slashes, even on Windows.

## Loader types

By default, Django uses a filesystem-based template loader, but Django comes with a few other template loaders, which know how to load templates from other sources.

Some of these other loaders are disabled by default, but you can activate them by adding a `'loaders'` option to your `DjangoTemplates` backend in the `TEMPLATES` setting or passing a `loaders` argument to `Engine`. `loaders` should be a list of strings or tuples, where each represents a template loader class. Here are the template loaders that come with Django:

```
django.template.loaders.filesystem.Loader
```

### **class** `filesystem.Loader`

Loads templates from the filesystem, according to `DIRS`.

This loader is enabled by default. However it won't find any templates until you set `DIRS` to a non-empty list:

```
TEMPLATES = [{
    'BACKEND': 'django.template.backends.django.DjangoTemplates',
    'DIRS': [os.path.join(BASE_DIR, 'templates')],
}]
```

`django.template.loaders.app_directories.Loader`

**class** `app_directories.Loader`

Loads templates from Django apps on the filesystem. For each app in `INSTALLED_APPS`, the loader looks for a `templates` subdirectory. If the directory exists, Django looks for templates in there.

This means you can store templates with your individual apps. This also makes it easy to distribute Django apps with default templates.

For example, for this setting:

```
INSTALLED_APPS = ['myproject.polls', 'myproject.music']
```

...then `get_template('foo.html')` will look for `foo.html` in these directories, in this order:

- `/path/to/myproject/polls/templates/`
- `/path/to/myproject/music/templates/`

... and will use the one it finds first.

The order of `INSTALLED_APPS` is significant! For example, if you want to customize the Django admin, you might choose to override the standard `admin/base_site.html` template, from `django.contrib.admin`, with your own `admin/base_site.html` in `myproject.polls`. You must then make sure that your `myproject.polls` comes *before* `django.contrib.admin` in `INSTALLED_APPS`, otherwise `django.contrib.admin`'s will be loaded first and yours will be ignored.

Note that the loader performs an optimization when it first runs: it caches a list of which `INSTALLED_APPS` packages have a `templates` subdirectory.

You can enable this loader simply by setting `APP_DIRS` to `True`:

```
TEMPLATES = [{
    'BACKEND': 'django.template.backends.django.DjangoTemplates',
    'APP_DIRS': True,
}]
```

`django.template.loaders.eggs.Loader`

**class** `eggs.Loader`

Deprecated since version 1.9: Distributing applications as eggs is not recommended.

Just like `app_directories` above, but it loads templates from Python eggs rather than from the filesystem.

This loader is disabled by default.

`django.template.loaders.cached.Loader`

**class** `cached.Loader`

By default, the templating system will read and compile your templates every time they need to be rendered. While the Django templating system is quite fast, the overhead from reading and compiling templates can add up.

The cached template loader is a class-based loader that you configure with a list of other loaders that it should wrap. The wrapped loaders are used to locate unknown templates when they are first encountered. The cached loader then stores the compiled `Template` in memory. The cached `Template` instance is returned for subsequent requests to load the same template.

For example, to enable template caching with the `filesystem` and `app_directories` template loaders you might use the following settings:

```
TEMPLATES = [{
    'BACKEND': 'django.template.backends.django.DjangoTemplates',
    'DIRS': [os.path.join(BASE_DIR, 'templates')],
    'OPTIONS': {
        'loaders': [
            ('django.template.loaders.cached.Loader', [
                'django.template.loaders.filesystem.Loader',
                'django.template.loaders.app_directories.Loader',
            ]),
        ],
    },
},
]
```

**Note:** All of the built-in Django template tags are safe to use with the cached loader, but if you're using custom template tags that come from third party packages, or that you wrote yourself, you should ensure that the Node implementation for each tag is thread-safe. For more information, see [template tag thread safety considerations](#).

This loader is disabled by default.

```
django.template.loaders.locmem.Loader
```

#### class `locmem.Loader`

Loads templates from a Python dictionary. This is useful for testing.

This loader takes a dictionary of templates as its first argument:

```
TEMPLATES = [{
    'BACKEND': 'django.template.backends.django.DjangoTemplates',
    'OPTIONS': {
        'loaders': [
            ('django.template.loaders.locmem.Loader', {
                'index.html': 'content here',
            }),
        ],
    },
},
]
```

This loader is disabled by default.

Django uses the template loaders in order according to the `'loaders'` option. It uses each loader until a loader finds a match.

## Custom loaders

It's possible to load templates from additional sources using custom template loaders. Custom Loader classes should inherit from `django.template.loaders.base.Loader` and define the `get_contents()` and `get_template_sources()` methods.

In previous versions of Django, custom loaders defined a single method: `load_template_source()`.

## Loader methods

### class `Loader`

Loads templates from a given source, such as the filesystem or a database.

#### `get_template_sources(template_name)`

A method that takes a `template_name` and yields `Origin` instances for each possible source.

For example, the filesystem loader may receive `'index.html'` as a `template_name` argument. This method would yield origins for the full path of `index.html` as it appears in each template directory the loader looks at.

The method doesn't need to verify that the template exists at a given path, but it should ensure the path is valid. For instance, the filesystem loader makes sure the path lies under a valid template directory.

#### `get_contents(origin)`

Returns the contents for a template given a `Origin` instance.

This is where a filesystem loader would read contents from the filesystem, or a database loader would read from the database. If a matching template doesn't exist, this should raise a `TemplateDoesNotExist` error.

#### `get_template(template_name, skip=None)`

Returns a `Template` object for a given `template_name` by looping through results from `get_template_sources()` and calling `get_contents()`. This returns the first matching template. If no template is found, `TemplateDoesNotExist` is raised.

The optional `skip` argument is a list of origins to ignore when extending templates. This allow templates to extend other templates of the same name. It also used to avoid recursion errors.

In general, it is enough to define `get_template_sources()` and `get_contents()` for custom template loaders. `get_template()` will usually not need to be overridden.

#### `load_template_source(template_name, template_dirs=None)`

Returns a tuple of (`template_string`, `template_origin`), where `template_string` is a string containing the template contents, and `template_origin` is a string identifying the template source. A filesystem-based loader may return the full path to the file as the `template_origin`, for example.

`template_dirs` is an optional argument used to control which directories the loader will search.

This method is called automatically by `load_template()` and should be overridden when writing custom template loaders.

Deprecated since version 1.9: Custom loaders should use `get_template()` and `get_contents()` instead.

#### `load_template(template_name, template_dirs=None)`

Returns a tuple of (`template`, `template_origin`), where `template` is a `Template` object and `template_origin` is a string identifying the template source. A filesystem-based loader may return the full path to the file as the `template_origin`, for example.

Deprecated since version 1.9: Custom loaders should use `get_template()` and `get_contents()` instead.

---

## Building your own

For examples, read the source code for Django's built-in loaders.

---

## Template origin

Templates have an `origin` containing attributes depending on the source they are loaded from.

Django used to create an origin based on `django.template.loader.LoaderOrigin` or `django.template.base.StringOrigin`. These have been replaced by `django.template.base.Origin`.

### class `Origin`

#### `name`

The path to the template as returned by the template loader. For loaders that read from the file system, this is the full path to the template.

If the template is instantiated directly rather than through a template loader, this is a string value of `<unknown_source>`.

#### `template_name`

The relative path to the template as passed into the template loader.

If the template is instantiated directly rather than through a template loader, this is `None`.

## 6.20.4 Upgrading templates to Django 1.8

Django's template system was overhauled in Django 1.8 when it gained support for multiple template engines. This document complements the [release notes](#) with detailed upgrade instructions on some topics.

### The `TEMPLATES` settings

A new setting was introduced in Django 1.8: `TEMPLATES`. All existing template-related settings were deprecated.

During the deprecation period, Django will create a backwards-compatible `TEMPLATES` based on the `TEMPLATE_*` settings if you don't define it yourself.

Here's how to define `TEMPLATES` in your settings module.

If you're using the default value of `TEMPLATE_LOADERS`, that is, if it isn't defined in your settings file or if it's set to:

```
['django.template.loaders.filesystem.Loader',
 'django.template.loaders.app_directories.Loader']
```

then you should define `TEMPLATES` as follows:

```
TEMPLATES = [
    {
        'BACKEND': 'django.template.backends.django.DjangoTemplates',
        'DIRS': [
            # insert your TEMPLATE_DIRS here
        ],
        'APP_DIRS': True,
        'OPTIONS': {
            'context_processors': [
                # Insert your TEMPLATE_CONTEXT_PROCESSORS here or use this
                # list if you haven't customized them:
                'django.contrib.auth.context_processors.auth',
                'django.template.context_processors.debug',
                'django.template.context_processors.i18n',
```

```
        'django.template.context_processors.media',
        'django.template.context_processors.static',
        'django.template.context_processors.tz',
        'django.contrib.messages.context_processors.messages',
    ],
},
],
```

If you aren't using the default value of `TEMPLATE_LOADERS`, then you should define `TEMPLATES` as follows:

```
TEMPLATES = [
    {
        'BACKEND': 'django.template.backends.django.DjangoTemplates',
        'DIRS': [
            # insert your TEMPLATE_DIRS here
        ],
        'OPTIONS': {
            'context_processors': [
                # Insert your TEMPLATE_CONTEXT_PROCESSORS here or use this
                # list if you haven't customized them:
                'django.contrib.auth.context_processors.auth',
                'django.template.context_processors.debug',
                'django.template.context_processors.i18n',
                'django.template.context_processors.media',
                'django.template.context_processors.static',
                'django.template.context_processors.tz',
                'django.contrib.messages.context_processors.messages',
            ],
            'loaders': [
                # insert your TEMPLATE_LOADERS here
            ]
        },
    },
]
```

Furthermore you should replace `django.core.context_processors` with `django.template.context_processors` in the names of context processors.

If your settings module defines `ALLOWED_INCLUDE_ROOTS` or `TEMPLATE_STRING_IF_INVALID`, include their values under the `'allowed_include_roots'` and `'string_if_invalid'` keys in the `'OPTIONS'` dictionary.

If it sets `TEMPLATE_DEBUG` to a value that differs from `DEBUG`, include that value under the `'debug'` key in `'OPTIONS'`.

Once you have defined `TEMPLATES`, you can safely remove `ALLOWED_INCLUDE_ROOTS`, `TEMPLATE_CONTEXT_PROCESSORS`, `TEMPLATE_DEBUG`, `TEMPLATE_DIRS`, `TEMPLATE_LOADERS`, and `TEMPLATE_STRING_IF_INVALID`.

If you are overriding some of these settings in tests, you should override the entire `TEMPLATES` setting instead.

## `django.template.loader`

### `get_template()` and `select_template()`

In Django 1.8 `get_template()` and `select_template()` return a backend-dependent `Template` instead of a `django.template.Template`.

For example, if `get_template()` loads a template with a `DjangoTemplates` backend, then it returns a `django.template.backends.django.Template`.

Template objects must provide a `render()` method whose signature differs slightly from the Django template language's `render()`.

Instead of:

```
from django.template import Context
from django.template.loader import get_template

template = get_template('hello.html')
html = template.render(Context({'name': 'world'}))
```

You should write:

```
from django.template.loader import get_template

template = get_template('hello.html')
html = template.render({'name': 'world'})
```

And instead of:

```
from django.template import RequestContext
from django.template.loader import get_template

template = get_template('hello.html')
html = template.render(RequestContext(request, {'name': 'world'}))
```

You should write:

```
from django.template.loader import get_template

template = get_template('hello.html')
html = template.render({'name': 'world'}, request)
```

Passing a `Context` or a `RequestContext` is still possible when the template is loaded by a `DjangoTemplates` backend but it's deprecated and won't be supported in Django 1.10.

If you're loading a template while you're rendering another template with the Django template language and you have access to the current context, for instance in the `render()` method of a template tag, you can use the current `Engine` directly. Instead of:

```
from django.template.loader import get_template
template = get_template('included.html')
```

You can write:

```
template = context.template.engine.get_template('included.html')
```

This will load the template with the current engine without triggering the multiple template engines machinery, which is usually the desired behavior. Unlike previous solutions, this returns a `django.template.Template`, like `get_template()` used in Django 1.7 and earlier, avoiding all backwards-compatibility problems.

### `get_template_from_string()`

Private API `get_template_from_string(template_code)` was removed in Django 1.8 because it had no way to choose an engine to compile the template.

Three alternatives are available.

If you control the project's setting, you can use one of the configured engines:

```
from django.template import engines

template = engines['django'].from_string(template_code)
```

This returns a backend-dependent `Template` object.

For trivial templates that don't need context processors nor anything else, you can create a bare-bones engine and use its `from_string()` method:

```
from django.template import Engine

template = Engine().from_string(template_code)
```

This returns a `django.template.Template` because `Engine` is part of the Django template language's APIs. The multiple template engines machinery isn't involved here.

Finally, if you have access to the current context, you can use the same trick as above:

```
template = context.template.engine.from_string(template_code)
```

### `Template()`

To a lesser extent, instantiating a template with `Template(template_code)` suffers from the same issue as `get_template_from_string()`.

It still works when the `TEMPLATES` setting defines exactly one `DjangoTemplates` backend, but pluggable applications can't control this requirement.

The last two solutions described in the previous section are recommended in that case.

#### See also:

For information on writing your own custom tags and filters, see [Custom template tags and filters](#).

## 6.21 TemplateResponse and SimpleTemplateResponse

Standard `HttpResponse` objects are static structures. They are provided with a block of pre-rendered content at time of construction, and while that content can be modified, it isn't in a form that makes it easy to perform modifications.

However, it can sometimes be beneficial to allow decorators or middleware to modify a response *after* it has been constructed by the view. For example, you may want to change the template that is used, or put additional data into the context.

TemplateResponse provides a way to do just that. Unlike basic *HttpResponse* objects, TemplateResponse objects retain the details of the template and context that was provided by the view to compute the response. The final output of the response is not computed until it is needed, later in the response process.

### 6.21.1 SimpleTemplateResponse objects

**class SimpleTemplateResponse**

#### Attributes

`SimpleTemplateResponse.template_name`

The name of the template to be rendered. Accepts a backend-dependent template object (such as those returned by `get_template()`), the name of a template, or a list of template names.

Example: `['foo.html', 'path/to/bar.html']`

`SimpleTemplateResponse.context_data`

The context data to be used when rendering the template. It must be a `dict`.

Example: `{'foo': 123}`

`SimpleTemplateResponse.rendered_content`

The current rendered value of the response content, using the current template and context data.

`SimpleTemplateResponse.is_rendered`

A boolean indicating whether the response content has been rendered.

#### Methods

`SimpleTemplateResponse.__init__(template, context=None, content_type=None, status=None, charset=None, using=None)`

Instantiates a *SimpleTemplateResponse* object with the given template, context, content type, HTTP status, and charset.

**template** A backend-dependent template object (such as those returned by `get_template()`), the name of a template, or a list of template names.

**context** A `dict` of values to add to the template context. By default, this is an empty dictionary.

**content\_type** The value included in the HTTP Content-Type header, including the MIME type specification and the character set encoding. If `content_type` is specified, then its value is used. Otherwise, `DEFAULT_CONTENT_TYPE` is used.

**status** The HTTP status code for the response.

**charset** The charset in which the response will be encoded. If not given it will be extracted from `content_type`, and if that is unsuccessful, the `DEFAULT_CHARSET` setting will be used.

**using** The *NAME* of a template engine to use for loading the template.

`SimpleTemplateResponse.resolve_context(context)`

Preprocesses context data that will be used for rendering a template. Accepts a `dict` of context data. By default, returns the same `dict`.

Override this method in order to customize the context.

`SimpleTemplateResponse.resolve_template(template)`

Resolves the template instance to use for rendering. Accepts a backend-dependent template object (such as those returned by `get_template()`), the name of a template, or a list of template names.

Returns the backend-dependent template object instance to be rendered.

Override this method in order to customize template loading.

`SimpleTemplateResponse.add_post_render_callback()`

Add a callback that will be invoked after rendering has taken place. This hook can be used to defer certain processing operations (such as caching) until after rendering has occurred.

If the `SimpleTemplateResponse` has already been rendered, the callback will be invoked immediately.

When called, callbacks will be passed a single argument – the rendered `SimpleTemplateResponse` instance.

If the callback returns a value that is not `None`, this will be used as the response instead of the original response object (and will be passed to the next post rendering callback etc.)

`SimpleTemplateResponse.render()`

Sets `response.content` to the result obtained by `SimpleTemplateResponse.rendered_content`, runs all post-rendering callbacks, and returns the resulting response object.

`render()` will only have an effect the first time it is called. On subsequent calls, it will return the result obtained from the first call.

## 6.21.2 TemplateResponse objects

**class** `TemplateResponse`

`TemplateResponse` is a subclass of `SimpleTemplateResponse` that knows about the current `HttpRequest`.

### Methods

`TemplateResponse.__init__(request, template, context=None, content_type=None, status=None, charset=None, using=None)`

Instantiates a `TemplateResponse` object with the given request, template, context, content type, HTTP status, and charset.

**request** An `HttpRequest` instance.

**template** A backend-dependent template object (such as those returned by `get_template()`), the name of a template, or a list of template names.

**context** A `dict` of values to add to the template context. By default, this is an empty dictionary.

**content\_type** The value included in the HTTP Content-Type header, including the MIME type specification and the character set encoding. If `content_type` is specified, then its value is used. Otherwise, `DEFAULT_CONTENT_TYPE` is used.

**status** The HTTP status code for the response.

**charset** The charset in which the response will be encoded. If not given it will be extracted from `content_type`, and if that is unsuccessful, the `DEFAULT_CHARSET` setting will be used.

**using** The `NAME` of a template engine to use for loading the template.

## 6.21.3 The rendering process

Before a `TemplateResponse` instance can be returned to the client, it must be rendered. The rendering process takes the intermediate representation of template and context, and turns it into the final byte stream that can be served to the client.

There are three circumstances under which a `TemplateResponse` will be rendered:

- When the `TemplateResponse` instance is explicitly rendered, using the `SimpleTemplateResponse.render()` method.
- When the content of the response is explicitly set by assigning `response.content`.
- After passing through template response middleware, but before passing through response middleware.

A `TemplateResponse` can only be rendered once. The first call to `SimpleTemplateResponse.render()` sets the content of the response; subsequent rendering calls do not change the response content.

However, when `response.content` is explicitly assigned, the change is always applied. If you want to force the content to be re-rendered, you can re-evaluate the rendered content, and assign the content of the response manually:

```
# Set up a rendered TemplateResponse
>>> from django.template.response import TemplateResponse
>>> t = TemplateResponse(request, 'original.html', {})
>>> t.render()
>>> print(t.content)
Original content

# Re-rendering doesn't change content
>>> t.template_name = 'new.html'
>>> t.render()
>>> print(t.content)
Original content

# Assigning content does change, no render() call required
>>> t.content = t.rendered_content
>>> print(t.content)
New content
```

## Post-render callbacks

Some operations – such as caching – cannot be performed on an unrendered template. They must be performed on a fully complete and rendered response.

If you're using middleware, the solution is easy. Middleware provides multiple opportunities to process a response on exit from a view. If you put behavior in the response middleware, it's guaranteed to execute after template rendering has taken place.

However, if you're using a decorator, the same opportunities do not exist. Any behavior defined in a decorator is handled immediately.

To compensate for this (and any other analogous use cases), `TemplateResponse` allows you to register callbacks that will be invoked when rendering has completed. Using this callback, you can defer critical processing until a point where you can guarantee that rendered content will be available.

To define a post-render callback, just define a function that takes a single argument – response – and register that function with the template response:

```
from django.template.response import TemplateResponse

def my_render_callback(response):
    # Do content-sensitive processing
    do_post_processing()

def my_view(request):
```

```
# Create a response
response = TemplateResponse(request, 'mytemplate.html', {})
# Register the callback
response.add_post_render_callback(my_render_callback)
# Return the response
return response
```

`my_render_callback()` will be invoked after the `mytemplate.html` has been rendered, and will be provided the fully rendered `TemplateResponse` instance as an argument.

If the template has already been rendered, the callback will be invoked immediately.

## 6.21.4 Using `TemplateResponse` and `SimpleTemplateResponse`

A `TemplateResponse` object can be used anywhere that a normal `django.http.HttpResponse` can be used. It can also be used as an alternative to calling `render()`.

For example, the following simple view returns a `TemplateResponse` with a simple template and a context containing a queryset:

```
from django.template.response import TemplateResponse

def blog_index(request):
    return TemplateResponse(request, 'entry_list.html', {'entries': Entry.objects.
↪all()})
```

## 6.22 Unicode data

Django natively supports Unicode data everywhere. Providing your database can somehow store the data, you can safely pass around Unicode strings to templates, models and the database.

This document tells you what you need to know if you're writing applications that use data or templates that are encoded in something other than ASCII.

### 6.22.1 Creating the database

Make sure your database is configured to be able to store arbitrary string data. Normally, this means giving it an encoding of UTF-8 or UTF-16. If you use a more restrictive encoding – for example, `latin1 (iso8859-1)` – you won't be able to store certain characters in the database, and information will be lost.

- MySQL users, refer to the [MySQL manual](#) for details on how to set or alter the database character set encoding.
- PostgreSQL users, refer to the [PostgreSQL manual](#) (section 22.3.2 in PostgreSQL 9) for details on creating databases with the correct encoding.
- Oracle users, refer to the [Oracle manual](#) for details on how to set (section 2) or alter (section 11) the database character set encoding.
- SQLite users, there is nothing you need to do. SQLite always uses UTF-8 for internal encoding.

All of Django's database backends automatically convert Unicode strings into the appropriate encoding for talking to the database. They also automatically convert strings retrieved from the database into Python Unicode strings. You don't even need to tell Django what encoding your database uses: that is handled transparently.

For more, see the section "The database API" below.

## 6.22.2 General string handling

Whenever you use strings with Django – e.g., in database lookups, template rendering or anywhere else – you have two choices for encoding those strings. You can use Unicode strings, or you can use normal strings (sometimes called “bytestrings”) that are encoded using UTF-8.

In Python 3, the logic is reversed, that is normal strings are Unicode, and when you want to specifically create a bytestring, you have to prefix the string with a ‘b’. As we are doing in Django code from version 1.5, we recommend that you import `unicode_literals` from the `__future__` library in your code. Then, when you specifically want to create a bytestring literal, prefix the string with ‘b’.

Python 2 legacy:

```
my_string = "This is a bytestring"
my_unicode = u"This is an Unicode string"
```

Python 2 with unicode literals or Python 3:

```
from __future__ import unicode_literals

my_string = b"This is a bytestring"
my_unicode = "This is an Unicode string"
```

See also *Python 3 compatibility*.

**Warning:** A bytestring does not carry any information with it about its encoding. For that reason, we have to make an assumption, and Django assumes that all bytestrings are in UTF-8.

If you pass a string to Django that has been encoded in some other format, things will go wrong in interesting ways. Usually, Django will raise a `UnicodeDecodeError` at some point.

If your code only uses ASCII data, it’s safe to use your normal strings, passing them around at will, because ASCII is a subset of UTF-8.

Don’t be fooled into thinking that if your `DEFAULT_CHARSET` setting is set to something other than `'utf-8'` you can use that other encoding in your bytestrings! `DEFAULT_CHARSET` only applies to the strings generated as the result of template rendering (and email). Django will always assume UTF-8 encoding for internal bytestrings. The reason for this is that the `DEFAULT_CHARSET` setting is not actually under your control (if you are the application developer). It’s under the control of the person installing and using your application – and if that person chooses a different setting, your code must still continue to work. Ergo, it cannot rely on that setting.

In most cases when Django is dealing with strings, it will convert them to Unicode strings before doing anything else. So, as a general rule, if you pass in a bytestring, be prepared to receive a Unicode string back in the result.

### Translated strings

Aside from Unicode strings and bytestrings, there’s a third type of string-like object you may encounter when using Django. The framework’s internationalization features introduce the concept of a “lazy translation” – a string that has been marked as translated but whose actual translation result isn’t determined until the object is used in a string. This feature is useful in cases where the translation locale is unknown until the string is used, even though the string might have originally been created when the code was first imported.

Normally, you won’t have to worry about lazy translations. Just be aware that if you examine an object and it claims to be a `django.utils.functional.__proxy__` object, it is a lazy translation. Calling `unicode()` with the lazy translation as the argument will generate a Unicode string in the current locale.

For more details about lazy translation objects, refer to the *internationalization* documentation.

## Useful utility functions

Because some string operations come up again and again, Django ships with a few useful functions that should make working with Unicode and bytestring objects a bit easier.

## Conversion functions

The `django.utils.encoding` module contains a few functions that are handy for converting back and forth between Unicode and bytestrings.

- `smart_text(s, encoding='utf-8', strings_only=False, errors='strict')` converts its input to a Unicode string. The `encoding` parameter specifies the input encoding. (For example, Django uses this internally when processing form input data, which might not be UTF-8 encoded.) The `strings_only` parameter, if set to `True`, will result in Python numbers, booleans and `None` not being converted to a string (they keep their original types). The `errors` parameter takes any of the values that are accepted by Python's `unicode()` function for its error handling.

If you pass `smart_text()` an object that has a `__unicode__` method, it will use that method to do the conversion.

- `force_text(s, encoding='utf-8', strings_only=False, errors='strict')` is identical to `smart_text()` in almost all cases. The difference is when the first argument is a *lazy translation* instance. While `smart_text()` preserves lazy translations, `force_text()` forces those objects to a Unicode string (causing the translation to occur). Normally, you'll want to use `smart_text()`. However, `force_text()` is useful in template tags and filters that absolutely *must* have a string to work with, not just something that can be converted to a string.
- `smart_bytes(s, encoding='utf-8', strings_only=False, errors='strict')` is essentially the opposite of `smart_text()`. It forces the first argument to a bytestring. The `strings_only` parameter has the same behavior as for `smart_text()` and `force_text()`. This is slightly different semantics from Python's builtin `str()` function, but the difference is needed in a few places within Django's internals.

Normally, you'll only need to use `smart_text()`. Call it as early as possible on any input data that might be either Unicode or a bytestring, and from then on, you can treat the result as always being Unicode.

## URI and IRI handling

Web frameworks have to deal with URLs (which are a type of **IRI**). One requirement of URLs is that they are encoded using only ASCII characters. However, in an international environment, you might need to construct a URL from an **IRI** – very loosely speaking, a **URI** that can contain Unicode characters. Quoting and converting an IRI to URI can be a little tricky, so Django provides some assistance.

- The function `django.utils.encoding.iri_to_uri()` implements the conversion from IRI to URI as required by the specification (**RFC 3987#section-3.1**).
- The functions `django.utils.http.urlquote()` and `django.utils.http.urlquote_plus()` are versions of Python's standard `urllib.quote()` and `urllib.quote_plus()` that work with non-ASCII characters. (The data is converted to UTF-8 prior to encoding.)

These two groups of functions have slightly different purposes, and it's important to keep them straight. Normally, you would use `urlquote()` on the individual portions of the IRI or URI path so that any reserved characters such

as `&` or `%` are correctly encoded. Then, you apply `iri_to_uri()` to the full IRI and it converts any non-ASCII characters to the correct encoded values.

**Note:** Technically, it isn't correct to say that `iri_to_uri()` implements the full algorithm in the IRI specification. It doesn't (yet) perform the international domain name encoding portion of the algorithm.

The `iri_to_uri()` function will not change ASCII characters that are otherwise permitted in a URL. So, for example, the character `%` is not further encoded when passed to `iri_to_uri()`. This means you can pass a full URL to this function and it will not mess up the query string or anything like that.

An example might clarify things here:

```
>>> urlquote('Paris & Orléans')
'Paris%20%26%20Orl%C3%A9ans'
>>> iri_to_uri('/favorites/François/%s' % urlquote('Paris & Orléans'))
'/favorites/Fran%C3%A7ois/Paris%20%26%20Orl%C3%A9ans'
```

If you look carefully, you can see that the portion that was generated by `urlquote()` in the second example was not double-quoted when passed to `iri_to_uri()`. This is a very important and useful feature. It means that you can construct your IRI without worrying about whether it contains non-ASCII characters and then, right at the end, call `iri_to_uri()` on the result.

Similarly, Django provides `django.utils.encoding.uri_to_iri()` which implements the conversion from URI to IRI as per [RFC 3987#section-3.2](#). It decodes all percent-encodings except those that don't represent a valid UTF-8 sequence.

An example to demonstrate:

```
>>> uri_to_iri('/%E2%99%A5%E2%99%A5/?utf8=%E2%9C%93')
'/[unicode-heart][unicode-heart]?utf8=✓'
>>> uri_to_iri('%A9helloworld')
'%A9helloworld'
```

In the first example, the UTF-8 characters and reserved characters are unquoted. In the second, the percent-encoding remains unchanged because it lies outside the valid UTF-8 range.

Both `iri_to_uri()` and `uri_to_iri()` functions are idempotent, which means the following is always true:

```
iri_to_uri(iri_to_uri(some_string)) == iri_to_uri(some_string)
uri_to_iri(uri_to_iri(some_string)) == uri_to_iri(some_string)
```

So you can safely call it multiple times on the same URI/IRI without risking double-quoting problems.

### 6.22.3 Models

Because all strings are returned from the database as Unicode strings, model fields that are character based (`CharField`, `TextField`, `URLField`, etc.) will contain Unicode values when Django retrieves data from the database. This is *always* the case, even if the data could fit into an ASCII bytestring.

You can pass in bytestrings when creating a model or populating a field, and Django will convert it to Unicode when it needs to.

#### Choosing between `__str__()` and `__unicode__()`

**Note:** If you are on Python 3, you can skip this section because you'll always create `__str__()` rather than `__unicode__()`. If you'd like compatibility with Python 2, you can decorate your model class with `python_2_unicode_compatible()`.

---

One consequence of using Unicode by default is that you have to take some care when printing data from the model.

In particular, rather than giving your model a `__str__()` method, we recommended you implement a `__unicode__()` method. In the `__unicode__()` method, you can quite safely return the values of all your fields without having to worry about whether they fit into a bytestring or not. (The way Python works, the result of `__str__()` is *always* a bytestring, even if you accidentally try to return a Unicode object).

You can still create a `__str__()` method on your models if you want, of course, but you shouldn't need to do this unless you have a good reason. Django's `Model` base class automatically provides a `__str__()` implementation that calls `__unicode__()` and encodes the result into UTF-8. This means you'll normally only need to implement a `__unicode__()` method and let Django handle the coercion to a bytestring when required.

### Taking care in `get_absolute_url()`

URLs can only contain ASCII characters. If you're constructing a URL from pieces of data that might be non-ASCII, be careful to encode the results in a way that is suitable for a URL. The `reverse()` function handles this for you automatically.

If you're constructing a URL manually (i.e., *not* using the `reverse()` function), you'll need to take care of the encoding yourself. In this case, use the `iri_to_uri()` and `urlquote()` functions that were documented *above*. For example:

```
from django.utils.encoding import iri_to_uri
from django.utils.http import urlquote

def get_absolute_url(self):
    url = '/person/%s/?x=0&y=0' % urlquote(self.location)
    return iri_to_uri(url)
```

This function returns a correctly encoded URL even if `self.location` is something like “Jack visited Paris & Orléans”. (In fact, the `iri_to_uri()` call isn't strictly necessary in the above example, because all the non-ASCII characters would have been removed in quoting in the first line.)

## 6.22.4 The database API

You can pass either Unicode strings or UTF-8 bytestrings as arguments to `filter()` methods and the like in the database API. The following two queriesets are identical:

```
from __future__ import unicode_literals

qs = People.objects.filter(name__contains='Å')
qs = People.objects.filter(name__contains=b'\xc3\x85') # UTF-8 encoding of Å
```

## 6.22.5 Templates

You can use either Unicode or bytestrings when creating templates manually:

```

from __future__ import unicode_literals
from django.template import Template
t1 = Template(b'This is a bytestring template.')
t2 = Template('This is a Unicode template.')

```

But the common case is to read templates from the filesystem, and this creates a slight complication: not all filesystems store their data encoded as UTF-8. If your template files are not stored with a UTF-8 encoding, set the `FILE_CHARSET` setting to the encoding of the files on disk. When Django reads in a template file, it will convert the data from this encoding to Unicode. (`FILE_CHARSET` is set to `'utf-8'` by default.)

The `DEFAULT_CHARSET` setting controls the encoding of rendered templates. This is set to UTF-8 by default.

## Template tags and filters

A couple of tips to remember when writing your own template tags and filters:

- Always return Unicode strings from a template tag's `render()` method and from template filters.
- Use `force_text()` in preference to `smart_text()` in these places. Tag rendering and filter calls occur as the template is being rendered, so there is no advantage to postponing the conversion of lazy translation objects into strings. It's easier to work solely with Unicode strings at that point.

### 6.22.6 Files

If you intend to allow users to upload files, you must ensure that the environment used to run Django is configured to work with non-ASCII file names. If your environment isn't configured correctly, you'll encounter `UnicodeEncodeError` exceptions when saving files with file names that contain non-ASCII characters.

Filesystem support for UTF-8 file names varies and might depend on the environment. Check your current configuration in an interactive Python shell by running:

```

import sys
sys.getfilesystemencoding()

```

This should output "UTF-8".

The `LANG` environment variable is responsible for setting the expected encoding on Unix platforms. Consult the documentation for your operating system and application server for the appropriate syntax and location to set this variable.

In your development environment, you might need to add a setting to your `~/.bashrc` analogous to::

```

export LANG="en_US.UTF-8"

```

### 6.22.7 Email

Django's email framework (in `django.core.mail`) supports Unicode transparently. You can use Unicode data in the message bodies and any headers. However, you're still obligated to respect the requirements of the email specifications, so, for example, email addresses should use only ASCII characters.

The following code example demonstrates that everything except email addresses can be non-ASCII:

```

from __future__ import unicode_literals
from django.core.mail import EmailMessage

```

```
subject = 'My visit to Sør-Trøndelag'
sender = 'Arnbjörg Ráðormsdóttir <arnbjorg@example.com>'
recipients = ['Fred <fred@example.com>']
body = '...'
msg = EmailMessage(subject, body, sender, recipients)
msg.attach("Une pièce jointe.pdf", "%PDF-1.4.%...", mimetype="application/pdf")
msg.send()
```

## 6.22.8 Form submission

HTML form submission is a tricky area. There’s no guarantee that the submission will include encoding information, which means the framework might have to guess at the encoding of submitted data.

Django adopts a “lazy” approach to decoding form data. The data in an `HttpRequest` object is only decoded when you access it. In fact, most of the data is not decoded at all. Only the `HttpRequest.GET` and `HttpRequest.POST` data structures have any decoding applied to them. Those two fields will return their members as Unicode data. All other attributes and methods of `HttpRequest` return data exactly as it was submitted by the client.

By default, the `DEFAULT_CHARSET` setting is used as the assumed encoding for form data. If you need to change this for a particular form, you can set the `encoding` attribute on an `HttpRequest` instance. For example:

```
def some_view(request):
    # We know that the data must be encoded as KOI8-R (for some reason).
    request.encoding = 'koi8-r'
    ...
```

You can even change the encoding after having accessed `request.GET` or `request.POST`, and all subsequent accesses will use the new encoding.

Most developers won’t need to worry about changing form encoding, but this is a useful feature for applications that talk to legacy systems whose encoding you cannot control.

Django does not decode the data of file uploads, because that data is normally treated as collections of bytes, rather than strings. Any automatic decoding there would alter the meaning of the stream of bytes.

## 6.23 `django.urls` utility functions

Deprecated since version 1.10: In older versions, these functions are located in `django.core.urlresolvers`. Importing from the old location will continue to work until Django 2.0.

### 6.23.1 `reverse()`

If you need to use something similar to the `url` template tag in your code, Django provides the following function:

**`reverse`** (*viewname*, *urlconf=None*, *args=None*, *kwargs=None*, *current\_app=None*)

*viewname* can be a *URL pattern name* or the callable view object. For example, given the following url:

```
from news import views

url(r'^archive/$', views.archive, name='news-archive')
```

you can use any of the following to reverse the URL:

```
# using the named URL
reverse('news-archive')

# passing a callable object
# (This is discouraged because you can't reverse namespaced views this way.)
from news import views
reverse(views.archive)
```

If the URL accepts arguments, you may pass them in `args`. For example:

```
from django.urls import reverse

def myview(request):
    return HttpResponseRedirect(reverse('arch-summary', args=[1945]))
```

You can also pass `kwargs` instead of `args`. For example:

```
>>> reverse('admin:app_list', kwargs={'app_label': 'auth'})
'/admin/auth/'
```

`args` and `kwargs` cannot be passed to `reverse()` at the same time.

If no match can be made, `reverse()` raises a `NoReverseMatch` exception.

The `reverse()` function can reverse a large variety of regular expression patterns for URLs, but not every possible one. The main restriction at the moment is that the pattern cannot contain alternative choices using the vertical bar (`"|"`) character. You can quite happily use such patterns for matching against incoming URLs and sending them off to views, but you cannot reverse such patterns.

The `current_app` argument allows you to provide a hint to the resolver indicating the application to which the currently executing view belongs. This `current_app` argument is used as a hint to resolve application namespaces into URLs on specific application instances, according to the [namespaced URL resolution strategy](#).

The `urlconf` argument is the URLconf module containing the URL patterns to use for reversing. By default, the root URLconf for the current thread is used.

**Note:** The string returned by `reverse()` is already *urlquoted*. For example:

```
>>> reverse('cities', args=['Orléans'])
'.../Orl%C3%A9ans/'
```

Applying further encoding (such as `urlquote()` or `urllib.quote()`) to the output of `reverse()` may produce undesirable results.

### 6.23.2 `reverse_lazy()`

A lazily evaluated version of `reverse()`.

**`reverse_lazy`** (*viewname*, *urlconf=None*, *args=None*, *kwargs=None*, *current\_app=None*)

It is useful for when you need to use a URL reversal before your project's URLConf is loaded. Some common cases where this function is necessary are:

- providing a reversed URL as the `url` attribute of a generic class-based view.
- providing a reversed URL to a decorator (such as the `login_url` argument for the `django.contrib.auth.decorators.permission_required()` decorator).

- providing a reversed URL as a default value for a parameter in a function's signature.

### 6.23.3 `resolve()`

The `resolve()` function can be used for resolving URL paths to the corresponding view functions. It has the following signature:

```
resolve (path, urlconf=None)
```

`path` is the URL path you want to resolve. As with `reverse()`, you don't need to worry about the `urlconf` parameter. The function returns a `ResolverMatch` object that allows you to access various metadata about the resolved URL.

If the URL does not resolve, the function raises a `Resolver404` exception (a subclass of `Http404`).

**class `ResolverMatch`**

**func**

The view function that would be used to serve the URL

**args**

The arguments that would be passed to the view function, as parsed from the URL.

**kwargs**

The keyword arguments that would be passed to the view function, as parsed from the URL.

**url\_name**

The name of the URL pattern that matches the URL.

**app\_name**

The application namespace for the URL pattern that matches the URL.

**app\_names**

The list of individual namespace components in the full application namespace for the URL pattern that matches the URL. For example, if the `app_name` is `'foo:bar'`, then `app_names` will be `['foo', 'bar']`.

**namespace**

The instance namespace for the URL pattern that matches the URL.

**namespaces**

The list of individual namespace components in the full instance namespace for the URL pattern that matches the URL. i.e., if the namespace is `foo:bar`, then `namespaces` will be `['foo', 'bar']`.

**view\_name**

The name of the view that matches the URL, including the namespace if there is one.

A `ResolverMatch` object can then be interrogated to provide information about the URL pattern that matches a URL:

```
# Resolve a URL
match = resolve('/some/path/')
# Print the URL pattern that matches the URL
print(match.url_name)
```

A `ResolverMatch` object can also be assigned to a triple:

```
func, args, kwargs = resolve('/some/path/')
```

One possible use of `resolve()` would be to test whether a view would raise a `Http404` error before redirecting to it:

```
from django.urls import resolve
from django.http import HttpResponseRedirect, Http404
from django.utils.six.moves.urllib.parse import urlparse

def myview(request):
    next = request.META.get('HTTP_REFERER', None) or '/'
    response = HttpResponseRedirect(next)

    # modify the request and response as required, e.g. change locale
    # and set corresponding locale cookie

    view, args, kwargs = resolve(urlparse(next)[2])
    kwargs['request'] = request
    try:
        view(*args, **kwargs)
    except Http404:
        return HttpResponseRedirect('/')
    return response
```

### 6.23.4 `get_script_prefix()`

#### `get_script_prefix()`

Normally, you should always use `reverse()` to define URLs within your application. However, if your application constructs part of the URL hierarchy itself, you may occasionally need to generate URLs. In that case, you need to be able to find the base URL of the Django project within its Web server (normally, `reverse()` takes care of this for you). In that case, you can call `get_script_prefix()`, which will return the script prefix portion of the URL for your Django project. If your Django project is at the root of its web server, this is always `"/"`.

## 6.24 `django.conf.urls` utility functions

### 6.24.1 `static()`

`static.static` (*prefix*, *view=django.views.static.serve*, *\*\*kwargs*)

Helper function to return a URL pattern for serving files in debug mode:

```
from django.conf import settings
from django.conf.urls.static import static

urlpatterns = [
    # ... the rest of your URLconf goes here ...
] + static(settings.MEDIA_URL, document_root=settings.MEDIA_ROOT)
```

### 6.24.2 `url()`

`url` (*regex*, *view*, *kwargs=None*, *name=None*)

`urlpatterns` should be a list of `url()` instances. For example:

```
from django.conf.urls import include, url

urlpatterns = [
    url(r'^index/$', index_view, name='main-view'),
    url(r'^weblog/', include('blog.urls')),
    ...
]
```

The `regex` parameter should be a string or `ugettext_lazy()` (see [Translating URL patterns](#)) that contains a regular expression compatible with Python’s `re` module. Strings typically use raw string syntax (`r' '`) so that they can contain sequences like `\d` without the need to escape the backslash with another backslash.

The `view` parameter is a view function or the result of `as_view()` for class-based views. It can also be an `include()`.

The `kwargs` parameter allows you to pass additional arguments to the view function or method. See [Passing extra options to view functions](#) for an example.

See [Naming URL patterns](#) for why the `name` parameter is useful.

### 6.24.3 `include()`

**include** (*module*, *namespace=None*, *app\_name=None*)

**include** (*pattern\_list*)

**include** ((*pattern\_list*, *app\_namespace*), *namespace=None*)

**include** ((*pattern\_list*, *app\_namespace*, *instance\_namespace*))

A function that takes a full Python import path to another URLconf module that should be “included” in this place. Optionally, the [application namespace](#) and [instance namespace](#) where the entries will be included into can also be specified.

Usually, the application namespace should be specified by the included module. If an application namespace is set, the `namespace` argument can be used to set a different instance namespace.

`include()` also accepts as an argument either an iterable that returns URL patterns, a 2-tuple containing such iterable plus the names of the application namespaces, or a 3-tuple containing the iterable and the names of both the application and instance namespace.

#### Parameters

- **module** – URLconf module (or module name)
- **namespace** (*string*) – Instance namespace for the URL entries being included
- **app\_name** (*string*) – Application namespace for the URL entries being included
- **pattern\_list** – Iterable of `django.conf.urls.url()` instances
- **app\_namespace** (*string*) – Application namespace for the URL entries being included
- **instance\_namespace** (*string*) – Instance namespace for the URL entries being included

See [Including other URLconfs](#) and [URL namespaces and included URLconfs](#).

Deprecated since version 1.9: Support for the `app_name` argument is deprecated and will be removed in Django 2.0. Specify the `app_name` as explained in [URL namespaces and included URLconfs](#) instead.

Support for passing a 3-tuple is also deprecated and will be removed in Django 2.0. Pass a 2-tuple containing the pattern list and application namespace, and use the `namespace` argument instead.

Lastly, support for an instance namespace without an application namespace has been deprecated and will be removed in Django 2.0. Specify the application namespace or remove the instance namespace.

### 6.24.4 handler400

#### handler400

A callable, or a string representing the full Python import path to the view that should be called if the HTTP client has sent a request that caused an error condition and a response with a status code of 400.

By default, this is `'django.views.defaults.bad_request'`. If you implement a custom view, be sure it returns an `HttpResponseBadRequest`.

See the documentation about *the 400 (bad request) view* for more information.

### 6.24.5 handler403

#### handler403

A callable, or a string representing the full Python import path to the view that should be called if the user doesn't have the permissions required to access a resource.

By default, this is `'django.views.defaults.permission_denied'`. If you implement a custom view, be sure it returns an `HttpResponseForbidden`.

See the documentation about *the 403 (HTTP Forbidden) view* for more information.

### 6.24.6 handler404

#### handler404

A callable, or a string representing the full Python import path to the view that should be called if none of the URL patterns match.

By default, this is `'django.views.defaults.page_not_found'`. If you implement a custom view, be sure it returns an `HttpResponseNotFound`.

See the documentation about *the 404 (HTTP Not Found) view* for more information.

### 6.24.7 handler500

#### handler500

A callable, or a string representing the full Python import path to the view that should be called in case of server errors. Server errors happen when you have runtime errors in view code.

By default, this is `'django.views.defaults.server_error'`. If you implement a custom view, be sure it returns an `HttpResponseServerError`.

See the documentation about *the 500 (HTTP Internal Server Error) view* for more information.

## 6.25 Django Utils

This document covers all stable modules in `django.utils`. Most of the modules in `django.utils` are designed for internal use and only the following parts can be considered stable and thus backwards compatible as per the *internal release deprecation policy*.

### 6.25.1 `django.utils.cache`

This module contains helper functions for controlling caching. It does so by managing the `Vary` header of responses. It includes functions to patch the header of response objects directly and decorators that change functions to do that header-patching themselves.

For information on the `Vary` header, see [RFC 7231#section-7.1.4](#).

Essentially, the `Vary` HTTP header defines which headers a cache should take into account when building its cache key. Requests with the same path but different header content for headers named in `Vary` need to get different cache keys to prevent delivery of wrong content.

For example, *internationalization* middleware would need to distinguish caches by the `Accept-language` header.

**`patch_cache_control`** (*response*, *\*\*kwargs*)

This function patches the `Cache-Control` header by adding all keyword arguments to it. The transformation is as follows:

- All keyword parameter names are turned to lowercase, and underscores are converted to hyphens.
- If the value of a parameter is `True` (exactly `True`, not just a `true` value), only the parameter name is added to the header.
- All other parameters are added with their value, after applying `str()` to it.

**`get_max_age`** (*response*)

Returns the max-age from the response `Cache-Control` header as an integer (or `None` if it wasn't found or wasn't an integer).

**`patch_response_headers`** (*response*, *cache\_timeout=None*)

Adds some useful headers to the given `HttpResponse` object:

- `ETag`
- `Last-Modified`
- `Expires`
- `Cache-Control`

Each header is only added if it isn't already set.

`cache_timeout` is in seconds. The `CACHE_MIDDLEWARE_SECONDS` setting is used by default.

**`add_never_cache_headers`** (*response*)

Adds a `Cache-Control: max-age=0, no-cache, no-store, must-revalidate` header to a response to indicate that a page should never be cached.

In older versions, `Cache-Control: max-age=0` was sent. This didn't reliably prevent caching in all browsers.

**`patch_vary_headers`** (*response*, *newheaders*)

Adds (or updates) the `Vary` header in the given `HttpResponse` object. `newheaders` is a list of header names that should be in `Vary`. Existing headers in `Vary` aren't removed.

**get\_cache\_key** (*request*, *key\_prefix=None*)

Returns a cache key based on the request path. It can be used in the request phase because it pulls the list of headers to take into account from the global path registry and uses those to build a cache key to check against.

If there is no headerlist stored, the page needs to be rebuilt, so this function returns `None`.

**learn\_cache\_key** (*request*, *response*, *cache\_timeout=None*, *key\_prefix=None*)

Learns what headers to take into account for some request path from the response object. It stores those headers in a global path registry so that later access to that path will know what headers to take into account without building the response object itself. The headers are named in the `Vary` header of the response, but we want to prevent response generation.

The list of headers to use for cache key generation is stored in the same cache as the pages themselves. If the cache ages some data out of the cache, this just means that we have to build the response once to get at the `Vary` header and so at the list of headers to use for the cache key.

## 6.25.2 `django.utils.dateparse`

The functions defined in this module share the following properties:

- They raise `ValueError` if their input is well formatted but isn't a valid date or time.
- They return `None` if it isn't well formatted at all.
- They accept up to picosecond resolution in input, but they truncate it to microseconds, since that's what Python supports.

**parse\_date** (*value*)

Parses a string and returns a `datetime.date`.

**parse\_time** (*value*)

Parses a string and returns a `datetime.time`.

UTC offsets aren't supported; if *value* describes one, the result is `None`.

**parse\_datetime** (*value*)

Parses a string and returns a `datetime.datetime`.

UTC offsets are supported; if *value* describes one, the result's `tzinfo` attribute is a `FixedOffset` instance.

**parse\_duration** (*value*)

Parses a string and returns a `datetime.timedelta`.

Expects data in the format "`DD HH:MM:SS.uuuuuu`" or as specified by ISO 8601 (e.g. `P4DT1H15M20S` which is equivalent to `4 1:15:20`).

## 6.25.3 `django.utils.decorators`

**method\_decorator** (*decorator*, *name=''*)

Converts a function decorator into a method decorator. It can be used to decorate methods or classes; in the latter case, *name* is the name of the method to be decorated and is required.

*decorator* may also be a list or tuple of functions. They are wrapped in reverse order so that the call order is the order in which the functions appear in the list/tuple.

See *decorating class based views* for example usage.

The ability to decorate classes, the *name* parameter, and the ability for *decorator* to accept a list/tuple of decorator functions were added.

**decorator\_from\_middleware** (*middleware\_class*)

Given a middleware class, returns a view decorator. This lets you use middleware functionality on a per-view basis. The middleware is created with no params passed.

It assumes middleware that's compatible with the old style of Django 1.9 and earlier (having methods like `process_request()`, `process_exception()`, and `process_response()`).

**decorator\_from\_middleware\_with\_args** (*middleware\_class*)

Like `decorator_from_middleware`, but returns a function that accepts the arguments to be passed to the `middleware_class`. For example, the `cache_page()` decorator is created from the `CacheMiddleware` like this:

```
cache_page = decorator_from_middleware_with_args(CacheMiddleware)

@cache_page(3600)
def my_view(request):
    pass
```

## 6.25.4 django.utils.encoding

**python\_2\_unicode\_compatible** ()

A decorator that defines `__unicode__` and `__str__` methods under Python 2. Under Python 3 it does nothing.

To support Python 2 and 3 with a single code base, define a `__str__` method returning text and apply this decorator to the class.

**smart\_text** (*s*, *encoding='utf-8'*, *strings\_only=False*, *errors='strict'*)

Returns a text object representing *s* – unicode on Python 2 and `str` on Python 3. Treats bytestrings using the `encoding` codec.

If `strings_only` is `True`, don't convert (some) non-string-like objects.

**smart\_unicode** (*s*, *encoding='utf-8'*, *strings\_only=False*, *errors='strict'*)

Historical name of `smart_text()`. Only available under Python 2.

**is\_protected\_type** (*obj*)

Determine if the object instance is of a protected type.

Objects of protected types are preserved as-is when passed to `force_text(strings_only=True)`.

**force\_text** (*s*, *encoding='utf-8'*, *strings\_only=False*, *errors='strict'*)

Similar to `smart_text`, except that lazy instances are resolved to strings, rather than kept as lazy objects.

If `strings_only` is `True`, don't convert (some) non-string-like objects.

**force\_unicode** (*s*, *encoding='utf-8'*, *strings\_only=False*, *errors='strict'*)

Historical name of `force_text()`. Only available under Python 2.

**smart\_bytes** (*s*, *encoding='utf-8'*, *strings\_only=False*, *errors='strict'*)

Returns a bytestring version of *s*, encoded as specified in `encoding`.

If `strings_only` is `True`, don't convert (some) non-string-like objects.

**force\_bytes** (*s*, *encoding='utf-8'*, *strings\_only=False*, *errors='strict'*)

Similar to `smart_bytes`, except that lazy instances are resolved to bytestrings, rather than kept as lazy objects.

If `strings_only` is `True`, don't convert (some) non-string-like objects.

**smart\_str** (*s*, *encoding='utf-8'*, *strings\_only=False*, *errors='strict'*)

Alias of `smart_bytes()` on Python 2 and `smart_text()` on Python 3. This function returns a `str` or a lazy string.

For instance, this is suitable for writing to `sys.stdout` on Python 2 and 3.

**force\_str** (*s*, *encoding='utf-8'*, *strings\_only=False*, *errors='strict'*)

Alias of `force_bytes()` on Python 2 and `force_text()` on Python 3. This function always returns a `str`.

**iri\_to\_uri** (*iri*)

Convert an Internationalized Resource Identifier (IRI) portion to a URI portion that is suitable for inclusion in a URL.

This is the algorithm from section 3.1 of [RFC 3987#section-3.1](#). However, since we are assuming input is either UTF-8 or unicode already, we can simplify things a little from the full method.

Takes an IRI in UTF-8 bytes and returns ASCII bytes containing the encoded result.

**uri\_to\_iri** (*uri*)

Converts a Uniform Resource Identifier into an Internationalized Resource Identifier.

This is an algorithm from section 3.2 of [RFC 3987#section-3.2](#).

Takes a URI in ASCII bytes and returns a unicode string containing the encoded result.

**filepath\_to\_uri** (*path*)

Convert a file system path to a URI portion that is suitable for inclusion in a URL. The path is assumed to be either UTF-8 or unicode.

This method will encode certain characters that would normally be recognized as special characters for URIs. Note that this method does not encode the `'` character, as it is a valid character within URIs. See `encodeURIComponent()` JavaScript function for more details.

Returns an ASCII string containing the encoded result.

**escape\_uri\_path** (*path*)

Escapes the unsafe characters from the path portion of a Uniform Resource Identifier (URI).

## 6.25.5 django.utils.feedgenerator

Sample usage:

```
>>> from django.utils import feedgenerator
>>> feed = feedgenerator.Rss201rev2Feed(
...     title="Poynter E-Media Tidbits",
...     link="http://www.poynter.org/column.asp?id=31",
...     description="A group Weblog by the sharpest minds in online media/journalism/
↳ publishing.",
...     language="en",
... )
>>> feed.add_item(
...     title="Hello",
...     link="http://www.holovaty.com/test/",
...     description="Testing.",
... )
>>> with open('test.rss', 'w') as fp:
...     feed.write(fp, 'utf-8')
```

For simplifying the selection of a generator use `feedgenerator.DefaultFeed` which is currently `Rss201rev2Feed`

For definitions of the different versions of RSS, see: <https://web.archive.org/web/20110718035220/http://diveintomark.org/archives/2004/02/04/incompatible-rss>

**get\_tag\_uri** (*url, date*)

Creates a TagURI.

See <https://web.archive.org/web/20110514113830/http://diveintomark.org/archives/2004/05/28/howto-atom-id>

## SyndicationFeed

**class SyndicationFeed**

Base class for all syndication feeds. Subclasses should provide `write()`.

**\_\_init\_\_** (*title, link, description, language=None, author\_email=None, author\_name=None, author\_link=None, subtitle=None, categories=None, feed\_url=None, feed\_copyright=None, feed\_guid=None, ttl=None, \*\*kwargs*)

Initialize the feed with the given dictionary of metadata, which applies to the entire feed.

Any extra keyword arguments you pass to `__init__` will be stored in `self.feed`.

All parameters should be Unicode objects, except `categories`, which should be a sequence of Unicode objects.

**add\_item** (*title, link, description, author\_email=None, author\_name=None, author\_link=None, pubdate=None, comments=None, unique\_id=None, enclosure=None, categories=(), item\_copyright=None, ttl=None, updateddate=None, enclosures=None, \*\*kwargs*)

Adds an item to the feed. All args are expected to be Python unicode objects except `pubdate` and `updateddate`, which are `datetime.datetime` objects, `enclosure`, which is an `Enclosure` instance, and `enclosures`, which is a list of `Enclosure` instances.

Deprecated since version 1.9: The `enclosure` keyword argument is deprecated in favor of the new `enclosures` keyword argument which accepts a list of `Enclosure` objects.

**num\_items** ()

**root\_attributes** ()

Return extra attributes to place on the root (i.e. feed/channel) element. Called from `write()`.

**add\_root\_elements** (*handler*)

Add elements in the root (i.e. feed/channel) element. Called from `write()`.

**item\_attributes** (*item*)

Return extra attributes to place on each item (i.e. item/entry) element.

**add\_item\_elements** (*handler, item*)

Add elements on each item (i.e. item/entry) element.

**write** (*outfile, encoding*)

Outputs the feed in the given encoding to `outfile`, which is a file-like object. Subclasses should override this.

**writeString** (*encoding*)

Returns the feed in the given encoding as a string.

**latest\_post\_date** ()

Returns the latest `pubdate` or `updateddate` for all items in the feed. If no items have either of these attributes this returns the current date/time.

## Enclosure

### class Enclosure

Represents an RSS enclosure

## RssFeed

class RssFeed (*SyndicationFeed*)

## Rss201rev2Feed

class Rss201rev2Feed (*RssFeed*)

Spec: <https://cyber.law.harvard.edu/rss/rss.html>

## RssUserland091Feed

class RssUserland091Feed (*RssFeed*)

Spec: <http://backend.userland.com/rss091>

## Atom1Feed

class Atom1Feed (*SyndicationFeed*)

Spec: <https://tools.ietf.org/html/rfc4287>

## 6.25.6 django.utils.functional

class cached\_property (*object, name*)

The `@cached_property` decorator caches the result of a method with a single `self` argument as a property. The cached result will persist as long as the instance does, so if the instance is passed around and the function subsequently invoked, the cached result will be returned.

Consider a typical case, where a view might need to call a model's method to perform some computation, before placing the model instance into the context, where the template might invoke the method once more:

```
# the model
class Person(models.Model):

    def friends(self):
        # expensive computation
        ...
        return friends

# in the view:
if person.friends():
    ...
```

And in the template you would have:

```
{% for friend in person.friends %}
```

Here, `friends()` will be called twice. Since the instance `person` in the view and the template are the same, `@cached_property` can avoid that:

```
from django.utils.functional import cached_property

@cached_property
def friends(self):
    # expensive computation
    ...
    return friends
```

Note that as the method is now a property, in Python code it will need to be invoked appropriately:

```
# in the view:
if person.friends:
    ...
```

The cached value can be treated like an ordinary attribute of the instance:

```
# clear it, requiring re-computation next time it's called
del person.friends # or setattr(person, "friends")

# set a value manually, that will persist on the instance until cleared
person.friends = ["Huckleberry Finn", "Tom Sawyer"]
```

As well as offering potential performance advantages, `@cached_property` can ensure that an attribute's value does not change unexpectedly over the life of an instance. This could occur with a method whose computation is based on `datetime.now()`, or simply if a change were saved to the database by some other process in the brief interval between subsequent invocations of a method on the same instance.

You can use the `name` argument to make cached properties of other methods. For example, if you had an expensive `get_friends()` method and wanted to allow calling it without retrieving the cached value, you could write:

```
friends = cached_property(get_friends, name='friends')
```

While `person.get_friends()` will recompute the friends on each call, the value of the cached property will persist until you delete it as described above:

```
x = person.friends           # calls first time
y = person.get_friends()    # calls again
z = person.friends           # does not call
x is z                       # is True
```

**allow\_lazy** (*func*, \**resultclasses*)

Deprecated since version 1.10.

Works like `keep_lazy()` except that it can't be used as a decorator.

**keep\_lazy** (*func*, \**resultclasses*)

Django offers many utility functions (particularly in `django.utils`) that take a string as their first argument and do something to that string. These functions are used by template filters as well as directly in other code.

If you write your own similar functions and deal with translations, you'll face the problem of what to do when the first argument is a lazy translation object. You don't want to convert it to a string immediately, because you might be using this function outside of a view (and hence the current thread's locale setting will not be correct).

For cases like this, use the `django.utils.functional.keep_lazy()` decorator. It modifies the function so that *if* it's called with a lazy translation as one of its arguments, the function evaluation is delayed until it needs to be converted to a string.

For example:

```

from django.utils import six
from django.utils.functional import keep_lazy, keep_lazy_text

def fancy_utility_function(s, ...):
    # Do some conversion on string 's'
    ...
fancy_utility_function = keep_lazy(six.text_type)(fancy_utility_function)

# Or more succinctly:
@keep_lazy(six.text_type)
def fancy_utility_function(s, ...):
    ...

```

The `keep_lazy()` decorator takes a number of extra arguments (`*args`) specifying the type(s) that the original function can return. A common use case is to have functions that return text. For these, you can just pass the `six.text_type` type to `keep_lazy` (or even simpler, use the `keep_lazy_text()` decorator described in the next section).

Using this decorator means you can write your function and assume that the input is a proper string, then add support for lazy translation objects at the end.

#### **keep\_lazy\_text** (*func*)

A shortcut for `keep_lazy(six.text_type)(func)`.

If you have a function that returns text and you want to be able to take lazy arguments while delaying their evaluation, simply use this decorator:

```

from django.utils import six
from django.utils.functional import keep_lazy, keep_lazy_text

# Our previous example was:
@keep_lazy(six.text_type)
def fancy_utility_function(s, ...):
    ...

# Which can be rewritten as:
@keep_lazy_text
def fancy_utility_function(s, ...):
    ...

```

## 6.25.7 `django.utils.html`

Usually you should build up HTML using Django's templates to make use of its autoescape mechanism, using the utilities in `django.utils.safestring` where appropriate. This module provides some additional low level utilities for escaping HTML.

#### **escape** (*text*)

Returns the given text with ampersands, quotes and angle brackets encoded for use in HTML. The input is first passed through `force_text()` and the output has `mark_safe()` applied.

#### **conditional\_escape** (*text*)

Similar to `escape()`, except that it doesn't operate on pre-escaped strings, so it will not double escape.

#### **format\_html** (*format\_string*, *\*args*, *\*\*kwargs*)

This is similar to `str.format()`, except that it is appropriate for building up HTML fragments. All args and kwargs are passed through `conditional_escape()` before being passed to `str.format()`.

For the case of building up small HTML fragments, this function is to be preferred over string interpolation using `%` or `str.format()` directly, because it applies escaping to all arguments - just like the template system applies escaping by default.

So, instead of writing:

```
mark_safe("%s <b>%s</b> %s" % (
    some_html,
    escape(some_text),
    escape(some_other_text),
))
```

You should instead use:

```
format_html("{} <b>{}</b> {}",
    mark_safe(some_html),
    some_text,
    some_other_text,
)
```

This has the advantage that you don't need to apply `escape()` to each argument and risk a bug and an XSS vulnerability if you forget one.

Note that although this function uses `str.format()` to do the interpolation, some of the formatting options provided by `str.format()` (e.g. number formatting) will not work, since all arguments are passed through `conditional_escape()` which (ultimately) calls `force_text()` on the values.

#### **format\_html\_join**(*sep*, *format\_string*, *args\_generator*)

A wrapper of `format_html()`, for the common case of a group of arguments that need to be formatted using the same format string, and then joined using `sep`. `sep` is also passed through `conditional_escape()`.

`args_generator` should be an iterator that returns the sequence of `args` that will be passed to `format_html()`. For example:

```
format_html_join(
    '\n', "<li>{} {}</li>",
    ((u.first_name, u.last_name) for u in users)
)
```

#### **strip\_tags**(*value*)

Tries to remove anything that looks like an HTML tag from the string, that is anything contained within `<>`.

Absolutely NO guarantee is provided about the resulting string being HTML safe. So NEVER mark safe the result of a `strip_tag` call without escaping it first, for example with `escape()`.

For example:

```
strip_tags(value)
```

If `value` is `"<b>Joel</b> <button>is</button> a <span>slug</span>"` the return value will be `"Joel is a slug"`.

If you are looking for a more robust solution, take a look at the [bleach](#) Python library.

#### **html\_safe**()

The `__html__()` method on a class helps non-Django templates detect classes whose output doesn't require HTML escaping.

This decorator defines the `__html__()` method on the decorated class by wrapping the `__unicode__()` (Python 2) or `__str__()` (Python 3) in `mark_safe()`. Ensure the `__unicode__()` or `__str__()` method does indeed return text that doesn't require HTML escaping.

## 6.25.8 `django.utils.http`

**`urlquote`** (*url*, *safe*='')

A version of Python's `urllib.quote()` function that can operate on unicode strings. The url is first UTF-8 encoded before quoting. The returned string can safely be used as part of an argument to a subsequent `iri_to_uri()` call without double-quoting occurring. Employs lazy execution.

**`urlquote_plus`** (*url*, *safe*='')

A version of Python's `urllib.quote_plus()` function that can operate on unicode strings. The url is first UTF-8 encoded before quoting. The returned string can safely be used as part of an argument to a subsequent `iri_to_uri()` call without double-quoting occurring. Employs lazy execution.

**`urlencode`** (*query*, *doseq*=0)

A version of Python's `urllib.urlencode()` function that can operate on unicode strings. The parameters are first cast to UTF-8 encoded strings and then encoded as per normal.

**`cookie_date`** (*epoch\_seconds*=None)

Formats the time to ensure compatibility with Netscape's cookie standard.

Accepts a floating point number expressed in seconds since the epoch in UTC—such as that outputted by `time.time()`. If set to `None`, defaults to the current time.

Outputs a string in the format `Wdy, DD-Mon-YYYY HH:MM:SS GMT`.

**`http_date`** (*epoch\_seconds*=None)

Formats the time to match the [RFC 1123](#) date format as specified by HTTP [RFC 7231#section-7.1.1.1](#).

Accepts a floating point number expressed in seconds since the epoch in UTC—such as that outputted by `time.time()`. If set to `None`, defaults to the current time.

Outputs a string in the format `Wdy, DD Mon YYYY HH:MM:SS GMT`.

**`base36_to_int`** (*s*)

Converts a base 36 string to an integer. On Python 2 the output is guaranteed to be an `int` and not a `long`.

**`int_to_base36`** (*i*)

Converts a positive integer to a base 36 string. On Python 2 *i* must be smaller than `sys.maxint`.

**`urlsafe_base64_encode`** (*s*)

Encodes a bytestring in base64 for use in URLs, stripping any trailing equal signs.

**`urlsafe_base64_decode`** (*s*)

Decodes a base64 encoded string, adding back any trailing equal signs that might have been stripped.

## 6.25.9 `django.utils.module_loading`

Functions for working with Python modules.

**`import_string`** (*dotted\_path*)

Imports a dotted module path and returns the attribute/class designated by the last name in the path. Raises `ImportError` if the import failed. For example:

```
from django.utils.module_loading import import_string
ValidationError = import_string('django.core.exceptions.ValidationError')
```

is equivalent to:

```
from django.core.exceptions import ValidationError
```

## 6.25.10 `django.utils.safestring`

Functions and classes for working with “safe strings”: strings that can be displayed safely without further escaping in HTML. Marking something as a “safe string” means that the producer of the string has already turned characters that should not be interpreted by the HTML engine (e.g. ‘<’) into the appropriate entities.

### class `SafeBytes`

A `bytes` subclass that has been specifically marked as “safe” (requires no further escaping) for HTML output purposes.

### class `SafeString`

A `str` subclass that has been specifically marked as “safe” (requires no further escaping) for HTML output purposes. This is `SafeBytes` on Python 2 and `SafeText` on Python 3.

### class `SafeText`

A `str` (in Python 3) or `unicode` (in Python 2) subclass that has been specifically marked as “safe” for HTML output purposes.

### class `SafeUnicode`

Historical name of `SafeText`. Only available under Python 2.

### `mark_safe(s)`

Explicitly mark a string as safe for (HTML) output purposes. The returned object can be used everywhere a string or unicode object is appropriate.

Can be called multiple times on a single string.

For building up fragments of HTML, you should normally be using `django.utils.html.format_html()` instead.

String marked safe will become unsafe again if modified. For example:

```
>>> mystr = '<b>Hello World</b>  '
>>> mystr = mark_safe(mystr)
>>> type(mystr)
<class 'django.utils.safestring.SafeBytes'>

>>> mystr = mystr.strip() # removing whitespace
>>> type(mystr)
<type 'str'>
```

### `mark_for_escaping(s)`

Deprecated since version 1.10.

Explicitly mark a string as requiring HTML escaping upon output. Has no effect on `SafeData` subclasses.

Can be called multiple times on a single string (the resulting escaping is only applied once).

## 6.25.11 `django.utils.text`

### `slugify(allow_unicode=False)`

Converts to ASCII if `allow_unicode` is `False` (default). Converts spaces to hyphens. Removes characters that aren’t alphanumeric, underscores, or hyphens. Converts to lowercase. Also strips leading and trailing whitespace.

For example:

```
slugify(value)
```

If value is "Joel is a slug", the output will be "joel-is-a-slug".

You can set the `allow_unicode` parameter to `True`, if you want to allow Unicode characters:

```
slugify(value, allow_unicode=True)
```

If value is " World", the output will be "-world".

The `allow_unicode` parameter was added.

## 6.25.12 django.utils.timezone

### utc

`tzinfo` instance that represents UTC.

### class FixedOffset (offset=None, name=None)

A `tzinfo` subclass modeling a fixed offset from UTC. `offset` is an integer number of minutes east of UTC.

### get\_fixed\_timezone (offset)

Returns a `tzinfo` instance that represents a time zone with a fixed offset from UTC.

`offset` is a `datetime.timedelta` or an integer number of minutes. Use positive values for time zones east of UTC and negative values for west of UTC.

### get\_default\_timezone ()

Returns a `tzinfo` instance that represents the *default time zone*.

### get\_default\_timezone\_name ()

Returns the name of the *default time zone*.

### get\_current\_timezone ()

Returns a `tzinfo` instance that represents the *current time zone*.

### get\_current\_timezone\_name ()

Returns the name of the *current time zone*.

### activate (timezone)

Sets the *current time zone*. The `timezone` argument must be an instance of a `tzinfo` subclass or, if `pytz` is available, a time zone name.

### deactivate ()

Unsets the *current time zone*.

### override (timezone)

This is a Python context manager that sets the *current time zone* on entry with `activate ()`, and restores the previously active time zone on exit. If the `timezone` argument is `None`, the *current time zone* is unset on entry with `deactivate ()` instead.

`override` is also usable as a function decorator.

### localtime (value, timezone=None)

Converts an aware `datetime` to a different time zone, by default the *current time zone*.

This function doesn't work on naive datetimes; use `make_aware ()` instead.

### now ()

Returns a `datetime` that represents the current point in time. Exactly what's returned depends on the value of `USE_TZ`:

- If `USE_TZ` is `False`, this will be a *naive* datetime (i.e. a datetime without an associated timezone) that represents the current time in the system's local timezone.

- If `USE_TZ` is `True`, this will be an *aware* datetime representing the current time in UTC. Note that `now()` will always return times in UTC regardless of the value of `TIME_ZONE`; you can use `localtime()` to convert to a time in the current time zone.

**is\_aware** (*value*)

Returns `True` if *value* is aware, `False` if it is naive. This function assumes that *value* is a `datetime`.

**is\_naive** (*value*)

Returns `True` if *value* is naive, `False` if it is aware. This function assumes that *value* is a `datetime`.

**make\_aware** (*value*, *timezone=None*, *is\_dst=None*)

Returns an aware `datetime` that represents the same point in time as *value* in *timezone*, *value* being a naive `datetime`. If *timezone* is set to `None`, it defaults to the *current time zone*.

When `pytz` is installed, the exception `pytz.AmbiguousTimeError` will be raised if you try to make *value* aware during a DST transition where the same time occurs twice (when reverting from DST). Setting `is_dst` to `True` or `False` will avoid the exception by choosing if the time is pre-transition or post-transition respectively.

When `pytz` is installed, the exception `pytz.NonExistentTimeError` will be raised if you try to make *value* aware during a DST transition such that the time never occurred (when entering into DST). Setting `is_dst` to `True` or `False` will avoid the exception by moving the hour backwards or forwards by 1 respectively. For example, `is_dst=True` would change a non-existent time of 2:30 to 1:30 and `is_dst=False` would change the time to 3:30.

`is_dst` has no effect when `pytz` is not installed.

The `is_dst` argument was added.

**make\_naive** (*value*, *timezone=None*)

Returns a naive `datetime` that represents in *timezone* the same point in time as *value*, *value* being an aware `datetime`. If *timezone* is set to `None`, it defaults to the *current time zone*.

### 6.25.13 `django.utils.translation`

For a complete discussion on the usage of the following see the *translation documentation*.

**gettext** (*message*)

Translates *message* and returns it in a UTF-8 bytestring

**ugettext** (*message*)

Translates *message* and returns it in a unicode string

**pgettext** (*context*, *message*)

Translates *message* given the *context* and returns it in a unicode string.

For more information, see *Contextual markers*.

**gettext\_lazy** (*message*)

**ugettext\_lazy** (*message*)

**pgettext\_lazy** (*context*, *message*)

Same as the non-lazy versions above, but using lazy execution.

See *lazy translations documentation*.

**gettext\_noop** (*message*)

**ugettext\_noop** (*message*)

Marks strings for translation but doesn't translate them now. This can be used to store strings in global variables that should stay in the base language (because they might be used externally) and will be translated later.

**ngettext** (*singular, plural, number*)

Translates `singular` and `plural` and returns the appropriate string based on `number` in a UTF-8 bytestring.

**ungettext** (*singular, plural, number*)

Translates `singular` and `plural` and returns the appropriate string based on `number` in a unicode string.

**npgettext** (*context, singular, plural, number*)

Translates `singular` and `plural` and returns the appropriate string based on `number` and the `context` in a unicode string.

**ngettext\_lazy** (*singular, plural, number*)

**ungettext\_lazy** (*singular, plural, number*)

**npgettext\_lazy** (*context, singular, plural, number*)

Same as the non-lazy versions above, but using lazy execution.

See *lazy translations documentation*.

**string\_concat** (*\*strings*)

Lazy variant of string concatenation, needed for translations that are constructed from multiple parts.

**activate** (*language*)

Fetches the translation object for a given language and activates it as the current translation object for the current thread.

**deactivate** ()

Deactivates the currently active translation object so that further `_` calls will resolve against the default translation object, again.

**deactivate\_all** ()

Makes the active translation object a `NullTranslations()` instance. This is useful when we want delayed translations to appear as the original string for some reason.

**override** (*language, deactivate=False*)

A Python context manager that uses `django.utils.translation.activate()` to fetch the translation object for a given language, activates it as the translation object for the current thread and reactivates the previous active language on exit. Optionally, it can simply deactivate the temporary translation on exit with `django.utils.translation.deactivate()` if the `deactivate` argument is `True`. If you pass `None` as the language argument, a `NullTranslations()` instance is activated within the context.

`override` is also usable as a function decorator.

**check\_for\_language** (*lang\_code*)

Checks whether there is a global language file for the given language code (e.g. 'fr', 'pt\_BR'). This is used to decide whether a user-provided language is available.

**get\_language** ()

Returns the currently selected language code. Returns `None` if translations are temporarily deactivated (by `deactivate_all()` or when `None` is passed to `override()`).

**get\_language\_bidi** ()

Returns selected language's BiDi layout:

- `False` = left-to-right layout
- `True` = right-to-left layout

**get\_language\_from\_request** (*request, check\_path=False*)

Analyzes the request to find what language the user wants the system to show. Only languages listed in `settings.LANGUAGES` are taken into account. If the user requests a sublanguage where we have a main language, we send out the main language.

If `check_path` is `True`, the function first checks the requested URL for whether its path begins with a language code listed in the `LANGUAGES` setting.

**to\_locale** (*language*)

Turns a language name (en-us) into a locale name (en\_US).

**templatize** (*src*)

Turns a Django template into something that is understood by `xgettext`. It does so by translating the Django translation tags into standard `gettext` function invocations.

**LANGUAGE\_SESSION\_KEY**

Session key under which the active language for the current session is stored.

## 6.26 Validators

### 6.26.1 Writing validators

A validator is a callable that takes a value and raises a `ValidationError` if it doesn't meet some criteria. Validators can be useful for re-using validation logic between different types of fields.

For example, here's a validator that only allows even numbers:

```
from django.core.exceptions import ValidationError
from django.utils.translation import ugettext_lazy as _

def validate_even(value):
    if value % 2 != 0:
        raise ValidationError(
            _('%(value)s is not an even number'),
            params={'value': value},
        )
```

You can add this to a model field via the field's `validators` argument:

```
from django.db import models

class MyModel(models.Model):
    even_field = models.IntegerField(validators=[validate_even])
```

Because values are converted to Python before validators are run, you can even use the same validator with forms:

```
from django import forms

class MyForm(forms.Form):
    even_field = forms.IntegerField(validators=[validate_even])
```

You can also use a class with a `__call__()` method for more complex or configurable validators. `RegexValidator`, for example, uses this technique. If a class-based validator is used in the `validators` model field option, you should make sure it is *serializable by the migration framework* by adding `deconstruct()` and `__eq__()` methods.

### 6.26.2 How validators are run

See the *form validation* for more information on how validators are run in forms, and *Validating objects* for how they're run in models. Note that validators will not be run automatically when you save a model, but if you are

using a *ModelForm*, it will run your validators on any fields that are included in your form. See the *ModelForm documentation* for information on how model validation interacts with forms.

### 6.26.3 Built-in validators

The *django.core.validators* module contains a collection of callable validators for use with model and form fields. They're used internally but are available for use with your own fields, too. They can be used in addition to, or in lieu of custom `field.clean()` methods.

#### RegexValidator

```
class RegexValidator (regex=None, message=None, code=None, inverse_match=None, flags=0)
```

##### Parameters

- **regex** – If not `None`, overrides *regex*. Can be a regular expression string or a pre-compiled regular expression.
- **message** – If not `None`, overrides *message*.
- **code** – If not `None`, overrides *code*.
- **inverse\_match** – If not `None`, overrides *inverse\_match*.
- **flags** – If not `None`, overrides *flags*. In that case, *regex* must be a regular expression string, or `TypeError` is raised.

##### regex

The regular expression pattern to search for the provided *value*, or a pre-compiled regular expression. By default, raises a *ValidationError* with *message* and *code* if a match is not found. That standard behavior can be reversed by setting *inverse\_match* to `True`, in which case the *ValidationError* is raised when a match is found. By default, matches any string (including an empty string).

##### message

The error message used by *ValidationError* if validation fails. Defaults to "Enter a valid value".

##### code

The error code used by *ValidationError* if validation fails. Defaults to "invalid".

##### inverse\_match

The match mode for *regex*. Defaults to `False`.

##### flags

The flags used when compiling the regular expression string *regex*. If *regex* is a pre-compiled regular expression, and *flags* is overridden, `TypeError` is raised. Defaults to `0`.

#### EmailValidator

```
class EmailValidator (message=None, code=None, whitelist=None)
```

##### Parameters

- **message** – If not `None`, overrides *message*.
- **code** – If not `None`, overrides *code*.
- **whitelist** – If not `None`, overrides *whitelist*.

**message**

The error message used by *ValidationError* if validation fails. Defaults to "Enter a valid email address".

**code**

The error code used by *ValidationError* if validation fails. Defaults to "invalid".

**whitelist**

Whitelist of email domains to allow. By default, a regular expression (the `domain_regex` attribute) is used to validate whatever appears after the @ sign. However, if that string appears in the whitelist, this validation is bypassed. If not provided, the default whitelist is `['localhost']`. Other domains that don't contain a dot won't pass validation, so you'd need to whitelist them as necessary.

**URLValidator**

**class URLValidator** (*schemes=None, regex=None, message=None, code=None*)

A *RegexValidator* that ensures a value looks like a URL, and raises an error code of 'invalid' if it doesn't.

Loopback addresses and reserved IP spaces are considered valid. Literal IPv6 addresses ([RFC 2732](#)) and unicode domains are both supported.

In addition to the optional arguments of its parent *RegexValidator* class, *URLValidator* accepts an extra optional attribute:

**schemes**

URL/URI scheme list to validate against. If not provided, the default list is `['http', 'https', 'ftp', 'ftps']`. As a reference, the IANA website provides a full list of [valid URI schemes](#).

**validate\_email****validate\_email**

An *EmailValidator* instance without any customizations.

**validate\_slug****validate\_slug**

A *RegexValidator* instance that ensures a value consists of only letters, numbers, underscores or hyphens.

**validate\_unicode\_slug****validate\_unicode\_slug**

A *RegexValidator* instance that ensures a value consists of only Unicode letters, numbers, underscores, or hyphens.

**validate\_ipv4\_address****validate\_ipv4\_address**

A *RegexValidator* instance that ensures a value looks like an IPv4 address.

**validate\_ipv6\_address****validate\_ipv6\_address**

Uses `django.utils.ipv6` to check the validity of an IPv6 address.

**validate\_ipv46\_address****validate\_ipv46\_address**

Uses both `validate_ipv4_address` and `validate_ipv6_address` to ensure a value is either a valid IPv4 or IPv6 address.

**validate\_comma\_separated\_integer\_list****validate\_comma\_separated\_integer\_list**

A *RegexValidator* instance that ensures a value is a comma-separated list of integers.

**int\_list\_validator****int\_list\_validator** (*sep=' ', message=None, code='invalid', allow\_negative=False*)

Returns a *RegexValidator* instance that ensures a string consists of integers separated by *sep*. It allows negative integers when *allow\_negative* is `True`.

The *allow\_negative* parameter was added.

**MaxValueValidator****class MaxValueValidator** (*max\_value, message=None*)

Raises a *ValidationError* with a code of `'max_value'` if value is greater than *max\_value*.

**MinValueValidator****class MinValueValidator** (*min\_value, message=None*)

Raises a *ValidationError* with a code of `'min_value'` if value is less than *min\_value*.

**MaxLengthValidator****class MaxLengthValidator** (*max\_length, message=None*)

Raises a *ValidationError* with a code of `'max_length'` if the length of value is greater than *max\_length*.

**MinLengthValidator****class MinLengthValidator** (*min\_length, message=None*)

Raises a *ValidationError* with a code of `'min_length'` if the length of value is less than *min\_length*.

## DecimalValidator

**class** `DecimalValidator` (*max\_digits*, *decimal\_places*)

Raises `ValidationError` with the following codes:

- 'max\_digits' if the number of digits is larger than `max_digits`.
- 'max\_decimal\_places' if the number of decimals is larger than `decimal_places`.
- 'max\_whole\_digits' if the number of whole digits is larger than the difference between `max_digits` and `decimal_places`.

## 6.27 Built-in Views

Several of Django's built-in views are documented in *Writing views* as well as elsewhere in the documentation.

### 6.27.1 Serving files in development

`static.serve` (*request*, *path*, *document\_root*, *show\_indexes=False*)

There may be files other than your project's static assets that, for convenience, you'd like to have Django serve for you in local development. The `serve()` view can be used to serve any directory you give it. (This view is **not** hardened for production use and should be used only as a development aid; you should serve these files in production using a real front-end web server).

The most likely example is user-uploaded content in `MEDIA_ROOT`. `django.contrib.staticfiles` is intended for static assets and has no built-in handling for user-uploaded files, but you can have Django serve your `MEDIA_ROOT` by appending something like this to your URLconf:

```
from django.conf import settings
from django.views.static import serve

# ... the rest of your URLconf goes here ...

if settings.DEBUG:
    urlpatterns += [
        url(r'^media/(?P<path>.*)$', serve, {
            'document_root': settings.MEDIA_ROOT,
        }),
    ]
```

Note, the snippet assumes your `MEDIA_URL` has a value of  `'/media/'`. This will call the `serve()` view, passing in the path from the URLconf and the (required) `document_root` parameter.

Since it can become a bit cumbersome to define this URL pattern, Django ships with a small URL helper function `static()` that takes as parameters the prefix such as `MEDIA_URL` and a dotted path to a view, such as `'django.views.static.serve'`. Any other function parameter will be transparently passed to the view.

### 6.27.2 Error views

Django comes with a few views by default for handling HTTP errors. To override these with your own custom views, see *Customizing error views*.

## The 404 (page not found) view

```
defaults.page_not_found(request, exception, template_name='404.html')
```

When you raise `Http404` from within a view, Django loads a special view devoted to handling 404 errors. By default, it's the view `django.views.defaults.page_not_found()`, which either produces a very simple “Not Found” message or loads and renders the template `404.html` if you created it in your root template directory.

The default 404 view will pass two variables to the template: `request_path`, which is the URL that resulted in the error, and `exception`, which is a useful representation of the exception that triggered the view (e.g. containing any message passed to a specific `Http404` instance).

Three things to note about 404 views:

- The 404 view is also called if Django doesn't find a match after checking every regular expression in the URLconf.
- The 404 view is passed a `RequestContext` and will have access to variables supplied by your template context processors (e.g. `MEDIA_URL`).
- If `DEBUG` is set to `True` (in your settings module), then your 404 view will never be used, and your URLconf will be displayed instead, with some debug information.

The signature of `page_not_found()` changed. The function now accepts a second parameter, the exception that triggered the error. A useful representation of the exception is also passed in the template context.

Passing a nonexistent `template_name` will raise `TemplateDoesNotExist`.

## The 500 (server error) view

```
defaults.server_error(request, template_name='500.html')
```

Similarly, Django executes special-case behavior in the case of runtime errors in view code. If a view results in an exception, Django will, by default, call the view `django.views.defaults.server_error`, which either produces a very simple “Server Error” message or loads and renders the template `500.html` if you created it in your root template directory.

The default 500 view passes no variables to the `500.html` template and is rendered with an empty `Context` to lessen the chance of additional errors.

If `DEBUG` is set to `True` (in your settings module), then your 500 view will never be used, and the traceback will be displayed instead, with some debug information.

Passing a nonexistent `template_name` will raise `TemplateDoesNotExist`.

## The 403 (HTTP Forbidden) view

```
defaults.permission_denied(request, exception, template_name='403.html')
```

In the same vein as the 404 and 500 views, Django has a view to handle 403 Forbidden errors. If a view results in a 403 exception then Django will, by default, call the view `django.views.defaults.permission_denied`.

This view loads and renders the template `403.html` in your root template directory, or if this file does not exist, instead serves the text “403 Forbidden”, as per [RFC 7231#section-6.5.3](#) (the HTTP 1.1 Specification). The template context contains `exception`, which is the unicode representation of the exception that triggered the view.

`django.views.defaults.permission_denied` is triggered by a `PermissionDenied` exception. To deny access in a view you can use code like this:

```
from django.core.exceptions import PermissionDenied

def edit(request, pk):
    if not request.user.is_staff:
        raise PermissionDenied
    # ...
```

The signature of `permission_denied()` changed in Django 1.9. The function now accepts a second parameter, the exception that triggered the error. The unicode representation of the exception is also passed in the template context.

Passing a nonexistent `template_name` will raise `TemplateDoesNotExist`.

### The 400 (bad request) view

`defaults.bad_request` (*request, exception, template\_name='400.html'*)

When a *SuspiciousOperation* is raised in Django, it may be handled by a component of Django (for example resetting the session data). If not specifically handled, Django will consider the current request a ‘bad request’ instead of a server error.

`django.views.defaults.bad_request`, is otherwise very similar to the `server_error` view, but returns with the status code 400 indicating that the error condition was the result of a client operation. By default, nothing related to the exception that triggered the view is passed to the template context, as the exception message might contain sensitive information like filesystem paths.

`bad_request` views are also only used when `DEBUG` is `False`.

The signature of `bad_request()` changed in Django 1.9. The function now accepts a second parameter, the exception that triggered the error.

Passing a nonexistent `template_name` will raise `TemplateDoesNotExist`.

---

## Meta-documentation and miscellany

---

Documentation that we can't find a more organized place for. Like that drawer in your kitchen with the scissors, batteries, duct tape, and other junk.

### 7.1 API stability

Django promises API stability and forwards-compatibility since version 1.0. In a nutshell, this means that code you develop against a version of Django will continue to work with future releases. You may need to make minor changes when upgrading the version of Django your project uses: see the “Backwards incompatible changes” section of the *release note* for the version or versions to which you are upgrading.

#### 7.1.1 What “stable” means

In this context, stable means:

- All the public APIs (everything in this documentation) will not be moved or renamed without providing backwards-compatible aliases.
- If new features are added to these APIs – which is quite possible – they will not break or change the meaning of existing methods. In other words, “stable” does not (necessarily) mean “complete.”
- If, for some reason, an API declared stable must be removed or replaced, it will be declared deprecated but will remain in the API for at least two feature releases. Warnings will be issued when the deprecated method is called.

See *Official releases* for more details on how Django's version numbering scheme works, and how features will be deprecated.

- We'll only break backwards compatibility of these APIs if a bug or security hole makes it completely unavoidable.

## 7.1.2 Stable APIs

In general, everything covered in the documentation – with the exception of anything in the *internals area* is considered stable.

## 7.1.3 Exceptions

There are a few exceptions to this stability and backwards-compatibility promise.

### Security fixes

If we become aware of a security problem – hopefully by someone following our *security reporting policy* – we’ll do everything necessary to fix it. This might mean breaking backwards compatibility; security trumps the compatibility guarantee.

### APIs marked as internal

Certain APIs are explicitly marked as “internal” in a couple of ways:

- Some documentation refers to internals and mentions them as such. If the documentation says that something is internal, we reserve the right to change it.
- Functions, methods, and other objects prefixed by a leading underscore (`_`). This is the standard Python way of indicating that something is private; if any method starts with a single `_`, it’s an internal API.

## 7.2 Design philosophies

This document explains some of the fundamental philosophies Django’s developers have used in creating the framework. Its goal is to explain the past and guide the future.

### 7.2.1 Overall

#### Loose coupling

A fundamental goal of Django’s stack is *loose coupling and tight cohesion*. The various layers of the framework shouldn’t “know” about each other unless absolutely necessary.

For example, the template system knows nothing about Web requests, the database layer knows nothing about data display and the view system doesn’t care which template system a programmer uses.

Although Django comes with a full stack for convenience, the pieces of the stack are independent of another wherever possible.

#### Less code

Django apps should use as little code as possible; they should lack boilerplate. Django should take full advantage of Python’s dynamic capabilities, such as introspection.

## Quick development

The point of a Web framework in the 21st century is to make the tedious aspects of Web development fast. Django should allow for incredibly quick Web development.

## Don't repeat yourself (DRY)

Every distinct concept and/or piece of data should live in one, and only one, place. Redundancy is bad. Normalization is good.

The framework, within reason, should deduce as much as possible from as little as possible.

### See also:

The [discussion of DRY on the Portland Pattern Repository](#)

## Explicit is better than implicit

This is a core Python principle listed in [PEP 20](#), and it means Django shouldn't do too much "magic." Magic shouldn't happen unless there's a really good reason for it. Magic is worth using only if it creates a huge convenience unattainable in other ways, and it isn't implemented in a way that confuses developers who are trying to learn how to use the feature.

## Consistency

The framework should be consistent at all levels. Consistency applies to everything from low-level (the Python coding style used) to high-level (the "experience" of using Django).

## 7.2.2 Models

### Explicit is better than implicit

Fields shouldn't assume certain behaviors based solely on the name of the field. This requires too much knowledge of the system and is prone to errors. Instead, behaviors should be based on keyword arguments and, in some cases, on the type of the field.

### Include all relevant domain logic

Models should encapsulate every aspect of an "object," following Martin Fowler's [Active Record](#) design pattern.

This is why both the data represented by a model and information about it (its human-readable name, options like default ordering, etc.) are defined in the model class; all the information needed to understand a given model should be stored *in* the model.

## 7.2.3 Database API

The core goals of the database API are:

## SQL efficiency

It should execute SQL statements as few times as possible, and it should optimize statements internally.

This is why developers need to call `save()` explicitly, rather than the framework saving things behind the scenes silently.

This is also why the `select_related()` `QuerySet` method exists. It’s an optional performance booster for the common case of selecting “every related object.”

## Terse, powerful syntax

The database API should allow rich, expressive statements in as little syntax as possible. It should not rely on importing other modules or helper objects.

Joins should be performed automatically, behind the scenes, when necessary.

Every object should be able to access every related object, systemwide. This access should work both ways.

## Option to drop into raw SQL easily, when needed

The database API should realize it’s a shortcut but not necessarily an end-all-be-all. The framework should make it easy to write custom SQL – entire statements, or just custom `WHERE` clauses as custom parameters to API calls.

## 7.2.4 URL design

### Loose coupling

URLs in a Django app should not be coupled to the underlying Python code. Tying URLs to Python function names is a Bad And Ugly Thing.

Along these lines, the Django URL system should allow URLs for the same app to be different in different contexts. For example, one site may put stories at `/stories/`, while another may use `/news/`.

### Infinite flexibility

URLs should be as flexible as possible. Any conceivable URL design should be allowed.

### Encourage best practices

The framework should make it just as easy (or even easier) for a developer to design pretty URLs than ugly ones.

File extensions in Web-page URLs should be avoided.

Vignette-style commas in URLs deserve severe punishment.

### Definitive URLs

Technically, `foo.com/bar` and `foo.com/bar/` are two different URLs, and search-engine robots (and some Web traffic-analyzing tools) would treat them as separate pages. Django should make an effort to “normalize” URLs so that search-engine robots don’t get confused.

This is the reasoning behind the `APPEND_SLASH` setting.

## 7.2.5 Template system

### Separate logic from presentation

We see a template system as a tool that controls presentation and presentation-related logic – and that’s it. The template system shouldn’t support functionality that goes beyond this basic goal.

### Discourage redundancy

The majority of dynamic websites use some sort of common sitewide design – a common header, footer, navigation bar, etc. The Django template system should make it easy to store those elements in a single place, eliminating duplicate code.

This is the philosophy behind *template inheritance*.

### Be decoupled from HTML

The template system shouldn’t be designed so that it only outputs HTML. It should be equally good at generating other text-based formats, or just plain text.

### XML should not be used for template languages

Using an XML engine to parse templates introduces a whole new world of human error in editing templates – and incurs an unacceptable level of overhead in template processing.

### Assume designer competence

The template system shouldn’t be designed so that templates necessarily are displayed nicely in WYSIWYG editors such as Dreamweaver. That is too severe of a limitation and wouldn’t allow the syntax to be as nice as it is. Django expects template authors are comfortable editing HTML directly.

### Treat whitespace obviously

The template system shouldn’t do magic things with whitespace. If a template includes whitespace, the system should treat the whitespace as it treats text – just display it. Any whitespace that’s not in a template tag should be displayed.

### Don’t invent a programming language

The goal is not to invent a programming language. The goal is to offer just enough programming-esque functionality, such as branching and looping, that is essential for making presentation-related decisions. The *Django Template Language (DTL)* aims to avoid advanced logic.

The Django template system recognizes that templates are most often written by *designers*, not *programmers*, and therefore should not assume Python knowledge.

### Safety and security

The template system, out of the box, should forbid the inclusion of malicious code – such as commands that delete database records.

This is another reason the template system doesn’t allow arbitrary Python code.

## Extensibility

The template system should recognize that advanced template authors may want to extend its technology. This is the philosophy behind custom template tags and filters.

## 7.2.6 Views

### Simplicity

Writing a view should be as simple as writing a Python function. Developers shouldn't have to instantiate a class when a function will do.

### Use request objects

Views should have access to a request object – an object that stores metadata about the current request. The object should be passed directly to a view function, rather than the view function having to access the request data from a global variable. This makes it light, clean and easy to test views by passing in “fake” request objects.

### Loose coupling

A view shouldn't care about which template system the developer uses – or even whether a template system is used at all.

### Differentiate between GET and POST

GET and POST are distinct; developers should explicitly use one or the other. The framework should make it easy to distinguish between GET and POST data.

## 7.2.7 Cache Framework

The core goals of Django's *cache framework* are:

### Less code

A cache should be as fast as possible. Hence, all framework code surrounding the cache backend should be kept to the absolute minimum, especially for `get()` operations.

### Consistency

The cache API should provide a consistent interface across the different cache backends.

### Extensibility

The cache API should be extensible at the application level based on the developer's needs (for example, see *Cache key transformation*).

## 7.3 Third-party distributions of Django

Many third-party distributors are now providing versions of Django integrated with their package-management systems. These can make installation and upgrading much easier for users of Django since the integration includes the ability to automatically install dependencies (like database adapters) that Django requires.

Typically, these packages are based on the latest stable release of Django, so if you want to use the development version of Django you'll need to follow the instructions for *installing the development version* from our Git repository.

If you're using Linux or a Unix installation, such as OpenSolaris, check with your distributor to see if they already package Django. If you're using a Linux distro and don't know how to find out if a package is available, then now is a good time to learn. The Django Wiki contains a list of [Third Party Distributions](#) to help you out.

### 7.3.1 For distributors

If you'd like to package Django for distribution, we'd be happy to help out! Please join the *django-developers* mailing list and introduce yourself.

We also encourage all distributors to subscribe to the *django-announce* mailing list, which is a (very) low-traffic list for announcing new releases of Django and important bugfixes.

**concrete model** A non-abstract (*abstract=False*) model.

**field** An attribute on a *model*; a given field usually maps directly to a single database column.

See *Models*.

**generic view** A higher-order *view* function that provides an abstract/generic implementation of a common idiom or pattern found in view development.

See *Class-based views*.

**model** Models store your application’s data.

See *Models*.

**MTV** “Model-template-view”; a software pattern, similar in style to MVC, but a better description of the way Django does things.

See *the FAQ entry*.

**MVC** Model-view-controller; a software pattern. Django *follows MVC to some extent*.

**project** A Python package – i.e. a directory of code – that contains all the settings for an instance of Django. This would include database configuration, Django-specific options and application-specific settings.

**property** Also known as “managed attributes”, and a feature of Python since version 2.2. This is a neat way to implement attributes whose usage resembles attribute access, but whose implementation uses method calls.

See *property*.

**queryset** An object representing some set of rows to be fetched from the database.

See *Making queries*.

**slug** A short label for something, containing only letters, numbers, underscores or hyphens. They’re generally used in URLs. For example, in a typical blog entry URL:

```
https://www.djangoproject.com/weblog/2008/apr/12/spring/
```

the last bit (*spring*) is the slug.

**template** A chunk of text that acts as formatting for representing data. A template helps to abstract the presentation of data from the data itself.

See *Templates*.

**view** A function responsible for rendering a page.

Release notes for the official Django releases. Each release note will tell you what's new in each version, and will also describe any backwards-incompatible changes made in that version.

For those *upgrading to a new version of Django*, you will need to check all the backwards-incompatible changes and *deprecated features* for each 'final' release from the one after your current Django version, up to and including the new version.

## 9.1 Final releases

Below are release notes through Django 1.10 and its patch releases. Newer versions of the documentation contain the release notes for any later releases.

### 9.1.1 1.10 release

#### Django 1.10.8 release notes

*September 5, 2017*

Django 1.10.8 fixes a security issue in 1.10.7.

#### **CVE-2017-12794: Possible XSS in traceback section of technical 500 debug page**

In older versions, HTML autoescaping was disabled in a portion of the template for the technical 500 debug page. Given the right circumstances, this allowed a cross-site scripting attack. This vulnerability shouldn't affect most production sites since you shouldn't run with `DEBUG = True` (which makes this page accessible) in your production settings.

## Django 1.10.7 release notes

April 4, 2017

Django 1.10.7 fixes two security issues and a bug in 1.10.6.

### CVE-2017-7233: Open redirect and possible XSS attack via user-supplied numeric redirect URLs

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()` and `il8n`) to redirect the user to an “on success” URL. The security check for these redirects (namely `django.utils.http.is_safe_url()`) considered some numeric URLs (e.g. `http:999999999`) “safe” when they shouldn’t be.

Also, if a developer relies on `is_safe_url()` to provide safe redirect targets and puts such a URL into a link, they could suffer from an XSS attack.

### CVE-2017-7234: Open redirect vulnerability in `django.views.static.serve()`

A maliciously crafted URL to a Django site using the `serve()` view could redirect to any other domain. The view no longer does any redirects as they don’t provide any known, useful functionality.

Note, however, that this view has always carried a warning that it is not hardened for production use and should be used only as a development aid.

## Bugfixes

- Made `admin’s RelatedFieldWidgetWrapper` use the wrapped widget’s `value_omitted_from_data()` method (#27905).
- Fixed model form default fallback for `SelectMultiple` (#27993).

## Django 1.10.6 release notes

March 1, 2017

Django 1.10.6 fixes several bugs in 1.10.5.

## Bugfixes

- Fixed `ClearableFileInput’s “Clear”` checkbox on model form fields where the model field has a default (#27805).
- Fixed `RequestDataTooBig` and `TooManyFieldsSent` exceptions crashing rather than generating a bad request response (#27820).
- Fixed a crash on Oracle and PostgreSQL when subtracting `DurationField` or `IntegerField` from `DateField` (#27828).
- Fixed query expression date subtraction accuracy on PostgreSQL for differences larger than a month (#27856).
- Fixed a `GDALException` raised by `GDALClose` on `GDAL ≥ 2.0` (#27479).

## Django 1.10.5 release notes

January 4, 2017

Django 1.10.5 fixes several bugs in 1.10.4.

### Bugfixes

- Fixed a crash in the debug view if `request.user` can't be retrieved, such as if the database is unavailable (#27567).
- Fixed occasional missing plural forms in `JavaScriptCatalog` (#27418).
- Fixed a regression in the `timesince` and `timeuntil` filters that caused incorrect results for dates in a leap year (#27637).
- Fixed a regression where `collectstatic` overwrote newer files in remote storages (#27658).

## Django 1.10.4 release notes

December 1, 2016

Django 1.10.4 fixes several bugs in 1.10.3.

### Bugfixes

- Quoted the Oracle test user's password in queries to fix the "ORA-00922: missing or invalid option" error when the password starts with a number or special character (#27420).
- Fixed incorrect `app_label / model_name` arguments for `allow_migrate()` in `makemigrations` migration consistency checks (#27461).
- Made `Model.delete(keep_parents=True)` preserve parent reverse relationships in multi-table inheritance (#27407).
- Fixed a `QuerySet.update()` crash on SQLite when updating a `DateTimeField` with an `F()` expression and a `timedelta` (#27544).
- Prevented `LocaleMiddleware` from redirecting on URLs that should return 404 when using `prefix_default_language=False` (#27402).
- Prevented an unnecessary index from being created on an InnoDB `ForeignKey` when the field was added after the model was created (#27558).

## Django 1.10.3 release notes

November 1, 2016

Django 1.10.3 fixes two security issues and several bugs in 1.10.2.

### User with hardcoded password created when running tests on Oracle

When running tests with an Oracle database, Django creates a temporary database user. In older versions, if a password isn't manually specified in the database settings `TEST` dictionary, a hardcoded password is used. This could allow an attacker with network access to the database server to connect.

This user is usually dropped after the test suite completes, but not when using the `manage.py test --keepdb` option or if the user has an active session (such as an attacker's connection).

A randomly generated password is now used for each test run.

## DNS rebinding vulnerability when `DEBUG=True`

Older versions of Django don't validate the `Host` header against `settings.ALLOWED_HOSTS` when `settings.DEBUG=True`. This makes them vulnerable to a [DNS rebinding attack](#).

While Django doesn't ship a module that allows remote code execution, this is at least a cross-site scripting vector, which could be quite serious if developers load a copy of the production database in development or connect to some production services for which there's no development instance, for example. If a project uses a package like the `django-debug-toolbar`, then the attacker could execute arbitrary SQL, which could be especially bad if the developers connect to the database with a superuser account.

`settings.ALLOWED_HOSTS` is now validated regardless of `DEBUG`. For convenience, if `ALLOWED_HOSTS` is empty and `DEBUG=True`, the following variations of `localhost` are allowed `['localhost', '127.0.0.1', '::1']`. If your local settings file has your production `ALLOWED_HOSTS` value, you must now omit it to get those fallback values.

## Bugfixes

- Allowed `User.is_authenticated` and `User.is_anonymous` properties to be tested for set membership (#27309).
- Fixed a performance regression when running `migrate` in projects with `RenameModel` operations (#27279).
- Added `model_name` to the `allow_migrate()` calls in `makemigrations` (#27200).
- Made the `JavaScriptCatalog` view respect the `packages` argument; previously it was ignored (#27374).
- Fixed `QuerySet.bulk_create()` on PostgreSQL when the number of objects is a multiple plus one of `batch_size` (#27385).
- Prevented `i18n_patterns()` from using too much of the URL as the language to fix a use case for `prefix_default_language=False` (#27063).
- Replaced a possibly incorrect redirect from `SessionMiddleware` when a session is destroyed in a concurrent request with a `SuspiciousOperation` to indicate that the request can't be completed (#27363).

## Django 1.10.2 release notes

*October 1, 2016*

Django 1.10.2 fixes several bugs in 1.10.1.

## Bugfixes

- Fixed a crash in MySQL database validation where `SELECT @@sql_mode` doesn't return a result (#27180).
- Allowed combining `contrib.postgres.search.SearchQuery` with more than one `&` or `|` operators (#27143).
- Disabled system check for URL patterns beginning with a `'/` when `APPEND_SLASH=False` (#27238).

- Fixed model form default fallback for `CheckboxSelectMultiple`, `MultiWidget`, `FileInput`, `SplitDateTimeWidget`, `SelectDateWidget`, and `SplitArrayWidget` (#27186). Custom widgets affected by this issue should implement `value_omitted_from_data()`.
- Fixed a crash in `runserver` logging during a “Broken pipe” error (#27271).
- Fixed a regression where unchanged localized date/time fields were listed as changed in the admin’s model history messages (#27302).

## Django 1.10.1 release notes

*September 1, 2016*

Django 1.10.1 fixes several bugs in 1.10.

### Bugfixes

- Fixed a crash in MySQL connections where `SELECT @@SQL_AUTO_IS_NULL` doesn’t return a result (#26991).
- Allowed `User.is_authenticated` and `User.is_anonymous` properties to be compared using `==`, `!=`, and `|` (#26988, #27154).
- Removed the broken `BaseCommand.usage()` method which was for `optparse` support (#27000).
- Fixed a checks framework crash with an empty `Meta.default_permissions` (#26997).
- Fixed a regression in the number of queries when using `RadioSelect` with a `ModelChoiceField` form field (#27001).
- Fixed a crash if `request.META['CONTENT_LENGTH']` is an empty string (#27005).
- Fixed the `isnull` lookup on a `ForeignKey` with its `to_field` pointing to a `CharField` or pointing to a `CharField` defined with `primary_key=True` (#26983).
- Prevented the `migrate` command from raising `InconsistentMigrationHistory` in the presence of unapplied squashed migrations (#27004).
- Fixed a regression in `Client.force_login()` which required specifying a backend rather than automatically using the first one if multiple backends are configured (#27027).
- Made `QuerySet.bulk_create()` properly initialize model instances on backends, such as PostgreSQL, that support returning the IDs of the created records so that many-to-many relationships can be used on the new objects (#27026).
- Fixed crash of `django.views.static.serve()` with `show_indexes` enabled (#26973).
- Fixed `ClearableFileInput` to avoid the required `HTML` attribute when initial data exists (#27037).
- Fixed annotations with database functions when combined with lookups on PostGIS (#27014).
- Reallowed the `{% for %}` tag to unpack any iterable (#27058).
- Made `makemigrations` skip inconsistent history checks on non-default databases if database routers aren’t in use or if no apps can be migrated to the database (#27054, #27110, #27142).
- Removed duplicated managers in `Model._meta.managers` (#27073).
- Fixed `contrib.admindocs` crash when a view is in a class, such as some of the admin views (#27018).

- Reverted a few admin checks that checked `field.many_to_many` back to `isinstance(field, models.ManyToManyField)` since it turned out the checks weren't suitable to be generalized like that (#26998).
- Added the database alias to the `InconsistentMigrationHistory` message raised by `makemigrations` and `migrate` (#27089).
- Fixed the creation of `ContentType` and `Permission` objects for models of applications without migrations when calling the `migrate` command with no migrations to apply (#27044).
- Included the already applied migration state changes in the `Apps` instance provided to the `pre_migrate` signal receivers to allow `ContentType` renaming to be performed on model rename (#27100).
- Reallowed subclassing `UserCreationForm` without `USERNAME_FIELD` in `Meta.fields` (#27111).
- Fixed a regression in model forms where model fields with a default that didn't appear in POST data no longer used the default (#27039).

### Django 1.10 release notes

August 1, 2016

Welcome to Django 1.10!

These release notes cover the *new features*, as well as some *backwards incompatible changes* you'll want to be aware of when upgrading from Django 1.9 or older versions. We've *dropped some features* that have reached the end of their deprecation cycle, and we've *begun the deprecation process for some features*.

See the *Upgrading Django to a newer version* guide if you're updating an existing project.

### Python compatibility

Like Django 1.9, Django 1.10 requires Python 2.7, 3.4, or 3.5. We **highly recommend** and only officially support the latest release of each series.

### What's new in Django 1.10

#### Full text search for PostgreSQL

`django.contrib.postgres` now includes a *collection of database functions* to allow the use of the full text search engine. You can search across multiple fields in your relational database, combine the searches with other lookups, use different language configurations and weightings, and rank the results by relevance.

It also now includes trigram support, using the `trigram_similar` lookup, and the `TrigramSimilarity` and `TrigramDistance` expressions.

#### New-style middleware

*A new style of middleware is introduced* to solve the lack of strict request/response layering of the old-style of middleware described in [DEP 0005](#). You'll need to *adapt old, custom middleware* and switch from the `MIDDLEWARE_CLASSES` setting to the new `MIDDLEWARE` setting to take advantage of the improvements.

## Official support for Unicode usernames

The `User` model in `django.contrib.auth` originally only accepted ASCII letters in usernames. Although it wasn't a deliberate choice, Unicode characters have always been accepted when using Python 3.

The username validator now explicitly accepts Unicode letters by default on Python 3 only.

Custom user models may use the new `ASCIIXUsernameValidator` or `UnicodeUsernameValidator`.

## Minor features

### `django.contrib.admin`

- For sites running on a subpath, the default *URL for the "View site" link* at the top of each admin page will now point to `request.META['SCRIPT_NAME']` if set, instead of `/`.
- The success message that appears after adding or editing an object now contains a link to the object's change form.
- All inline JavaScript is removed so you can enable the `Content-Security-Policy` HTTP header if you wish.
- The new `InlineModelAdmin.classes` attribute allows specifying classes on inline fieldsets. Inlines with a `collapse` class will be initially collapsed and their header will have a small "show" link.
- If a user doesn't have the add permission, the `object-tools` block on a model's changelist will now be rendered (without the add button, of course). This makes it easier to add custom tools in this case.
- The `LogEntry` model now stores change messages in a JSON structure so that the message can be dynamically translated using the current active language. A new `LogEntry.get_change_message()` method is now the preferred way of retrieving the change message.
- Selected objects for fields in `ModelAdmin.raw_id_fields` now have a link to object's change form.
- Added "No date" and "Has date" choices for `DateFieldListFilter` if the field is nullable.
- The jQuery library embedded in the admin is upgraded from version 2.1.4 to 2.2.3.

### `django.contrib.auth`

- Added support for the *Argon2 password hash*. It's recommended over PBKDF2, however, it's not the default as it requires a third-party library.
- The default iteration count for the PBKDF2 password hasher has been increased by 25%. This backwards compatible change will not affect users who have subclassed `django.contrib.auth.hashers.PBKDF2PasswordHasher` to change the default value.
- The `logout()` view sends "no-cache" headers to prevent an issue where Safari caches redirects and prevents a user from being able to log out.
- Added the optional `backend` argument to `login()` to allow using it without credentials.
- The new `LOGOUT_REDIRECT_URL` setting controls the redirect of the `logout()` view, if the view doesn't get a `next_page` argument.
- The new `redirect_authenticated_user` parameter for the `login()` view allows redirecting authenticated users visiting the login page.

- The new `AllowAllUsersModelBackend` and `AllowAllUsersRemoteUserBackend` ignore the value of `User.is_active`, while `ModelBackend` and `RemoteUserBackend` now reject inactive users.

### `django.contrib.gis`

- `Distance lookups` now accept expressions as the distance value parameter.
- The new `GEOSGeometry.unary_union` property computes the union of all the elements of this geometry.
- Added the `GEOSGeometry.covers()` binary predicate.
- Added the `GDALBand.statistics()` method and `mean` and `std` attributes.
- Added support for the `MakeLine` aggregate and `GeoHash` function on Spatialite.
- Added support for the `Difference`, `Intersection`, and `SymDifference` functions on MySQL.
- Added support for instantiating empty GEOS geometries.
- The new `trim` and `precision` properties of `WKTWriter` allow controlling output of the fractional part of the coordinates in WKT.
- Added the `LineString.closed` and `MultiLineString.closed` properties.
- The `GeoJSON serializer` now outputs the primary key of objects in the `properties` dictionary if specific fields aren't specified.
- The ability to replicate input data on the `GDALBand.data()` method was added. Band data can now be updated with repeated values efficiently.
- Added database functions `IsValid` and `MakeValid`, as well as the `isvalid` lookup, all for PostGIS. This allows filtering and repairing invalid geometries on the database side.
- Added raster support for all `spatial lookups`.

### `django.contrib.postgres`

- For convenience, `HStoreField` now casts its keys and values to strings.

### `django.contrib.sessions`

- The `clearsessions` management command now removes file-based sessions.

### `django.contrib.sites`

- The `Site` model now supports `natural keys`.

### `django.contrib.staticfiles`

- The `static` template tag now uses `django.contrib.staticfiles` if it's in `INSTALLED_APPS`. This is especially useful for third-party apps which can now always use `{% load static %}` (instead of `{% load staticfiles %}` or `{% load static from staticfiles %}`) and not worry about whether or not the `staticfiles` app is installed.
- You can *more easily customize* the `collectstatic --ignore` option with a custom `AppConfig`.

## Cache

- The file-based cache backend now uses the highest pickling protocol.

## CSRF

- The default `CSRF_FAILURE_VIEW`, `views.csrf.csrf_failure()` now accepts an optional `template_name` parameter, defaulting to `'403_csrf.html'`, to control the template used to render the page.
- To protect against **BREACH** attacks, the CSRF protection mechanism now changes the form token value on every request (while keeping an invariant secret which can be used to validate the different tokens).

## Database backends

- Temporal data subtraction was unified on all backends.
- If the database supports it, backends can set `DatabaseFeatures.can_return_ids_from_bulk_insert=True` and implement `DatabaseOperations.fetch_returned_insert_ids()` to set primary keys on objects created using `QuerySet.bulk_create()`.
- Added keyword arguments to the `as_sql()` methods of various expressions (`Func`, `When`, `Case`, and `OrderBy`) to allow database backends to customize them without mutating `self`, which isn't safe when using different database backends. See the `arg_joiner` and `**extra_context` parameters of `Func.as_sql()` for an example.

## File Storage

- Storage backends now present a timezone-aware API with new methods `get_accessed_time()`, `get_created_time()`, and `get_modified_time()`. They return a timezone-aware datetime if `USE_TZ` is `True` and a naive datetime in the local timezone otherwise.
- The new `Storage.generate_filename()` method makes it easier to implement custom storages that don't use the `os.path` calls previously in `FileField`.

## Forms

- Form and widget `Media` is now served using `django.contrib.staticfiles` if installed.
- The `<input>` tag rendered by `CharField` now includes a `minlength` attribute if the field has a `min_length`.
- Required form fields now have the required HTML attribute. Set the new `Form.use_required_attribute` attribute to `False` to disable it. The required attribute isn't included on forms of formsets because the browser validation may not be correct when adding and deleting formsets.

## Generic Views

- The `View` class can now be imported from `django.views`.

## Internationalization

- The `il8n_patterns()` helper function can now be used in a root `URLConf` specified using `request.urlconf`.
- By setting the new `prefix_default_language` parameter for `il8n_patterns()` to `False`, you can allow accessing the default language without a URL prefix.
- `set_language()` now returns a 204 status code (No Content) for AJAX requests when there is no next parameter in POST or GET.
- The `JavaScriptCatalog` and `JSONCatalog` class-based views supersede the deprecated `javascript_catalog()` and `json_catalog()` function-based views. The new views are almost equivalent to the old ones except that by default the new views collect all JavaScript strings in the `djangojs` translation domain from all installed apps rather than only the JavaScript strings from `LOCALE_PATHS`.

## Management Commands

- `call_command()` now returns the value returned from the `command.handle()` method.
- The new `check --fail-level` option allows specifying the message level that will cause the command to exit with a non-zero status.
- The new `makemigrations --check` option makes the command exit with a non-zero status when model changes without migrations are detected.
- `makemigrations` now displays the path to the migration files that it generates.
- The `shell --interface` option now accepts `python` to force use of the “plain” Python interpreter.
- The new `shell --command` option lets you run a command as Django and exit, instead of opening the interactive shell.
- Added a warning to `dumpdata` if a proxy model is specified (which results in no output) without its concrete parent.
- The new `BaseCommand.requires_migrations_checks` attribute may be set to `True` if you want your command to print a warning, like `runserver` does, if the set of migrations on disk don’t match the migrations in the database.
- To assist with testing, `call_command()` now accepts a command object as the first argument.
- The `shell` command supports tab completion on systems using `libedit`, e.g. Mac OSX.
- The `inspectdb` command lets you choose what tables should be inspected by specifying their names as arguments.

## Migrations

- Added support for serialization of `enum.Enum` objects.
- Added the `elidable` argument to the `RunSQL` and `RunPython` operations to allow them to be removed when squashing migrations.
- Added support for *non-atomic migrations* by setting the `atomic` attribute on a `Migration`.
- The `migrate` and `makemigrations` commands now *check for a consistent migration history*. If they find some unapplied dependencies of an applied migration, `InconsistentMigrationHistory` is raised.
- The `pre_migrate()` and `post_migrate()` signals now dispatch their migration plan and apps.

## Models

- Reverse foreign keys from proxy models are now propagated to their concrete class. The reverse relation attached by a *ForeignKey* pointing to a proxy model is now accessible as a descriptor on the proxied model class and may be referenced in queryset filtering.
- The new *Field.rel\_db\_type()* method returns the database column data type for fields such as *ForeignKey* and *OneToOneField* that point to another field.
- The *arity* class attribute is added to *Func*. This attribute can be used to set the number of arguments the function accepts.
- Added *BigAutoField* which acts much like an *AutoField* except that it is guaranteed to fit numbers from 1 to 9223372036854775807.
- *QuerySet.in\_bulk()* may be called without any arguments to return all objects in the queryset.
- *related\_query\_name* now supports app label and class interpolation using the `'%(app_label)s'` and `'%(class)s'` strings.
- Allowed overriding model fields inherited from abstract base classes.
- The *prefetch\_related\_objects()* function is now a public API.
- *QuerySet.bulk\_create()* sets the primary key on objects when using PostgreSQL.
- Added the *Cast* database function.
- A proxy model may now inherit multiple proxy models that share a common non-abstract parent class.
- Added *Extract* functions to extract datetime components as integers, such as year and hour.
- Added *Trunc* functions to truncate a date or datetime to a significant component. They enable queries like sales-per-day or sales-per-hour.
- *Model.\_\_init\_\_()* now sets values of virtual fields from its keyword arguments.
- The new *Meta.base\_manager\_name* and *Meta.default\_manager\_name* options allow controlling the *\_base\_manager* and *\_default\_manager*, respectively.

## Requests and Responses

- Added *request.user* to the debug view.
- Added *HttpResponse* methods *readable()* and *seekable()* to make an instance a stream-like object and allow wrapping it with *io.TextIOWrapper*.
- Added the *HttpRequest.content\_type* and *content\_params* attributes which are parsed from the *CONTENT\_TYPE* header.
- The parser for *request.COOKIES* is simplified to better match the behavior of browsers. *request.COOKIES* may now contain cookies that are invalid according to [RFC 6265](#) but are possible to set via *document.cookie*.

## Serialization

- The *django.core.serializers.json.DjangoJSONEncoder* now knows how to serialize lazy strings, typically used for translatable content.

## Templates

- Added the `autoescape` option to the `DjangoTemplates` backend and the `Engine` class.
- Added the `is` and `is not` comparison operators to the `if` tag.
- Allowed `dictsort` to order a list of lists by an element at a specified index.
- The `debug()` context processor contains queries for all database aliases instead of only the default alias.
- Added relative path support for string arguments of the `extends` and `include` template tags.

## Tests

- To better catch bugs, `TestCase` now checks deferrable database constraints at the end of each test.
- Tests and test cases can be *marked with tags* and run selectively with the new `test --tag` and `test --exclude-tag` options.
- You can now login and use sessions with the test client even if `django.contrib.sessions` is not in `INSTALLED_APPS`.

## URLs

- An addition in `django.setup()` allows URL resolving that happens outside of the request/response cycle (e.g. in management commands and standalone scripts) to take `FORCE_SCRIPT_NAME` into account when it is set.

## Validators

- `URLValidator` now limits the length of domain name labels to 63 characters and the total length of domain names to 253 characters per [RFC 1034](#).
- `int_list_validator()` now accepts an optional `allow_negative` boolean parameter, defaulting to `False`, to allow negative integers.

## Backwards incompatible changes in 1.10

**Warning:** In addition to the changes outlined in this section, be sure to review the [Features removed in 1.10](#) for the features that have reached the end of their deprecation cycle and therefore been removed. If you haven't updated your code within the deprecation timeline for a given feature, its removal may appear as a backwards incompatible change.

## Database backend API

- GIS's `AreaField` uses an unspecified underlying numeric type that could in practice be any numeric Python type. `decimal.Decimal` values retrieved from the database are now converted to `float` to make it easier to combine them with values used by the GIS libraries.

- In order to enable temporal subtraction you must set the `supports_temporal_subtraction` database feature flag to `True` and implement the `DatabaseOperations.subtract_temporals()` method. This method should return the SQL and parameters required to compute the difference in microseconds between the `lhs` and `rhs` arguments in the datatype used to store `DurationField`.

### `select_related()` prohibits non-relational fields for nested relations

Django 1.8 added validation for non-relational fields in `select_related()`:

```
>>> Book.objects.select_related('title')
Traceback (most recent call last):
...
FieldError: Non-relational field given in select_related: 'title'
```

But it didn't prohibit nested non-relation fields as it does now:

```
>>> Book.objects.select_related('author__name')
Traceback (most recent call last):
...
FieldError: Non-relational field given in select_related: 'name'
```

### `_meta.get_fields()` returns consistent reverse fields for proxy models

Before Django 1.10, the `get_fields()` method returned different reverse fields when called on a proxy model compared to its proxied concrete class. This inconsistency was fixed by returning the full set of fields pointing to a concrete class or one of its proxies in both cases.

### `AbstractUser.username` `max_length` increased to 150

A migration for `django.contrib.auth.models.User.username` is included. If you have a custom user model inheriting from `AbstractUser`, you'll need to generate and apply a database migration for your user model.

We considered an increase to 254 characters to more easily allow the use of email addresses (which are limited to 254 characters) as usernames but rejected it due to a MySQL limitation. When using the `utf8mb4` encoding (recommended for proper Unicode support), MySQL can only create unique indexes with 191 characters by default. Therefore, if you need a longer length, please use a custom user model.

If you want to preserve the 30 character limit for usernames, use a custom form when creating a user or changing usernames:

```
from django.contrib.auth.forms import UserCreationForm

class MyUserCreationForm(UserCreationForm):
    username = forms.CharField(
        max_length=30,
        help_text='Required. 30 characters or fewer. Letters, digits and @/./+/-/_
↪only.',
    )
```

If you wish to keep this restriction in the admin, set `UserAdmin.add_form` to use this form:

```
from django.contrib.auth.admin import UserAdmin as BaseUserAdmin
from django.contrib.auth.models import User
```

```
class UserAdmin(BaseUserAdmin):
    add_form = MyUserCreationForm

admin.site.unregister(User)
admin.site.register(User, UserAdmin)
```

## Dropped support for PostgreSQL 9.1

Upstream support for PostgreSQL 9.1 ends in September 2016. As a consequence, Django 1.10 sets PostgreSQL 9.2 as the minimum version it officially supports.

## runserver output goes through logging

Request and response handling of the `runserver` command is sent to the `django.server` logger instead of to `sys.stderr`. If you disable Django's logging configuration or override it with your own, you'll need to add the appropriate logging configuration if you want to see that output:

```
'formatters': {
    'django.server': {
        '()': 'django.utils.log.ServerFormatter',
        'format': '[%(server_time)s] %(message)s',
    }
},
'handlers': {
    'django.server': {
        'level': 'INFO',
        'class': 'logging.StreamHandler',
        'formatter': 'django.server',
    },
},
'loggers': {
    'django.server': {
        'handlers': ['django.server'],
        'level': 'INFO',
        'propagate': False,
    }
}
```

## auth.CustomUser and auth.ExtensionUser test models were removed

Since the introduction of migrations for the contrib apps in Django 1.8, the tables of these custom user test models were not created anymore making them unusable in a testing context.

## Apps registry is no longer auto-populated when unpickling models outside of Django

The apps registry is no longer auto-populated when unpickling models. This was added in Django 1.7.2 as an attempt to allow unpickling models outside of Django, such as in an RQ worker, without calling `django.setup()`, but it creates the possibility of a deadlock. To adapt your code in the case of RQ, you can [provide your own worker script](#) that calls `django.setup()`.

## Removed null assignment check for non-null foreign key fields

In older versions, assigning `None` to a non-nullable `ForeignKey` or `OneToOneField` raised `ValueError('Cannot assign None: "model.field" does not allow null values.')`. For consistency with other model fields which don't have a similar check, this check is removed.

## Removed weak password hashers from the default `PASSWORD_HASHERS` setting

Django 0.90 stored passwords as unsalted MD5. Django 0.91 added support for salted SHA1 with automatic upgrade of passwords when a user logs in. Django 1.4 added PBKDF2 as the default password hasher.

If you have an old Django project with MD5 or SHA1 (even salted) encoded passwords, be aware that these can be cracked fairly easily with today's hardware. To make Django users acknowledge continued use of weak hashers, the following hashers are removed from the default `PASSWORD_HASHERS` setting:

```
'django.contrib.auth.hashers.SHA1PasswordHasher'
'django.contrib.auth.hashers.MD5PasswordHasher'
'django.contrib.auth.hashers.UnsaltedSHA1PasswordHasher'
'django.contrib.auth.hashers.UnsaltedMD5PasswordHasher'
'django.contrib.auth.hashers.CryptPasswordHasher'
```

Consider using a *wrapped password hasher* to strengthen the hashes in your database. If that's not feasible, add the `PASSWORD_HASHERS` setting to your project and add back any hashers that you need.

You can check if your database has any of the removed hashers like this:

```
from django.contrib.auth import get_user_model
User = get_user_model()

# Unsalted MD5/SHA1:
User.objects.filter(password__startswith='md5$$')
User.objects.filter(password__startswith='sha1$$')
# Salted MD5/SHA1:
User.objects.filter(password__startswith='md5$').exclude(password__startswith='md5$$')
User.objects.filter(password__startswith='sha1$').exclude(password__startswith='sha1$$
↪')
# Crypt hasher:
User.objects.filter(password__startswith='crypt$$')

from django.db.models import CharField
from django.db.models.functions import Length
CharField.register_lookup(Length)
# Unsalted MD5 passwords might not have an 'md5$$' prefix:
User.objects.filter(password__length=32)
```

## `Field.get_prep_lookup()` and `Field.get_db_prep_lookup()` methods are removed

If you have a custom field that implements either of these methods, register a custom lookup for it. For example:

```
from django.db.models import Field
from django.db.models.lookups import Exact

class MyField(Field):
    ...
```

```
class MyFieldExact (Exact):
    def get_prep_lookup(self):
        # do_custom_stuff_for_myfield
        ....

MyField.register_lookup(MyFieldExact)
```

## django.contrib.gis

- Support for SpatiaLite < 3.0 and GEOS < 3.3 is dropped.
- The `add_postgis_srs()` backwards compatibility alias for `django.contrib.gis.utils.add_srs_entry()` is removed.
- On Oracle/GIS, the `Area` aggregate function now returns a `float` instead of `decimal.Decimal`. (It's still wrapped in a measure of square meters.)
- The default `GEOSGeometry` representation (WKT output) is trimmed by default. That is, instead of `POINT (23.000000000000000 5.500000000000000)`, you'll get `POINT (23 5.5)`.

## Maximum size of a request body and the number of GET/POST parameters is limited

Two new settings help mitigate denial-of-service attacks via large requests:

- `DATA_UPLOAD_MAX_MEMORY_SIZE` limits the size that a request body may be. File uploads don't count towards this limit.
- `DATA_UPLOAD_MAX_NUMBER_FIELDS` limits the number of GET/POST parameters that are parsed.

Applications that receive unusually large form posts may need to tune these settings.

## Miscellaneous

- The `repr()` of a `QuerySet` is wrapped in `<QuerySet >` to disambiguate it from a plain list when debugging.
- `utils.version.get_version()` returns **PEP 440** compliant release candidate versions (e.g. '1.10rc1' instead of '1.10c1').
- CSRF token values are now required to be strings of 64 alphanumerics; values of 32 alphanumerics, as set by older versions of Django by default, are automatically replaced by strings of 64 characters. Other values are considered invalid. This should only affect developers or users who replace these tokens.
- The `LOGOUT_URL` setting is removed as Django hasn't made use of it since pre-1.0. If you use it in your project, you can add it to your project's settings. The default value was `'/accounts/logout/'`.
- Objects with a `close()` method such as files and generators passed to `HttpResponse` are now closed immediately instead of when the WSGI server calls `close()` on the response.
- A redundant `transaction.atomic()` call in `QuerySet.update_or_create()` is removed. This may affect query counts tested by `TransactionTestCase.assertNumQueries()`.
- Support for `skip_validation` in `BaseCommand.execute(**options)` is removed. Use `skip_checks` (added in Django 1.7) instead.
- `loaddata` now raises a `CommandError` instead of showing a warning when the specified fixture file is not found.

- Instead of directly accessing the `LogEntry.change_message` attribute, it's now better to call the `LogEntry.get_change_message()` method which will provide the message in the current language.
- The default error views now raise `TemplateDoesNotExist` if a nonexistent `template_name` is specified.
- The unused `choices` keyword argument of the `Select` and `SelectMultiple` widgets' `render()` method is removed. The `choices` argument of the `render_options()` method is also removed, making `selected_choices` the first argument.
- Tests that violate deferrable database constraints will now error when run on a database that supports deferrable constraints.
- Built-in management commands now use indexing of keys in `options`, e.g. `options['verbosity']`, instead of `options.get()` and no longer perform any type coercion. This could be a problem if you're calling commands using `Command.execute()` (which bypasses the argument parser that sets a default value) instead of `call_command()`. Instead of calling `Command.execute()`, pass the command object as the first argument to `call_command()`.
- `ModelBackend` and `RemoteUserBackend` now reject inactive users. This means that inactive users can't login and will be logged out if they are switched from `is_active=True` to `False`. If you need the previous behavior, use the new `AllowAllUsersModelBackend` or `AllowAllUsersRemoteUserBackend` in `AUTHENTICATION_BACKENDS` instead.
- In light of the previous change, the test client's `login()` method no longer always rejects inactive users but instead delegates this decision to the authentication backend. `force_login()` also delegates the decision to the authentication backend, so if you're using the default backends, you need to use an active user.
- `django.views.i18n.set_language()` may now return a 204 status code for AJAX requests.
- The `base_field` attribute of `RangeField` is now a type of field, not an instance of a field. If you have created a custom subclass of `RangeField`, you should change the `base_field` attribute.
- Middleware classes are now initialized when the server starts rather than during the first request.
- If you override `is_authenticated()` or `is_anonymous()` in a custom user model, you must convert them to attributes or properties as described in [the deprecation note](#).
- When using `ModelAdmin.save_as=True`, the "Save as new" button now redirects to the change view for the new object instead of to the model's changelist. If you need the previous behavior, set the new `ModelAdmin.save_as_continue` attribute to `False`.
- Required form fields now have the `required` HTML attribute. Set the `Form.use_required_attribute` attribute to `False` to disable it. You could also add the `novalidate` attribute to `<form>` if you don't want browser validation. To disable the `required` attribute on custom widgets, override the `Widget.use_required_attribute()` method.
- The WSGI handler no longer removes content of responses from HEAD requests or responses with a `status_code` of 100-199, 204, or 304. Most Web servers already implement this behavior. Responses retrieved using the Django test client continue to have these "response fixes" applied.
- `Model.__init__()` now receives `django.db.models.DEFERRED` as the value of deferred fields.
- The `Model._deferred` attribute is removed as dynamic model classes when using `QuerySet.defer()` and `only()` is removed.
- `Storage.save()` no longer replaces `'\'` with `'/'`. This behavior is moved to `FileSystemStorage` since this is a storage specific implementation detail. Any Windows user with a custom storage implementation that relies on this behavior will need to implement it in the custom storage's `save()` method.
- Private `FileField` methods `get_directory_name()` and `get_filename()` are no longer called (and are now deprecated) which is a backwards incompatible change for users overriding those methods

on custom fields. To adapt such code, override `FileField.generate_filename()` or `Storage.generate_filename()` instead. It might be possible to use `upload_to` also.

- The subject of mail sent by `AdminEmailHandler` is no longer truncated at 989 characters. If you were counting on a limited length, truncate the subject yourself.
- Private expressions `django.db.models.expressions.Date` and `DateTime` are removed. The new `Trunc` expressions provide the same functionality.
- The `_base_manager` and `_default_manager` attributes are removed from model instances. They remain accessible on the model class.
- Accessing a deleted field on a model instance, e.g. after `del obj.field`, reloads the field's value instead of raising `AttributeError`.
- If you subclass `AbstractBaseUser` and override `clean()`, be sure it calls `super()`. `AbstractBaseUser.normalize_username()` is called in a new `AbstractBaseUser.clean()` method.
- Private API `django.forms.models.model_to_dict()` returns a queryset rather than a list of primary keys for `ManyToManyFields`.
- If `django.contrib.staticfiles` is installed, the `static` template tag uses the `staticfiles` storage to construct the URL rather than simply joining the value with `STATIC_ROOT`. The new approach encodes the URL, which could be backwards-incompatible in cases such as including a fragment in a path, e.g. `{% static 'img.svg#fragment' %}`, since the `#` is encoded as `%23`. To adapt, move the fragment outside the template tag: `{% static 'img.svg' %}#fragment`.
- When `USE_L10N` is `True`, localization is now applied for the `date` and `time` filters when no format string is specified. The `DATE_FORMAT` and `TIME_FORMAT` specifiers from the active locale are used instead of the settings of the same name.

## Features deprecated in 1.10

### Direct assignment to a reverse foreign key or many-to-many relation

Instead of assigning related objects using direct assignment:

```
>>> new_list = [obj1, obj2, obj3]
>>> e.related_set = new_list
```

Use the `set()` method added in Django 1.9:

```
>>> e.related_set.set([obj1, obj2, obj3])
```

This prevents confusion about an assignment resulting in an implicit save.

### Non-timezone-aware Storage API

The old, non-timezone-aware methods `accessed_time()`, `created_time()`, and `modified_time()` are deprecated in favor of the new `get*_time()` methods.

Third-party storage backends should implement the new methods and mark the old ones as deprecated. Until then, the new `get*_time()` methods on the base `Storage` class convert `datetimes` from the old methods as required and emit a deprecation warning as they do so.

Third-party storage backends may retain the old methods as long as they wish to support earlier versions of Django.

## django.contrib.gis

- The `get_srid()` and `set_srid()` methods of `GEOSGeometry` are deprecated in favor of the `srid` property.
- The `get_x()`, `set_x()`, `get_y()`, `set_y()`, `get_z()`, and `set_z()` methods of `Point` are deprecated in favor of the `x`, `y`, and `z` properties.
- The `get_coords()` and `set_coords()` methods of `Point` are deprecated in favor of the `tuple` property.
- The `cascaded_union` property of `MultiPolygon` is deprecated in favor of the `unary_union` property.
- The `django.contrib.gis.utils.precision_wkt()` function is deprecated in favor of `WKTWriter`.

## CommaSeparatedIntegerField model field

`CommaSeparatedIntegerField` is deprecated in favor of `CharField` with the `validate_comma_separated_integer_list()` validator:

```
from django.core.validators import validate_comma_separated_integer_list
from django.db import models

class MyModel(models.Model):
    numbers = models.CharField(..., validators=[validate_comma_separated_integer_
↪list])
```

If you're using Oracle, `CharField` uses a different database field type (`NVARCHAR2`) than `CommaSeparatedIntegerField` (`VARCHAR2`). Depending on your database settings, this might imply a different encoding, and thus a different length (in bytes) for the same contents. If your stored values are longer than the 4000 byte limit of `NVARCHAR2`, you should use `TextField` (`NCLOB`) instead. In this case, if you have any queries that group by the field (e.g. annotating the model with an aggregation or using `distinct()`) you'll need to change them (to defer the field).

## Using a model name as a query lookup when `default_related_name` is set

Assume the following models:

```
from django.db import models

class Foo(models.Model):
    pass

class Bar(models.Model):
    foo = models.ForeignKey(Foo)

    class Meta:
        default_related_name = 'bars'
```

In older versions, `default_related_name` couldn't be used as a query lookup. This is fixed and support for the old lookup name is deprecated. For example, since `default_related_name` is set in model `Bar`, instead of using the model name `bar` as the lookup:

```
>>> bar = Bar.objects.get(pk=1)
>>> Foo.objects.get(bar=bar)
```

use the `default_related_name` bars:

```
>>> Foo.objects.get(bars=bar)
```

## `__search` query lookup

The search lookup, which supports MySQL only and is extremely limited in features, is deprecated. Replace it with a custom lookup:

```
from django.db import models

class Search(models.Lookup):
    lookup_name = 'search'

    def as_mysql(self, compiler, connection):
        lhs, lhs_params = self.process_lhs(compiler, connection)
        rhs, rhs_params = self.process_rhs(compiler, connection)
        params = lhs_params + rhs_params
        return 'MATCH (%s) AGAINST (%s IN BOOLEAN MODE)' % (lhs, rhs), params

models.CharField.register_lookup(Search)
models.TextField.register_lookup(Search)
```

## Using `User.is_authenticated()` and `User.is_anonymous()` as methods

The `is_authenticated()` and `is_anonymous()` methods of `AbstractBaseUser` and `AnonymousUser` classes are now properties. They will still work as methods until Django 2.0, but all usage in Django now uses attribute access.

For example, if you use `AuthenticationMiddleware` and want to know whether the user is currently logged-in you would use:

```
if request.user.is_authenticated:
    ... # Do something for logged-in users.
else:
    ... # Do something for anonymous users.
```

instead of `request.user.is_authenticated()`.

This change avoids accidental information leakage if you forget to call the method, e.g.:

```
if request.user.is_authenticated:
    return sensitive_information
```

If you override these methods in a custom user model, you must change them to properties or attributes.

Django uses a `CallableBool` object to allow these attributes to work as both a property and a method. Thus, until the deprecation period ends, you cannot compare these properties using the `is` operator. That is, the following won't work:

```
if request.user.is_authenticated is True:
    ...
```

## Custom manager classes available through `prefetch_related` must define a `_apply_rel_filters()` method

If you defined a custom manager class available through `prefetch_related()` you must make sure it defines a `_apply_rel_filters()` method.

This method must accept a `QuerySet` instance as its single argument and return a filtered version of the queryset for the model instance the manager is bound to.

## The “escape” half of `django.utils.safestring`

The `mark_for_escaping()` function and the classes it uses: `EscapeData`, `EscapeBytes`, `EscapeText`, `EscapeString`, and `EscapeUnicode` are deprecated.

As a result, the “lazy” behavior of the escape filter (where it would always be applied as the last filter no matter where in the filter chain it appeared) is deprecated. The filter will change to immediately apply `conditional_escape()` in Django 2.0.

## `Manager.use_for_related_fields` and inheritance changes

`Manager.use_for_related_fields` is deprecated in favor of setting `Meta.base_manager_name` on the model.

Model Manager inheritance will follow MRO inheritance rules in Django 2.0, changing the current behavior where managers defined on non-abstract base classes aren’t inherited by child classes. A deprecating warning with instructions on how to adapt your code is raised if you have any affected managers. You’ll either redeclare a manager from an abstract model on the child class to override the manager from the concrete model, or you’ll set the model’s `Meta.manager_inheritance_from_future=True` option to opt-in to the new inheritance behavior.

During the deprecation period, `use_for_related_fields` will be honored and raise a warning, even if a `base_manager_name` is set. This allows third-party code to preserve legacy behavior while transitioning to the new API. The warning can be silenced by setting `silence_use_for_related_fields_deprecation=True` on the manager.

## Miscellaneous

- The `makemigrations --exit` option is deprecated in favor of the `makemigrations --check` option.
- `django.utils.functional.allow_lazy()` is deprecated in favor of the new `keep_lazy()` function which can be used with a more natural decorator syntax.
- The `shell --plain` option is deprecated in favor of `-i python` or `--interface python`.
- Importing from the `django.core.urlresolvers` module is deprecated in favor of its new location, `django.urls`.
- The template `Context.has_key()` method is deprecated in favor of `in`.
- The private attribute `virtual_fields` of `Model._meta` is deprecated in favor of `private_fields`.
- The private keyword arguments `virtual_only` in `Field.contribute_to_class()` and `virtual` in `Model._meta.add_field()` are deprecated in favor of `private_only` and `private`, respectively.
- The `javascript_catalog()` and `json_catalog()` views are deprecated in favor of class-based views `JavaScriptCatalog` and `JSONCatalog`.

- In multi-table inheritance, implicit promotion of a `OneToOneField` to a `parent_link` is deprecated. Add `parent_link=True` to such fields.
- The private API `Widget.__format_value()` is made public and renamed to `format_value()`. The old name will work through a deprecation period.
- Private `FileField` methods `get_directory_name()` and `get_filename()` are deprecated in favor of performing this work in `Storage.generate_filename()`.
- Old-style middleware that uses `settings.MIDDLEWARE_CLASSES` are deprecated. *Adapt old, custom middleware* and use the new `MIDDLEWARE` setting.

## Features removed in 1.10

These features have reached the end of their deprecation cycle and are removed in Django 1.10. See *Features deprecated in 1.8* for details, including how to remove usage of these features.

- Support for calling a `SQLCompiler` directly as an alias for calling its `quote_name_unless_alias` method is removed.
- The `cycle` and `firstof` template tags are removed from the `future` template tag library.
- `django.conf.urls.patterns()` is removed.
- Support for the `prefix` argument to `django.conf.urls.i18n.i18n_patterns()` is removed.
- `SimpleTestCase.urls` is removed.
- Using an incorrect count of unpacked values in the `for` template tag raises an exception rather than failing silently.
- The ability to *reverse()* URLs using a dotted Python path is removed.
- The ability to use a dotted Python path for the `LOGIN_URL` and `LOGIN_REDIRECT_URL` settings is removed.
- Support for `optparse` is dropped for custom management commands.
- The class `django.core.management.NoArgsCommand` is removed.
- `django.core.context_processors` module is removed.
- `django.db.models.sql.aggregates` module is removed.
- `django.contrib.gis.db.models.sql.aggregates` module is removed.
- The following methods and properties of `django.db.sql.query.Query` are removed:
  - Properties: `aggregates` and `aggregate_select`
  - Methods: `add_aggregate`, `set_aggregate_mask`, and `append_aggregate_mask`.
- `django.template.resolve_variable` is removed.
- The following private APIs are removed from `django.db.models.options.Options` (`Model._meta`):
  - `get_field_by_name()`
  - `get_all_field_names()`
  - `get_fields_with_model()`
  - `get_concrete_fields_with_model()`
  - `get_m2m_with_model()`

- `get_all_related_objects()`
- `get_all_related_objects_with_model()`
- `get_all_related_many_to_many_objects()`
- `get_all_related_m2m_objects_with_model()`
- The `error_message` argument of `django.forms.RegexField` is removed.
- The `unordered_list` filter no longer supports old style lists.
- Support for string view arguments to `url()` is removed.
- The backward compatible shim to rename `django.forms.Form._has_changed()` to `has_changed()` is removed.
- The `removetags` template filter is removed.
- The `remove_tags()` and `strip_entities()` functions in `django.utils.html` is removed.
- The `is_admin_site` argument to `django.contrib.auth.views.password_reset()` is removed.
- `django.db.models.field.subclassing.SubfieldBase` is removed.
- `django.utils.checksums` is removed.
- The `original_content_type_id` attribute on `django.contrib.admin.helpers.InlineAdminForm` is removed.
- The backwards compatibility shim to allow `FormMixin.get_form()` to be defined with no default value for its `form_class` argument is removed.
- The following settings are removed, and *you must upgrade* to the `TEMPLATES` setting:
  - `ALLOWED_INCLUDE_ROOTS`
  - `TEMPLATE_CONTEXT_PROCESSORS`
  - `TEMPLATE_DEBUG`
  - `TEMPLATE_DIRS`
  - `TEMPLATE_LOADERS`
  - `TEMPLATE_STRING_IF_INVALID`
- The backwards compatibility alias `django.template.loader.BaseLoader` is removed.
- Django template objects returned by `get_template()` and `select_template()` no longer accept a `Context` in their `render()` method.
- *Template response APIs* enforce the use of `dict` and backend-dependent template objects instead of `Context` and `Template` respectively.
- The `current_app` parameter for the following function and classes is removed:
  - `django.shortcuts.render()`
  - `django.template.Context()`
  - `django.template.RequestContext()`
  - `django.template.response.TemplateResponse()`
- The dictionary and `context_instance` parameters for the following functions are removed:
  - `django.shortcuts.render()`

- `django.shortcuts.render_to_response()`
- `django.template.loader.render_to_string()`
- The `dirs` parameter for the following functions is removed:
  - `django.template.loader.get_template()`
  - `django.template.loader.select_template()`
  - `django.shortcuts.render()`
  - `django.shortcuts.render_to_response()`
- Session verification is enabled regardless of whether or not `'django.contrib.auth.middleware.SessionAuthenticationMiddleware'` is in `MIDDLEWARE_CLASSES`. `SessionAuthenticationMiddleware` no longer has any purpose and can be removed from `MIDDLEWARE_CLASSES`. It's kept as a stub until Django 2.0 as a courtesy for users who don't read this note.
- Private attribute `django.db.models.Field.related` is removed.
- The `--list` option of the `migrate` management command is removed.
- The `ssi` template tag is removed.
- Support for the `=` comparison operator in the `if` template tag is removed.
- The backwards compatibility shims to allow `Storage.get_available_name()` and `Storage.save()` to be defined without a `max_length` argument are removed.
- Support for the legacy `% (<foo>)s` syntax in `ModelFormMixin.success_url` is removed.
- `GeoQuerySet` aggregate methods `collect()`, `extent()`, `extent3d()`, `make_line()`, and `unionagg()` are removed.
- The ability to specify `ContentType.name` when creating a content type instance is removed.
- Support for the old signature of `allow_migrate` is removed.
- Support for the syntax of `{% cycle %}` that uses comma-separated arguments is removed.
- The warning that *Signer* issued when given an invalid separator is now a `ValueError`.

## 9.1.2 1.9 release

### Django 1.9.13 release notes

April 4, 2017

Django 1.9.13 fixes two security issues and a bug in 1.9.12. This is the final release of the 1.9.x series.

#### **CVE-2017-7233: Open redirect and possible XSS attack via user-supplied numeric redirect URLs**

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()` and `il8n`) to redirect the user to an “on success” URL. The security check for these redirects (namely `django.utils.http.is_safe_url()`) considered some numeric URLs (e.g. `http:999999999`) “safe” when they shouldn't be.

Also, if a developer relies on `is_safe_url()` to provide safe redirect targets and puts such a URL into a link, they could suffer from an XSS attack.

### CVE-2017-7234: Open redirect vulnerability in `django.views.static.serve()`

A maliciously crafted URL to a Django site using the `serve()` view could redirect to any other domain. The view no longer does any redirects as they don't provide any known, useful functionality.

Note, however, that this view has always carried a warning that it is not hardened for production use and should be used only as a development aid.

### Bugfixes

- Fixed a regression in the `timesince` and `timeuntil` filters that caused incorrect results for dates in a leap year (#27637).

### Django 1.9.12 release notes

*December 1, 2016*

Django 1.9.12 fixes a regression in 1.9.11.

### Bugfixes

- Quoted the Oracle test user's password in queries to fix the "ORA-00922: missing or invalid option" error when the password starts with a number or special character (#27420).

### Django 1.9.11 release notes

*November 1, 2016*

Django 1.9.11 fixes two security issues in 1.9.10.

### User with hardcoded password created when running tests on Oracle

When running tests with an Oracle database, Django creates a temporary database user. In older versions, if a password isn't manually specified in the database settings `TEST` dictionary, a hardcoded password is used. This could allow an attacker with network access to the database server to connect.

This user is usually dropped after the test suite completes, but not when using the `manage.py test --keepdb` option or if the user has an active session (such as an attacker's connection).

A randomly generated password is now used for each test run.

### DNS rebinding vulnerability when `DEBUG=True`

Older versions of Django don't validate the `Host` header against `settings.ALLOWED_HOSTS` when `settings.DEBUG=True`. This makes them vulnerable to a [DNS rebinding attack](#).

While Django doesn't ship a module that allows remote code execution, this is at least a cross-site scripting vector, which could be quite serious if developers load a copy of the production database in development or connect to some production services for which there's no development instance, for example. If a project uses a package like the `django-debug-toolbar`, then the attacker could execute arbitrary SQL, which could be especially bad if the developers connect to the database with a superuser account.

`settings.ALLOWED_HOSTS` is now validated regardless of `DEBUG`. For convenience, if `ALLOWED_HOSTS` is empty and `DEBUG=True`, the following variations of `localhost` are allowed `['localhost', '127.0.0.1', '::1']`. If your local settings file has your production `ALLOWED_HOSTS` value, you must now omit it to get those fallback values.

## Django 1.9.10 release notes

*September 26, 2016*

Django 1.9.10 fixes a security issue in 1.9.9.

### CSRF protection bypass on a site with Google Analytics

An interaction between Google Analytics and Django’s cookie parsing could allow an attacker to set arbitrary cookies leading to a bypass of CSRF protection.

The parser for `request.COOKIES` is simplified to better match the behavior of browsers and to mitigate this attack. `request.COOKIES` may now contain cookies that are invalid according to [RFC 6265](#) but are possible to set via `document.cookie`.

## Django 1.9.9 release notes

*August 1, 2016*

Django 1.9.9 fixes several bugs in 1.9.8.

### Bugfixes

- Fixed invalid HTML in template postmortem on the debug page (#26938).
- Fixed some GIS database function crashes on MySQL 5.7 (#26657).

## Django 1.9.8 release notes

*July 18, 2016*

Django 1.9.8 fixes a security issue and several bugs in 1.9.7.

### XSS in admin’s add/change related popup

Unsafe usage of JavaScript’s `Element.innerHTML` could result in XSS in the admin’s add/change related popup. `Element.textContent` is now used to prevent execution of the data.

The debug view also used `innerHTML`. Although a security issue wasn’t identified there, out of an abundance of caution it’s also updated to use `textContent`.

### Bugfixes

- Fixed missing `varchar/text_pattern_ops` index on `CharField` and `TextField` respectively when using `AddField` on PostgreSQL (#26889).
- Fixed `makemessages` crash on Python 2 with non-ASCII file names (#26897).

## Django 1.9.7 release notes

*June 4, 2016*

Django 1.9.7 fixes several bugs in 1.9.6.

### Bugfixes

- Removed the need for the `request` context processor on the admin login page to fix a regression in 1.9 (#26558).
- Fixed translation of password validators' `help_text` in forms (#26544).
- Fixed a regression causing the cached template loader to crash when using lazy template names (#26603).
- Fixed `on_commit` callbacks execution order when callbacks make transactions (#26627).
- Fixed `HStoreField` to raise a `ValidationError` instead of crashing on non-dictionary JSON input (#26672).
- Fixed `dbshell` crash on PostgreSQL with an empty database name (#26698).
- Fixed a regression in queries on a `OneToOneField` that has `to_field` and `primary_key=True` (#26667).

## Django 1.9.6 release notes

*May 2, 2016*

Django 1.9.6 fixes several bugs in 1.9.5.

### Bugfixes

- Added support for relative path redirects to the test client and to `SimpleTestCase.assertRedirects()` because Django 1.9 no longer converts redirects to absolute URIs (#26428).
- Fixed `TimeField` microseconds round-tripping on MySQL and SQLite (#26498).
- Prevented `makemigrations` from generating infinite migrations for a model field that references a `functools.partial` (#26475).
- Fixed a regression where `SessionBase.pop()` returned `None` rather than raising a `KeyError` for non-existent values (#26520).
- Fixed a regression causing the cached template loader to crash when using template names starting with a dash (#26536).
- Restored conversion of an empty string to null when saving values of `GenericIPAddressField` on SQLite and MySQL (#26557).
- Fixed a `makemessages` regression where temporary `.py` extensions were leaked in source file paths (#26341).

## Django 1.9.5 release notes

*April 1, 2016*

Django 1.9.5 fixes several bugs in 1.9.4.

## Bugfixes

- Made `MultiPartParser` ignore filenames that normalize to an empty string to fix crash in `MemoryFileUploadHandler` on specially crafted user input (#26325).
- Fixed a race condition in `BaseCache.get_or_set()` (#26332). It now returns the default value instead of `False` if there's an error when trying to add the value to the cache.
- Fixed data loss on SQLite where `DurationField` values with fractional seconds could be saved as `None` (#26324).
- The forms in `contrib.auth` no longer strip trailing and leading whitespace from the password fields (#26334). The change requires users who set their password to something with such whitespace after a site updated to Django 1.9 to reset their password. It provides backwards-compatibility for earlier versions of Django.
- Fixed a memory leak in the cached template loader (#26306).
- Fixed a regression that caused `collectstatic --clear` to fail if the storage doesn't implement `path()` (#26297).
- Fixed a crash when using a reverse lookup with a subquery when a `ForeignKey` has a `to_field` set to something other than the primary key (#26373).
- Fixed a regression in `CommonMiddleware` that caused spurious warnings in logs on requests missing a trailing slash (#26293).
- Restored the functionality of the admin's `raw_id_fields` in `list_editable` (#26387).
- Fixed a regression with abstract model inheritance and explicit parent links (#26413).
- Fixed a migrations crash on SQLite when renaming the primary key of a model containing a `ForeignKey` to `'self'` (#26384).
- Fixed `JSONField` inadvertently escaping its contents when displaying values after failed form validation (#25532).

## Django 1.9.4 release notes

March 5, 2016

Django 1.9.4 fixes a regression on Python 2 in the 1.9.3 security release where `utils.http.is_safe_url()` crashes on bytestring URLs (#26308).

## Django 1.9.3 release notes

March 1, 2016

Django 1.9.3 fixes two security issues and several bugs in 1.9.2.

### CVE-2016-2512: Malicious redirect and possible XSS attack via user-supplied redirect URLs containing basic auth

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()` and *i18n*) to redirect the user to an “on success” URL. The security check for these redirects (namely `django.utils.http.is_safe_url()`) considered some URLs with basic authentication credentials “safe” when they shouldn't be.

For example, a URL like `http://mysite.example.com\@attacker.com` would be considered safe if the request's host is `http://mysite.example.com`, but redirecting to this URL sends the user to `attacker.com`.

Also, if a developer relies on `is_safe_url()` to provide safe redirect targets and puts such a URL into a link, they could suffer from an XSS attack.

### CVE-2016-2513: User enumeration through timing difference on password hasher work factor upgrade

In each major version of Django since 1.6, the default number of iterations for the `PBKDF2PasswordHasher` and its subclasses has increased. This improves the security of the password as the speed of hardware increases, however, it also creates a timing difference between a login request for a user with a password encoded in an older number of iterations and login request for a nonexistent user (which runs the default hasher's default number of iterations since Django 1.6).

This only affects users who haven't logged in since the iterations were increased. The first time a user logs in after an iterations increase, their password is updated with the new iterations and there is no longer a timing difference.

The new `BasePasswordHasher.harden_runtime()` method allows hashers to bridge the runtime gap between the work factor (e.g. iterations) supplied in existing encoded passwords and the default work factor of the hasher. This method is implemented for `PBKDF2PasswordHasher` and `BCryptPasswordHasher`. The number of rounds for the latter hasher hasn't changed since Django 1.4, but some projects may subclass it and increase the work factor as needed.

A warning will be emitted for any *third-party password hashers that don't implement* a `harden_runtime()` method.

If you have different password hashes in your database (such as SHA1 hashes from users who haven't logged in since the default hasher switched to PBKDF2 in Django 1.4), the timing difference on a login request for these users may be even greater and this fix doesn't remedy that difference (or any difference when changing hashers). You may be able to *upgrade those hashes* to prevent a timing attack for that case.

### Bugfixes

- Skipped URL checks (new in 1.9) if the `ROOT_URLCONF` setting isn't defined (#26155).
- Fixed a crash on PostgreSQL that prevented using `TIME_ZONE=None` and `USE_TZ=False` (#26177).
- Added system checks for query name clashes of hidden relationships (#26162).
- Fixed a regression for cases where `ForeignObject.get_extra_descriptor_filter()` returned a `Q` object (#26153).
- Fixed regression with an `__in=qs` lookup for a `ForeignKey` with `to_field` set (#26196).
- Made `forms.FileField` and `utils.translation.lazy_number()` picklable (#26212).
- Fixed `RangeField` and `ArrayField` serialization with `None` values (#26215).
- Fixed a crash when filtering by a `Decimal` in `RawQuery` (#26219).
- Reallowed dashes in top-level domain names of URLs checked by `URLValidator` to fix a regression in Django 1.8 (#26204).
- Fixed some crashing deprecation shims in `SimpleTemplateResponse` that regressed in Django 1.9 (#26253).
- Fixed `BoundField` to reallow slices of subwidgets (#26267).
- Changed the admin's "permission denied" message in the login template to use `get_username` instead of `username` to support custom user models (#26231).

- Fixed a crash when passing a nonexistent template name to the cached template loader’s `load_template()` method (#26280).
- Prevented `ContentTypeManager` instances from sharing their cache (#26286).
- Reverted a change in Django 1.9.2 (#25858) that prevented relative lazy relationships defined on abstract models to be resolved according to their concrete model’s `app_label` (#26186).

## Django 1.9.2 release notes

February 1, 2016

Django 1.9.2 fixes a security regression in 1.9 and several bugs in 1.9.1. It also makes a small backwards incompatible change that hopefully doesn’t affect any users.

### Security issue: User with “change” but not “add” permission can create objects for `ModelAdmin`’s with `save_as=True`

If a `ModelAdmin` uses `save_as=True` (not the default), the admin provides an option when editing objects to “Save as new”. A regression in Django 1.9 prevented that form submission from raising a “Permission Denied” error for users without the “add” permission.

### Backwards incompatible change: `.py-tpl` files rewritten in project/app templates

The addition of some Django template language syntax to the default app template in Django 1.9 means those files now have some invalid Python syntax. This causes difficulties for packaging systems that unconditionally byte-compile `*.py` files.

To remedy this, a `.py-tpl` suffix is now used for the project and app template files included in Django. The `.py-tpl` suffix is replaced with `.py` by the `startproject` and `startapp` commands. For example, a template with the filename `manage.py-tpl` will be created as `manage.py`.

Please file a ticket if you have a custom project template containing `.py-tpl` files and find this behavior problematic.

## Bugfixes

- Fixed a regression in `ConditionalGetMiddleware` causing `If-None-Match` checks to always return HTTP 200 (#26024).
- Fixed a regression that caused the “user-tools” items to display on the admin’s logout page (#26035).
- Fixed a crash in the translations system when the current language has no translations (#26046).
- Fixed a regression that caused the incorrect day to be selected when opening the admin calendar widget for timezones from GMT+0100 to GMT+1200 (#24980).
- Fixed a regression in the admin’s edit related model popup that caused an escaped value to be displayed in the select dropdown of the parent window (#25997).
- Fixed a regression in 1.8.8 causing incorrect index handling in migrations on PostgreSQL when adding `db_index=True` or `unique=True` to a `CharField` or `TextField` that already had the other specified, or when removing one of them from a field that had both, or when adding `unique=True` to a field already listed in `unique_together` (#26034).

- Fixed a regression where defining a relation on an abstract model's field using a string model name without an `app_label` no longer resolved that reference to the abstract model's app if using that model in another application (#25858).
- Fixed a crash when destroying an existing test database on MySQL or PostgreSQL (#26096).
- Fixed CSRF cookie check on POST requests when `USE_X_FORWARDED_PORT=True` (#26094).
- Fixed a `QuerySet.order_by()` crash when ordering by a relational field of a `ManyToManyField` through model (#26092).
- Fixed a regression that caused an exception when making database queries on SQLite with more than 2000 parameters when `DEBUG` is `True` on distributions that increase the `SQLITE_MAX_VARIABLE_NUMBER` compile-time limit to over 2000, such as Debian (#26063).
- Fixed a crash when using a reverse `OneToOneField` in `ModelAdmin.readonly_fields` (#26060).
- Fixed a crash when calling the `migrate` command in a test case with the `available_apps` attribute pointing to an application with migrations disabled using the `MIGRATION_MODULES` setting (#26135).
- Restored the ability for testing and debugging tools to determine the template from which a node came from, even during template inheritance or inclusion. Prior to Django 1.9, debugging tools could access the template origin from the node via `Node.token.source[0]`. This was an undocumented, private API. The origin is now available directly on each node using the `Node.origin` attribute (#25848).
- Fixed a regression in Django 1.8.5 that broke copying a `SimpleLazyObject` with `copy.copy()` (#26122).
- Always included `geometry_field` in the GeoJSON serializer output regardless of the `fields` parameter (#26138).
- Fixed the `contrib.gis` map widgets when using `USE_THOUSAND_SEPARATOR=True` (#20415).
- Made invalid forms display the initial of values of their disabled fields (#26129).

## Django 1.9.1 release notes

January 2, 2016

Django 1.9.1 fixes several bugs in 1.9.

### Bugfixes

- Fixed `BaseCache.get_or_set()` with the `DummyCache` backend (#25840).
- Fixed a regression in `FormMixin` causing forms to be validated twice (#25548, #26018).
- Fixed a system check crash with nested `ArrayFields` (#25867).
- Fixed a state bug when migrating a `SeparateDatabaseAndState` operation backwards (#25896).
- Fixed a regression in `CommonMiddleware` causing `If-None-Match` checks to always return HTTP 200 (#25900).
- Fixed missing `varchar/text_pattern_ops` index on `CharField` and `TextField` respectively when using `AlterField` on PostgreSQL (#25412).
- Fixed admin's delete confirmation page's summary counts of related objects (#25883).
- Added `from __future__ import unicode_literals` to the default `apps.py` created by `startapp` on Python 2 (#25909). Add this line to your own `apps.py` files created using Django 1.9 if you want your migrations to work on both Python 2 and Python 3.

- Prevented `QuerySet.delete()` from crashing on MySQL when querying across relations (#25882).
- Fixed evaluation of zero-length slices of `QuerySet.values()` (#25894).
- Fixed a state bug when using an `AlterModelManagers` operation (#25852).
- Fixed `TypedChoiceField` change detection with nullable fields (#25942).
- Fixed incorrect timezone warnings in custom admin templates that don't have a `data-admin-utc-offset` attribute in the `body` tag. (#25845).
- Fixed a regression which prevented using a language not in Django's default language list (`LANGUAGES`) (#25915).
- Avoided hiding some exceptions, like an invalid `INSTALLED_APPS` setting, behind `AppRegistryNotReady` when starting `runserver` (#25510). This regression appeared in 1.8.5 as a side effect of fixing #24704 and by mistake the fix wasn't applied to the `stable/1.9.x` branch.
- Fixed `migrate --fake-initial` detection of many-to-many tables (#25922).
- Restored the functionality of the admin's `list_editable` add and change buttons (#25903).
- Fixed `isnull` query lookup for `ForeignKey` (#25972).
- Fixed a regression in the admin which ignored line breaks in read-only fields instead of converting them to `<br>` (#25465).
- Fixed incorrect object reference in `SingleObjectMixin.get_context_object_name()` (#26006).
- Made `loaddata` skip disabling and enabling database constraints when it doesn't load any fixtures (#23372).
- Restored `contrib.auth` hashers compatibility with `py-bcrypt` (#26016).
- Fixed a crash in `QuerySet.values()/values_list()` after an `annotate()` and `order_by()` when `values()/values_list()` includes a field not in the `order_by()` (#25316).

## Django 1.9 release notes

December 1, 2015

Welcome to Django 1.9!

These release notes cover the *new features*, as well as some *backwards incompatible changes* you'll want to be aware of when upgrading from Django 1.8 or older versions. We've *dropped some features* that have reached the end of their deprecation cycle, and we've *begun the deprecation process for some features*.

See the *Upgrading Django to a newer version* guide if you're updating an existing project.

### Python compatibility

Django 1.9 requires Python 2.7, 3.4, or 3.5. We **highly recommend** and only officially support the latest release of each series.

The Django 1.8 series is the last to support Python 3.2 and 3.3.

## What's new in Django 1.9

### Performing actions after a transaction commit

The new `on_commit()` hook allows performing actions after a database transaction is successfully committed. This is useful for tasks such as sending notification emails, creating queued tasks, or invalidating caches.

This functionality from the `django-transaction-hooks` package has been integrated into Django.

### Password validation

Django now offers password validation to help prevent the usage of weak passwords by users. The validation is integrated in the included password change and reset forms and is simple to integrate in any other code. Validation is performed by one or more validators, configured in the new `AUTH_PASSWORD_VALIDATORS` setting.

Four validators are included in Django, which can enforce a minimum length, compare the password to the user's attributes like their name, ensure passwords aren't entirely numeric, or check against an included list of common passwords. You can combine multiple validators, and some validators have custom configuration options. For example, you can choose to provide a custom list of common passwords. Each validator provides a help text to explain its requirements to the user.

By default, no validation is performed and all passwords are accepted, so if you don't set `AUTH_PASSWORD_VALIDATORS`, you will not see any change. In new projects created with the default `startproject` template, a simple set of validators is enabled. To enable basic validation in the included auth forms for your project, you could set, for example:

```

AUTH_PASSWORD_VALIDATORS = [
    {
        'NAME': 'django.contrib.auth.password_validation.
↪UserAttributeSimilarityValidator',
    },
    {
        'NAME': 'django.contrib.auth.password_validation.MinimumLengthValidator',
    },
    {
        'NAME': 'django.contrib.auth.password_validation.CommonPasswordValidator',
    },
    {
        'NAME': 'django.contrib.auth.password_validation.NumericPasswordValidator',
    },
]

```

See [Password validation](#) for more details.

### Permission mixins for class-based views

Django now ships with the mixins `AccessMixin`, `LoginRequiredMixin`, `PermissionRequiredMixin`, and `UserPassesTestMixin` to provide the functionality of the `django.contrib.auth.decorators` for class-based views. These mixins have been taken from, or are at least inspired by, the `django-braces` project.

There are a few differences between Django's and `django-braces`' implementation, though:

- The `raise_exception` attribute can only be `True` or `False`. Custom exceptions or callables are not supported.

- The `handle_no_permission()` method does not take a `request` argument. The current request is available in `self.request`.
- The custom `test_func()` of `UserPassesTestMixin` does not take a `user` argument. The current user is available in `self.request.user`.
- The `permission_required` attribute supports a string (defining one permission) or a list/tuple of strings (defining multiple permissions) that need to be fulfilled to grant access.
- The new `permission_denied_message` attribute allows passing a message to the `PermissionDenied` exception.

## New styling for `contrib.admin`

The admin sports a modern, flat design with new SVG icons which look perfect on HiDPI screens. It still provides a fully-functional experience to YUI's A-grade browsers. Older browser may experience varying levels of graceful degradation.

## Running tests in parallel

The `test` command now supports a `--parallel` option to run a project's tests in multiple processes in parallel.

Each process gets its own database. You must ensure that different test cases don't access the same resources. For instance, test cases that touch the filesystem should create a temporary directory for their own use.

This option is enabled by default for Django's own test suite provided:

- the OS supports it (all but Windows)
- the database backend supports it (all the built-in backends but Oracle)

## Minor features

### `django.contrib.admin`

- Admin views now have `model_admin` or `admin_site` attributes.
- The URL of the admin change view has been changed (was at `/admin/<app>/<model>/<pk>/` by default and is now at `/admin/<app>/<model>/<pk>/change/`). This should not affect your application unless you have hardcoded admin URLs. In that case, replace those links by *reversing admin URLs* instead. Note that the old URL still redirects to the new one for backwards compatibility, but it may be removed in a future version.
- `ModelAdmin.get_list_select_related()` was added to allow changing the `select_related()` values used in the admin's changelist query based on the request.
- The `available_apps` context variable, which lists the available applications for the current user, has been added to the `AdminSite.each_context()` method.
- `AdminSite.empty_value_display` and `ModelAdmin.empty_value_display` were added to override the display of empty values in admin change list. You can also customize the value for each field.
- Added jQuery events *when an inline form is added or removed* on the change form page.
- The time picker widget includes a '6 p.m' option for consistency of having predefined options every 6 hours.
- JavaScript slug generation now supports Romanian characters.

### `django.contrib.admindocs`

- The model section of the `admindocs` now also describes methods that take arguments, rather than ignoring them.

### `django.contrib.auth`

- The default iteration count for the PBKDF2 password hasher has been increased by 20%. This backwards compatible change will not affect users who have subclassed `django.contrib.auth.hashers.PBKDF2PasswordHasher` to change the default value.
- The `BCryptSHA256PasswordHasher` will now update passwords if its `rounds` attribute is changed.
- `AbstractBaseUser` and `BaseUserManager` were moved to a new `django.contrib.auth.base_user` module so that they can be imported without including `django.contrib.auth` in `INSTALLED_APPS` (doing so raised a deprecation warning in older versions and is no longer supported in Django 1.9).
- The permission argument of `permission_required()` accepts all kinds of iterables, not only list and tuples.
- The new `PersistentRemoteUserMiddleware` makes it possible to use `REMOTE_USER` for setups where the header is only populated on login pages instead of every request in the session.
- The `password_reset()` view accepts an `extra_email_context` parameter.

### `django.contrib.contenttypes`

- It's now possible to use `order_with_respect_to` with a `GenericForeignKey`.

### `django.contrib.gis`

- All `GeoQuerySet` methods have been deprecated and replaced by *equivalent database functions*. As soon as the legacy methods have been replaced in your code, you should even be able to remove the special `GeoManager` from your GIS-enabled classes.
- The GDAL interface now supports instantiating file-based and in-memory *GDALRaster objects* from raw data. Setters for raster properties such as projection or pixel values have been added.
- For PostGIS users, the new `RasterField` allows *storing GDALRaster objects*. It supports automatic spatial index creation and reprojection when saving a model. It does not yet support spatial querying.
- The new `GDALRaster.warp()` method allows warping a raster by specifying target raster properties such as origin, width, height, or pixel size (amongst others).
- The new `GDALRaster.transform()` method allows transforming a raster into a different spatial reference system by specifying a target `srid`.
- The new `GeoIP2` class allows using MaxMind's GeoLite2 databases which includes support for IPv6 addresses.
- The default OpenLayers library version included in widgets has been updated from 2.13 to 2.13.1.

### `django.contrib.postgres`

- Added support for the `rangefield.contained_by` lookup for some built in fields which correspond to the range fields.
- Added `JSONField`.
- Added *PostgreSQL specific aggregation functions*.
- Added the `TransactionNow` database function.

### `django.contrib.sessions`

- The session model and `SessionStore` classes for the `db` and `cached_db` backends are refactored to allow a custom database session backend to build upon them. See *Extending database-backed session engines* for more details.

### `django.contrib.sites`

- `get_current_site()` now handles the case where `request.get_host()` returns `domain:port`, e.g. `example.com:80`. If the lookup fails because the host does not match a record in the database and the host has a port, the port is stripped and the lookup is retried with the domain part only.

### `django.contrib.syndication`

- Support for multiple enclosures per feed item has been added. If multiple enclosures are defined on a RSS feed, an exception is raised as RSS feeds, unlike Atom feeds, do not support multiple enclosures per feed item.

## Cache

- `django.core.cache.backends.base.BaseCache` now has a `get_or_set()` method.
- `django.views.decorators.cache.never_cache()` now sends more persuasive headers (added `no-cache`, `no-store`, `must-revalidate` to `Cache-Control`) to better prevent caching. This was also added in Django 1.8.8.

## CSRF

- The request header's name used for CSRF authentication can be customized with `CSRF_HEADER_NAME`.
- The CSRF referer header is now validated against the `CSRF_COOKIE_DOMAIN` setting if set. See *How it works* for details.
- The new `CSRF_TRUSTED_ORIGINS` setting provides a way to allow cross-origin unsafe requests (e.g. POST) over HTTPS.

## Database backends

- The PostgreSQL backend (`django.db.backends.postgresql_psycopg2`) is also available as `django.db.backends.postgresql`. The old name will continue to be available for backwards compatibility.

## File Storage

- `Storage.get_valid_name()` is now called when the `upload_to` is a callable.
- `File` now has the `seekable()` method when using Python 3.

## Forms

- `ModelForm` accepts the new Meta option `field_classes` to customize the type of the fields. See *Overriding the default fields* for details.
- You can now specify the order in which form fields are rendered with the `field_order` attribute, the `field_order` constructor argument, or the `order_fields()` method.
- A form prefix can be specified inside a form class, not only when instantiating a form. See *Prefixes for forms* for details.
- You can now *specify keyword arguments* that you want to pass to the constructor of forms in a formset.
- `SlugField` now accepts an `allow_unicode` argument to allow Unicode characters in slugs.
- `CharField` now accepts a `strip` argument to strip input data of leading and trailing whitespace. As this defaults to `True` this is different behavior from previous releases.
- Form fields now support the `disabled` argument, allowing the field widget to be displayed disabled by browsers.
- It's now possible to customize bound fields by overriding a field's `get_bound_field()` method.

## Generic Views

- Class-based views generated using `as_view()` now have `view_class` and `view_initkwargs` attributes.
- `method_decorator()` can now be used with a list or tuple of decorators. It can also be used to *decorate classes instead of methods*.

## Internationalization

- The `django.views.i18n.set_language()` view now properly redirects to *translated URLs*, when available.
- The `django.views.i18n.javascript_catalog()` view now works correctly if used multiple times with different configurations on the same page.
- The `django.utils.timezone.make_aware()` function gained an `is_dst` argument to help resolve ambiguous times during DST transitions.
- You can now use locale variants supported by gettext. These are usually used for languages which can be written in different scripts, for example Latin and Cyrillic (e.g. `be@latin`).
- Added the `django.views.i18n.json_catalog()` view to help build a custom client-side i18n library upon Django translations. It returns a JSON object containing a translations catalog, formatting settings, and a plural rule.
- Added the `name_translated` attribute to the object returned by the `get_language_info` template tag. Also added a corresponding template filter: `language_name_translated`.

- You can now run `compilemessages` from the root directory of your project and it will find all the app message files that were created by `makemessages`.
- `makemessages` now calls `xgettext` once per locale directory rather than once per translatable file. This speeds up localization builds.
- `blocktrans` supports assigning its output to a variable using `asvar`.
- Two new languages are available: Colombian Spanish and Scottish Gaelic.

## Management Commands

- The new `sendtestemail` command lets you send a test email to easily confirm that email sending through Django is working.
- To increase the readability of the SQL code generated by `sqlmigrate`, the SQL code generated for each migration operation is preceded by the operation's description.
- The `dumpdata` command output is now deterministically ordered. Moreover, when the `--output` option is specified, it also shows a progress bar in the terminal.
- The `createcachetable` command now has a `--dry-run` flag to print out the SQL rather than execute it.
- The `startapp` command creates an `apps.py` file. Since it doesn't use `default_app_config` (*a discouraged API*), you must specify the app config's path, e.g. `'polls.apps.PollsConfig'`, in `INSTALLED_APPS` for it to be used (instead of just `'polls'`).
- When using the PostgreSQL backend, the `dbshell` command can connect to the database using the password from your settings file (instead of requiring it to be manually entered).
- The `django` package may be run as a script, i.e. `python -m django`, which will behave the same as `django-admin`.
- Management commands that have the `--noinput` option now also take `--no-input` as an alias for that option.

## Migrations

- Initial migrations are now marked with an `initial = True` class attribute which allows `migrate --fake-initial` to more easily detect initial migrations.
- Added support for serialization of `functools.partial` and `LazyObject` instances.
- When supplying `None` as a value in `MIGRATION_MODULES`, Django will consider the app an app without migrations.
- When applying migrations, the “Rendering model states” step that's displayed when running `migrate` with verbosity 2 or higher now computes only the states for the migrations that have already been applied. The model states for migrations being applied are generated on demand, drastically reducing the amount of required memory.

However, this improvement is not available when unapplying migrations and therefore still requires the precomputation and storage of the intermediate migration states.

This improvement also requires that Django no longer supports mixed migration plans. Mixed plans consist of a list of migrations where some are being applied and others are being unapplied. This was never officially supported and never had a public API that supports this behavior.

- The `squashmigrations` command now supports specifying the starting migration from which migrations will be squashed.

## Models

- `QuerySet.bulk_create()` now works on proxy models.
- Database configuration gained a `TIME_ZONE` option for interacting with databases that store datetimes in local time and don't support time zones when `USE_TZ` is `True`.
- Added the `RelatedManager.set()` method to the related managers created by `ForeignKey`, `GenericForeignKey`, and `ManyToManyField`.
- The `add()` method on a reverse foreign key now has a `bulk` parameter to allow executing one query regardless of the number of objects being added rather than one query per object.
- Added the `keep_parents` parameter to `Model.delete()` to allow deleting only a child's data in a model that uses multi-table inheritance.
- `Model.delete()` and `QuerySet.delete()` return the number of objects deleted.
- Added a system check to prevent defining both `Meta.ordering` and `order_with_respect_to` on the same model.
- `Date` and `time` lookups can be chained with other lookups (such as `exact`, `gt`, `lt`, etc.). For example: `Entry.objects.filter(pub_date__month__gt=6)`.
- Time lookups (hour, minute, second) are now supported by `TimeField` for all database backends. Support for backends other than SQLite was added but undocumented in Django 1.7.
- You can specify the `output_field` parameter of the `Avg` aggregate in order to aggregate over non-numeric columns, such as `DurationField`.
- Added the `date` lookup to `DateTimeField` to allow querying the field by only the date portion.
- Added the `Greatest` and `Least` database functions.
- Added the `Now` database function, which returns the current date and time.
- `Transform` is now a subclass of `Func()` which allows `Transforms` to be used on the right hand side of an expression, just like regular `Funcs`. This allows registering some database functions like `Length`, `Lower`, and `Upper` as transforms.
- `SlugField` now accepts an `allow_unicode` argument to allow Unicode characters in slugs.
- Added support for referencing annotations in `QuerySet.distinct()`.
- `connection.queries` shows queries with substituted parameters on SQLite.
- `Query expressions` can now be used when creating new model instances using `save()`, `create()`, and `bulk_create()`.

## Requests and Responses

- Unless `HttpResponse.reason_phrase` is explicitly set, it now is determined by the current value of `HttpResponse.status_code`. Modifying the value of `status_code` outside of the constructor will also modify the value of `reason_phrase`.
- The debug view now shows details of chained exceptions on Python 3.
- The default 40x error views now accept a second positional parameter, the exception that triggered the view.
- View error handlers now support `TemplateResponse`, commonly used with class-based views.
- Exceptions raised by the `render()` method are now passed to the `process_exception()` method of each middleware.

- Request middleware can now set `HttpRequest.urlconf` to `None` to revert any changes made by previous middleware and return to using the `ROOT_URLCONF`.
- The `DISALLOWED_USER_AGENTS` check in `CommonMiddleware` now raises a `PermissionDenied` exception as opposed to returning an `HttpResponseForbidden` so that `handler403` is invoked.
- Added `HttpRequest.get_port()` to fetch the originating port of the request.
- Added the `json_dumps_params` parameter to `JsonResponse` to allow passing keyword arguments to the `json.dumps()` call used to generate the response.
- The `BrokenLinkEmailsMiddleware` now ignores 404s when the referer is equal to the requested URL. To circumvent the empty referer check already implemented, some Web bots set the referer to the requested URL.

### Templates

- Template tags created with the `simple_tag()` helper can now store results in a template variable by using the `as` argument.
- Added a `Context.setdefault()` method.
- The `django.template` logger was added and includes the following messages:
  - A DEBUG level message for missing context variables.
  - A WARNING level message for uncaught exceptions raised during the rendering of an `{% include %}` when debug mode is off (helpful since `{% include %}` silences the exception and returns an empty string).
- The `firstof` template tag supports storing the output in a variable using `'as'`.
- `Context.update()` can now be used as a context manager.
- Django template loaders can now extend templates recursively.
- The debug page template postmortem now include output from each engine that is installed.
- `Debug page integration` for custom template engines was added.
- The `DjangoTemplates` backend gained the ability to register libraries and builtins explicitly through the template `OPTIONS`.
- The `timesince` and `timeuntil` filters were improved to deal with leap years when given large time spans.
- The `include` tag now caches parsed templates objects during template rendering, speeding up reuse in places such as for loops.

### Tests

- Added the `json()` method to test client responses to give access to the response body as JSON.
- Added the `force_login()` method to the test client. Use this method to simulate the effect of a user logging into the site while skipping the authentication and verification steps of `login()`.

### URLs

- Regular expression lookaround assertions are now allowed in URL patterns.

- The application namespace can now be set using an `app_name` attribute on the included module or object. It can also be set by passing a 2-tuple of (`<list of patterns>`, `<application namespace>`) as the first argument to `include()`.
- System checks have been added for common URL pattern mistakes.

## Validators

- Added `django.core.validators.int_list_validator()` to generate validators of strings containing integers separated with a custom character.
- `EmailValidator` now limits the length of domain name labels to 63 characters per [RFC 1034](#).
- Added `validate_unicode_slug()` to validate slugs that may contain Unicode characters.

## Backwards incompatible changes in 1.9

**Warning:** In addition to the changes outlined in this section, be sure to review the [Features removed in 1.9](#) for the features that have reached the end of their deprecation cycle and therefore been removed. If you haven't updated your code within the deprecation timeline for a given feature, its removal may appear as a backwards incompatible change.

## Database backend API

- A couple of new tests rely on the ability of the backend to introspect column defaults (returning the result as `Field.default`). You can set the `can_introspect_default` database feature to `False` if your backend doesn't implement this. You may want to review the implementation on the backends that Django includes for reference ([#24245](#)).
- Registering a global adapter or converter at the level of the DB-API module to handle time zone information of `datetime` values passed as query parameters or returned as query results on databases that don't support time zones is discouraged. It can conflict with other libraries.

The recommended way to add a time zone to `datetime` values fetched from the database is to register a converter for `DateTimeField` in `DatabaseOperations.get_db_converters()`.

The `needs_datetime_string_cast` database feature was removed. Database backends that set it must register a converter instead, as explained above.

- The `DatabaseOperations.value_to_db_<type>()` methods were renamed to `adapt_<type>field_value()` to mirror the `convert_<type>field_value()` methods.
- To use the new date lookup, third-party database backends may need to implement the `DatabaseOperations.datetime_cast_date_sql()` method.
- The `DatabaseOperations.time_extract_sql()` method was added. It calls the existing `date_extract_sql()` method. This method is overridden by the SQLite backend to add time lookups (hour, minute, second) to `TimeField`, and may be needed by third-party database backends.
- The `DatabaseOperations.datetime_cast_sql()` method (not to be confused with `DatabaseOperations.datetime_cast_date_sql()` mentioned above) has been removed. This method served to format dates on Oracle long before 1.0, but hasn't been overridden by any core backend in years and hasn't been called anywhere in Django's code or tests.

- In order to support test parallelization, you must implement the `DatabaseCreation._clone_test_db()` method and set `DatabaseFeatures.can_clone_databases = True`. You may have to adjust `DatabaseCreation.get_test_db_clone_settings()`.

## Default settings that were tuples are now lists

The default settings in `django.conf.global_settings` were a combination of lists and tuples. All settings that were formerly tuples are now lists.

## `is_usable` attribute on template loaders is removed

Django template loaders previously required an `is_usable` attribute to be defined. If a loader was configured in the template settings and this attribute was `False`, the loader would be silently ignored. In practice, this was only used by the egg loader to detect if `setuptools` was installed. The `is_usable` attribute is now removed and the egg loader instead fails at runtime if `setuptools` is not installed.

## Related set direct assignment

Direct assignment of related objects in the ORM used to perform a `clear()` followed by a call to `add()`. This caused needlessly large data changes and prevented using the `m2m_changed` signal to track individual changes in many-to-many relations.

Direct assignment now relies on the the new `set()` method on related managers which by default only processes changes between the existing related set and the one that's newly assigned. The previous behavior can be restored by replacing direct assignment by a call to `set()` with the keyword argument `clear=True`.

`ModelForm`, and therefore `ModelAdmin`, internally rely on direct assignment for many-to-many relations and as a consequence now use the new behavior.

## Filesystem-based template loaders catch more specific exceptions

When using the `filesystem.Loader` or `app_directories.Loader` template loaders, earlier versions of Django raised a `TemplateDoesNotExist` error if a template source existed but was unreadable. This could happen under many circumstances, such as if Django didn't have permissions to open the file, or if the template source was a directory. Now, Django only silences the exception if the template source does not exist. All other situations result in the original `IOError` being raised.

## HTTP redirects no longer forced to absolute URIs

Relative redirects are no longer converted to absolute URIs. [RFC 2616](#) required the `Location` header in redirect responses to be an absolute URI, but it has been superseded by [RFC 7231](#) which allows relative URIs in `Location`, recognizing the actual practice of user agents, almost all of which support them.

Consequently, the expected URLs passed to `assertRedirects` should generally no longer include the scheme and domain part of the URLs. For example, `self.assertRedirects(response, 'http://testserver/some-url/')` should be replaced by `self.assertRedirects(response, '/some-url/')` (unless the redirection specifically contained an absolute URL, of course).

In the rare case that you need the old behavior (discovered with an ancient version of Apache with `mod_scgi` that interprets a relative redirect as an “internal redirect”), you can restore it by writing a custom middleware:

```
class LocationHeaderFix(object):
    def process_response(self, request, response):
        if 'Location' in response:
            response['Location'] = request.build_absolute_uri(response['Location'])
        return response
```

## Dropped support for PostgreSQL 9.0

Upstream support for PostgreSQL 9.0 ended in September 2015. As a consequence, Django 1.9 sets 9.1 as the minimum PostgreSQL version it officially supports.

## Dropped support for Oracle 11.1

Upstream support for Oracle 11.1 ended in August 2015. As a consequence, Django 1.9 sets 11.2 as the minimum Oracle version it officially supports.

## Bulk behavior of `add()` method of related managers

To improve performance, the `add()` methods of the related managers created by `ForeignKey` and `GenericForeignKey` changed from a series of `Model.save()` calls to a single `QuerySet.update()` call. The change means that `pre_save` and `post_save` signals aren't sent anymore. You can use the `bulk=False` keyword argument to revert to the previous behavior.

## Template `LoaderOrigin` and `StringOrigin` are removed

In previous versions of Django, when a template engine was initialized with `debug` as `True`, an instance of `django.template.loader.LoaderOrigin` or `django.template.base.StringOrigin` was set as the `origin` attribute on the template object. These classes have been combined into `Origin` and is now always set regardless of the engine `debug` setting. For a minimal level of backwards compatibility, the old class names will be kept as aliases to the new `Origin` class until Django 2.0.

## Changes to the default logging configuration

To make it easier to write custom logging configurations, Django's default logging configuration no longer defines `django.request` and `django.security` loggers. Instead, it defines a single `django` logger, filtered at the `INFO` level, with two handlers:

- `console`: filtered at the `INFO` level and only active if `DEBUG=True`.
- `mail_admins`: filtered at the `ERROR` level and only active if `DEBUG=False`.

If you aren't overriding Django's default logging, you should see minimal changes in behavior, but you might see some new logging to the `runserver` console, for example.

If you are overriding Django's default logging, you should check to see how your configuration merges with the new defaults.

## HttpRequest details in error reporting

It was redundant to display the full details of the `HttpRequest` each time it appeared as a stack frame variable in the HTML version of the debug page and error email. Thus, the HTTP request will now display the same standard representation as other variables (`repr(request)`). As a result, the `ExceptionReporterFilter.get_request_repr()` method and the undocumented `django.http.build_request_repr()` function were removed.

The contents of the text version of the email were modified to provide a traceback of the same structure as in the case of AJAX requests. The traceback details are rendered by the `ExceptionReporter.get_traceback_text()` method.

## Removal of time zone aware global adapters and converters for datetimes

Django no longer registers global adapters and converters for managing time zone information on `datetime` values sent to the database as query parameters or read from the database in query results. This change affects projects that meet all the following conditions:

- The `USE_TZ` setting is `True`.
- The database is SQLite, MySQL, Oracle, or a third-party database that doesn't support time zones. In doubt, you can check the value of `connection.features.supports_timezones`.
- The code queries the database outside of the ORM, typically with `cursor.execute(sql, params)`.

If you're passing aware `datetime` parameters to such queries, you should turn them into naive datetimes in UTC:

```
from django.utils import timezone
param = timezone.make_naive(param, timezone.utc)
```

If you fail to do so, the conversion will be performed as in earlier versions (with a deprecation warning) up until Django 1.11. Django 2.0 won't perform any conversion, which may result in data corruption.

If you're reading `datetime` values from the results, they will be naive instead of aware. You can compensate as follows:

```
from django.utils import timezone
value = timezone.make_aware(value, timezone.utc)
```

You don't need any of this if you're querying the database through the ORM, even if you're using `raw()` queries. The ORM takes care of managing time zone information.

## Template tag modules are imported when templates are configured

The `DjangoTemplates` backend now performs discovery on installed template tag modules when instantiated. This update enables libraries to be provided explicitly via the `'libraries'` key of `OPTIONS` when defining a `DjangoTemplates` backend. Import or syntax errors in template tag modules now fail early at instantiation time rather than when a template with a `{% load %}` tag is first compiled.

## django.template.base.add\_to\_builtins() is removed

Although it was a private API, projects commonly used `add_to_builtins()` to make template tags and filters available without using the `{% load %}` tag. This API has been formalized. Projects should now define built-in libraries via the `'builtins'` key of `OPTIONS` when defining a `DjangoTemplates` backend.

## simple\_tag now wraps tag output in conditional\_escape

In general, template tags do not autoescape their contents, and this behavior is *documented*. For tags like *inclusion\_tag*, this is not a problem because the included template will perform autoescaping. For *assignment\_tag*, the output will be escaped when it is used as a variable in the template.

For the intended use cases of *simple\_tag*, however, it is very easy to end up with incorrect HTML and possibly an XSS exploit. For example:

```
@register.simple_tag(takes_context=True)
def greeting(context):
    return "Hello {0}!".format(context['request'].user.first_name)
```

In older versions of Django, this will be an XSS issue because `user.first_name` is not escaped.

In Django 1.9, this is fixed: if the template context has `autoescape=True` set (the default), then `simple_tag` will wrap the output of the tag function with `conditional_escape()`.

To fix your `simple_tags`, it is best to apply the following practices:

- Any code that generates HTML should use either the template system or `format_html()`.
- If the output of a `simple_tag` needs escaping, use `escape()` or `conditional_escape()`.
- If you are absolutely certain that you are outputting HTML from a trusted source (e.g. a CMS field that stores HTML entered by admins), you can mark it as such using `mark_safe()`.

Tags that follow these rules will be correct and safe whether they are run on Django 1.9+ or earlier.

## Paginator.page\_range

`Paginator.page_range` is now an iterator instead of a list.

In versions of Django previous to 1.8, `Paginator.page_range` returned a `list` in Python 2 and a `range` in Python 3. Django 1.8 consistently returned a list, but an iterator is more efficient.

Existing code that depends on `list` specific features, such as indexing, can be ported by converting the iterator into a `list` using `list()`.

## Implicit queryset \_\_in lookup removed

In earlier versions, queries such as:

```
Model.objects.filter(related_id=RelatedModel.objects.all())
```

would implicitly convert to:

```
Model.objects.filter(related_id__in=RelatedModel.objects.all())
```

resulting in SQL like `"related_id IN (SELECT id FROM ...)"`.

This implicit `__in` no longer happens so the “IN” SQL is now “=”, and if the subquery returns multiple results, at least some databases will throw an error.

## contrib.admin browser support

The admin no longer supports Internet Explorer 8 and below, as these browsers have reached end-of-life.

CSS and images to support Internet Explorer 6 and 7 have been removed. PNG and GIF icons have been replaced with SVG icons, which are not supported by Internet Explorer 8 and earlier.

The jQuery library embedded in the admin has been upgraded from version 1.11.2 to 2.1.4. jQuery 2.x has the same API as jQuery 1.x, but does not support Internet Explorer 6, 7, or 8, allowing for better performance and a smaller file size. If you need to support IE8 and must also use the latest version of Django, you can override the admin's copy of jQuery with your own by creating a Django application with this structure:

```
app/static/admin/js/vendor/  
  jquery.js  
  jquery.min.js
```

## SyntaxError when installing Django setuptools 5.5.x

When installing Django 1.9 or 1.9.1 with setuptools 5.5.x, you'll see:

```
Compiling django/conf/app_template/apps.py ...  
  File "django/conf/app_template/apps.py", line 4  
    class {{ camel_case_app_name }}Config(AppConfig):  
        ^  
SyntaxError: invalid syntax  
  
Compiling django/conf/app_template/models.py ...  
  File "django/conf/app_template/models.py", line 1  
    {{ unicode_literals }}from django.db import models  
        ^  
SyntaxError: invalid syntax
```

It's safe to ignore these errors (Django will still install just fine), but you can avoid them by upgrading setuptools to a more recent version. If you're using pip, you can upgrade pip using `pip install -U pip` which will also upgrade setuptools. This is resolved in later versions of Django as described in the [Django 1.9.2 release notes](#).

## Miscellaneous

- The jQuery static files in `contrib.admin` have been moved into a `vendor/jquery` subdirectory.
- The text displayed for null columns in the admin changelist `list_display` cells has changed from `(None)` (or its translated equivalent) to `-` (a dash).
- `django.http.responses.REASON_PHRASES` and `django.core.handlers.wsgi.STATUS_CODE_TEXT` have been removed. Use Python's `stdlib` instead: `http.client.responses` for Python 3 and `httplib.responses` for Python 2.
- `ValuesQuerySet` and `ValuesListQuerySet` have been removed.
- The `admin/base.html` template no longer sets `window.__admin_media_prefix__` or `window.__admin_utc_offset__`. Image references in JavaScript that used that value to construct absolute URLs have been moved to CSS for easier customization. The UTC offset is stored on a data attribute of the `<body>` tag.
- `CommaSeparatedIntegerField` validation has been refined to forbid values like `', , ', '1',` and `'1, , 2'`.

- Form initialization was moved from the `ProcessFormView.get()` method to the new `FormMixin.get_context_data()` method. This may be backwards incompatible if you have overridden the `get_context_data()` method without calling `super()`.
- Support for PostGIS 1.5 has been dropped.
- The `django.contrib.sites.models.Site.domain` field was changed to be *unique*.
- In order to enforce test isolation, database queries are not allowed by default in `SimpleTestCase` tests anymore. You can disable this behavior by setting the `allow_database_queries` class attribute to `True` on your test class.
- `ResolverMatch.app_name` was changed to contain the full namespace path in the case of nested namespaces. For consistency with `ResolverMatch.namespace`, the empty value is now an empty string instead of `None`.
- For security hardening, session keys must be at least 8 characters.
- Private function `django.utils.functional.total_ordering()` has been removed. It contained a workaround for a `functools.total_ordering()` bug in Python versions older than 2.7.3.
- XML serialization (either through `dumpdata` or the syndication framework) used to output any characters it received. Now if the content to be serialized contains any control characters not allowed in the XML 1.0 standard, the serialization will fail with a `ValueError`.
- `CharField` now strips input of leading and trailing whitespace by default. This can be disabled by setting the new `strip` argument to `False`.
- Template text that is translated and uses two or more consecutive percent signs, e.g. `"%%"`, may have a new `msgid` after `makemessages` is run (most likely the translation will be marked fuzzy). The new `msgid` will be marked `"#, python-format"`.
- If neither `request.current_app` nor `Context.current_app` are set, the `url` template tag will now use the namespace of the current request. Set `request.current_app` to `None` if you don't want to use a namespace hint.
- The `SILENCED_SYSTEM_CHECKS` setting now silences messages of all levels. Previously, messages of `ERROR` level or higher were printed to the console.
- The `FlatPage.enable_comments` field is removed from the `FlatPageAdmin` as it's unused by the application. If your project or a third-party app makes use of it, *create a custom ModelAdmin* to add it back.
- The return value of `setup_databases()` and the first argument of `teardown_databases()` changed. They used to be `(old_names, mirrors)` tuples. Now they're just the first item, `old_names`.
- By default `LiveServerTestCase` attempts to find an available port in the 8081-8179 range instead of just trying port 8081.
- The system checks for `ModelAdmin` now check instances rather than classes.
- The private API to apply mixed migration plans has been dropped for performance reasons. Mixed plans consist of a list of migrations where some are being applied and others are being unapplied.
- The related model object descriptor classes in `django.db.models.fields.related` (private API) are moved from the `related` module to `related_descriptors` and renamed as follows:
  - `ReverseSingleRelatedObjectDescriptor` is `ForwardManyToOneDescriptor`
  - `SingleRelatedObjectDescriptor` is `ReverseOneToOneDescriptor`
  - `ForeignRelatedObjectsDescriptor` is `ReverseManyToOneDescriptor`
  - `ManyRelatedObjectsDescriptor` is `ManyToManyDescriptor`

- If you implement a custom `handler404` view, it must return a response with an HTTP 404 status code. Use `HttpResponseNotFound` or pass `status=404` to the `HttpResponse`. Otherwise, `APPEND_SLASH` won't work correctly with `DEBUG=False`.

## Features deprecated in 1.9

### `assignment_tag()`

Django 1.4 added the `assignment_tag` helper to ease the creation of template tags that store results in a template variable. The `simple_tag()` helper has gained this same ability, making the `assignment_tag` obsolete. Tags that use `assignment_tag` should be updated to use `simple_tag`.

### `{% cycle %}` syntax with comma-separated arguments

The `cycle` tag supports an inferior old syntax from previous Django versions:

```
{% cycle row1,row2,row3 %}
```

Its parsing caused bugs with the current syntax, so support for the old syntax will be removed in Django 1.10 following an accelerated deprecation.

### ForeignKey and OneToOneField on\_delete argument

In order to increase awareness about cascading model deletion, the `on_delete` argument of `ForeignKey` and `OneToOneField` will be required in Django 2.0.

Update models and existing migrations to explicitly set the argument. Since the default is `models.CASCADE`, add `on_delete=models.CASCADE` to all `ForeignKey` and `OneToOneFields` that don't use a different option. You can also pass it as the second positional argument if you don't care about compatibility with older versions of Django.

### Field.rel changes

`Field.rel` and its methods and attributes have changed to match the related fields API. The `Field.rel` attribute is renamed to `remote_field` and many of its methods and attributes are either changed or renamed.

The aim of these changes is to provide a documented API for relation fields.

### GeoManager and GeoQuerySet custom methods

All custom `GeoQuerySet` methods (`area()`, `distance()`, `gml()`, ...) have been replaced by equivalent geographic expressions in annotations (see in new features). Hence the need to set a custom `GeoManager` to GIS-enabled models is now obsolete. As soon as your code doesn't call any of the deprecated methods, you can simply remove the `objects = GeoManager()` lines from your models.

## Template loader APIs have changed

Django template loaders have been updated to allow recursive template extending. This change necessitated a new template loader API. The old `load_template()` and `load_template_sources()` methods are now deprecated. Details about the new API can be found *in the [template loader documentation](#)*.

### Passing a 3-tuple or an `app_name` to `include()`

The instance namespace part of passing a tuple as an argument to `include()` has been replaced by passing the namespace argument to `include()`. For example:

```
polls_patterns = [
    url(...),
]

urlpatterns = [
    url(r'^polls/', include((polls_patterns, 'polls', 'author-polls'))),
]
```

becomes:

```
polls_patterns = ([
    url(...),
], 'polls') # 'polls' is the app_name

urlpatterns = [
    url(r'^polls/', include(polls_patterns, namespace='author-polls')),
]
```

The `app_name` argument to `include()` has been replaced by passing a 2-tuple (as above), or passing an object or module with an `app_name` attribute (as below). If the `app_name` is set in this new way, the `namespace` argument is no longer required. It will default to the value of `app_name`. For example, the URL patterns in the tutorial are changed from:

```
mysite/urls.py

urlpatterns = [
    url(r'^polls/', include('polls.urls', namespace="polls")),
    ...
]
```

to:

```
mysite/urls.py

urlpatterns = [
    url(r'^polls/', include('polls.urls')), # 'namespace="polls"' removed
    ...
]
```

```
polls/urls.py

app_name = 'polls' # added
urlpatterns = [...]
```

This change also means that the old way of including an `AdminSite` instance is deprecated. Instead, pass `admin.site.urls` directly to `url()`:

```
urls.py
```

```
from django.conf.urls import url
from django.contrib import admin

urlpatterns = [
    url(r'^admin/', admin.site.urls),
]
```

## URL application namespace required if setting an instance namespace

In the past, an instance namespace without an application namespace would serve the same purpose as the application namespace, but it was impossible to reverse the patterns if there was an application namespace with the same name. Includes that specify an instance namespace require that the included URLconf sets an application namespace.

## current\_app parameter to contrib.auth views

All views in `django.contrib.auth.views` have the following structure:

```
def view(request, ..., current_app=None, ...):
    ...

    if current_app is not None:
        request.current_app = current_app

    return TemplateResponse(request, template_name, context)
```

As of Django 1.8, `current_app` is set on the `request` object. For consistency, these views will require the caller to set `current_app` on the request instead of passing it in a separate argument.

## django.contrib.gis.geopip

The `django.contrib.gis.geopip2` module supersedes `django.contrib.gis.geopip`. The new module provides a similar API except that it doesn't provide the legacy GeoIP-Python API compatibility methods.

## Miscellaneous

- The weak argument to `django.dispatch.signals.Signal.disconnect()` has been deprecated as it has no effect.
- The `check_aggregate_support()` method of `django.db.backends.base.BaseDatabaseOperations` has been deprecated and will be removed in Django 2.0. The more general `check_expression_support()` should be used instead.
- `django.forms.extras` is deprecated. You can find `SelectDateWidget` in `django.forms.widgets` (or simply `django.forms`) instead.
- Private API `django.db.models.fields.add_lazy_relation()` is deprecated.
- The `django.contrib.auth.tests.utils.skipIfCustomUser()` decorator is deprecated. With the test discovery changes in Django 1.6, the tests for `django.contrib` apps are no longer run as part of the user's project. Therefore, the `@skipIfCustomUser` decorator is no longer needed to decorate tests in `django.contrib.auth`.

- If you customized some *error handlers*, the view signatures with only one request parameter are deprecated. The views should now also accept a second `exception` positional parameter.
- The `django.utils.feedgenerator.Atom1Feed.mime_type` and `django.utils.feedgenerator.RssFeed.mime_type` attributes are deprecated in favor of `content_type`.
- *Signer* now issues a warning if an invalid separator is used. This will become an exception in Django 1.10.
- `django.db.models.Field._get_val_from_obj()` is deprecated in favor of `Field.value_from_object()`.
- `django.template.loaders.eggs.Loader` is deprecated as distributing applications as eggs is not recommended.
- The `callable_obj` keyword argument to `SimpleTestCase.assertRaisesMessage()` is deprecated. Pass the callable as a positional argument instead.
- The `allow_tags` attribute on methods of `ModelAdmin` has been deprecated. Use `format_html()`, `format_html_join()`, or `mark_safe()` when constructing the method's return value instead.
- The `enclosure` keyword argument to `SyndicationFeed.add_item()` is deprecated. Use the new `enclosures` argument which accepts a list of `Enclosure` objects instead of a single one.
- The `django.template.loader.LoaderOrigin` and `django.template.base.StringOrigin` aliases for `django.template.base.Origin` are deprecated.

## Features removed in 1.9

These features have reached the end of their deprecation cycle and are removed in Django 1.9. See *Features deprecated in 1.7* for details, including how to remove usage of these features.

- `django.utils.dictconfig` is removed.
- `django.utils.importlib` is removed.
- `django.utils.tzinfo` is removed.
- `django.utils.unittest` is removed.
- The `syncdb` command is removed.
- `django.db.models.signals.pre_syncdb` and `django.db.models.signals.post_syncdb` is removed.
- Support for `allow_syncdb` on database routers is removed.
- Automatic syncing of apps without migrations is removed. Migrations are compulsory for all apps unless you pass the `migrate --run-syncdb` option.
- The SQL management commands for apps without migrations, `sql`, `sqlall`, `sqlclear`, `sqldropindexes`, and `sqlindexes`, are removed.
- Support for automatic loading of `initial_data` fixtures and initial SQL data is removed.
- All models need to be defined inside an installed application or declare an explicit `app_label`. Furthermore, it isn't possible to import them before their application is loaded. In particular, it isn't possible to import models inside the root package of an application.
- The model and form `IPAddressField` is removed. A stub field remains for compatibility with historical migrations.
- `AppCommand.handle_app()` is no longer supported.

- `RequestSite` and `get_current_site()` are no longer importable from `django.contrib.sites.models`.
- FastCGI support via the `runfcgi` management command is removed.
- `django.utils.datastructures.SortedDict` is removed.
- `ModelAdmin.declared_fieldsets` is removed.
- The util modules that provided backwards compatibility are removed:
  - `django.contrib.admin.util`
  - `django.contrib.gis.db.backends.util`
  - `django.db.backends.util`
  - `django.forms.util`
- `ModelAdmin.get_formsets` is removed.
- The backward compatible shims introduced to rename the `BaseMemcachedCache.get_memcache_timeout()` method to `get_backend_timeout()` is removed.
- The `--natural` and `-n` options for `dumpdata` are removed.
- The `use_natural_keys` argument for `serializers.serialize()` is removed.
- Private API `django.forms.forms.get_declared_fields()` is removed.
- The ability to use a `SplitDateTimeWidget` with `DateTimeField` is removed.
- The `WSGIRequest.REQUEST` property is removed.
- The class `django.utils.datastructures.MergeDict` is removed.
- The `zh-cn` and `zh-tw` language codes are removed.
- The internal `django.utils.functional.memoize()` is removed.
- `django.core.cache.get_cache` is removed.
- `django.db.models.loading` is removed.
- Passing callable arguments to queriesets is no longer possible.
- `BaseCommand.requires_model_validation` is removed in favor of `requires_system_checks`. Admin validators is replaced by admin checks.
- The `ModelAdmin.validator_class` and `default_validator_class` attributes are removed.
- `ModelAdmin.validate()` is removed.
- `django.db.backends.DatabaseValidation.validate_field` is removed in favor of the `check_field` method.
- The `validate` management command is removed.
- `django.utils.module_loading.import_by_path` is removed in favor of `django.utils.module_loading.import_string`.
- `ssi` and `url` template tags are removed from the future template tag library.
- `django.utils.text.javascript_quote()` is removed.
- Database test settings as independent entries in the database settings, prefixed by `TEST_`, are no longer supported.
- The `cache_choices` option to `ModelChoiceField` and `ModelMultipleChoiceField` is removed.

- The default value of the `RedirectView.permanent` attribute has changed from `True` to `False`.
- `django.contrib.sitemaps.FlatPageSitemap` is removed in favor of `django.contrib.flatpages.sitemaps.FlatPageSitemap`.
- Private API `django.test.utils.TestTemplateLoader` is removed.
- The `django.contrib.contenttypes.generic` module is removed.

### 9.1.3 1.8 release

#### Django 1.8.18 release notes

*April 4, 2017*

Django 1.8.18 fixes two security issues in 1.8.17.

#### **CVE-2017-7233: Open redirect and possible XSS attack via user-supplied numeric redirect URLs**

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()` and `il8n`) to redirect the user to an “on success” URL. The security check for these redirects (namely `django.utils.http.is_safe_url()`) considered some numeric URLs (e.g. `http:999999999`) “safe” when they shouldn’t be.

Also, if a developer relies on `is_safe_url()` to provide safe redirect targets and puts such a URL into a link, they could suffer from an XSS attack.

#### **CVE-2017-7234: Open redirect vulnerability in `django.views.static.serve()`**

A maliciously crafted URL to a Django site using the `serve()` view could redirect to any other domain. The view no longer does any redirects as they don’t provide any known, useful functionality.

Note, however, that this view has always carried a warning that it is not hardened for production use and should be used only as a development aid.

#### Django 1.8.17 release notes

*December 1, 2016*

Django 1.8.17 fixes a regression in 1.8.16.

#### Bugfixes

- Quoted the Oracle test user’s password in queries to fix the “ORA-00922: missing or invalid option” error when the password starts with a number or special character ([#27420](#)).

#### Django 1.8.16 release notes

*November 1, 2016*

Django 1.8.16 fixes two security issues in 1.8.15.

## User with hardcoded password created when running tests on Oracle

When running tests with an Oracle database, Django creates a temporary database user. In older versions, if a password isn't manually specified in the database settings `TEST` dictionary, a hardcoded password is used. This could allow an attacker with network access to the database server to connect.

This user is usually dropped after the test suite completes, but not when using the `manage.py test --keepdb` option or if the user has an active session (such as an attacker's connection).

A randomly generated password is now used for each test run.

## DNS rebinding vulnerability when `DEBUG=True`

Older versions of Django don't validate the `Host` header against `settings.ALLOWED_HOSTS` when `settings.DEBUG=True`. This makes them vulnerable to a [DNS rebinding attack](#).

While Django doesn't ship a module that allows remote code execution, this is at least a cross-site scripting vector, which could be quite serious if developers load a copy of the production database in development or connect to some production services for which there's no development instance, for example. If a project uses a package like the `django-debug-toolbar`, then the attacker could execute arbitrary SQL, which could be especially bad if the developers connect to the database with a superuser account.

`settings.ALLOWED_HOSTS` is now validated regardless of `DEBUG`. For convenience, if `ALLOWED_HOSTS` is empty and `DEBUG=True`, the following variations of `localhost` are allowed `['localhost', '127.0.0.1', '::1']`. If your local settings file has your production `ALLOWED_HOSTS` value, you must now omit it to get those fallback values.

## Django 1.8.15 release notes

*September 26, 2016*

Django 1.8.15 fixes a security issue in 1.8.14.

## CSRF protection bypass on a site with Google Analytics

An interaction between Google Analytics and Django's cookie parsing could allow an attacker to set arbitrary cookies leading to a bypass of CSRF protection.

The parser for `request.COOKIES` is simplified to better match the behavior of browsers and to mitigate this attack. `request.COOKIES` may now contain cookies that are invalid according to [RFC 6265](#) but are possible to set via `document.cookie`.

## Django 1.8.14 release notes

*July 18, 2016*

Django 1.8.14 fixes a security issue and a bug in 1.8.13.

## XSS in admin's add/change related popup

Unsafe usage of JavaScript's `Element.innerHTML` could result in XSS in the admin's add/change related popup. `Element.textContent` is now used to prevent execution of the data.

The debug view also used `innerHTML`. Although a security issue wasn't identified there, out of an abundance of caution it's also updated to use `textContent`.

## Bugfixes

- Fixed missing `varchar/text_pattern_ops` index on `CharField` and `TextField` respectively when using `AddField` on PostgreSQL (#26889).

## Django 1.8.13 release notes

*May 2, 2016*

Django 1.8.13 fixes several bugs in 1.8.12.

## Bugfixes

- Fixed `TimeField` microseconds round-tripping on MySQL and SQLite (#26498).
- Restored conversion of an empty string to null when saving values of `GenericIPAddressField` on SQLite and MySQL (#26557).

## Django 1.8.12 release notes

*April 1, 2016*

Django 1.8.12 fixes several bugs in 1.8.11.

## Bugfixes

- Made `MultiPartParser` ignore filenames that normalize to an empty string to fix crash in `MemoryFileUploadHandler` on specially crafted user input (#26325).
- Fixed data loss on SQLite where `DurationField` values with fractional seconds could be saved as `None` (#26324).
- Restored the functionality of the admin's `raw_id_fields` in `list_editable` (#26387).

## Django 1.8.11 release notes

*March 5, 2016*

Django 1.8.11 fixes a regression on Python 2 in the 1.8.10 security release where `utils.http.is_safe_url()` crashes on bytestring URLs (#26308).

## Django 1.8.10 release notes

*March 1, 2016*

Django 1.8.10 fixes two security issues and several bugs in 1.8.9.

### CVE-2016-2512: Malicious redirect and possible XSS attack via user-supplied redirect URLs containing basic auth

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()` and `il8n`) to redirect the user to an “on success” URL. The security check for these redirects (namely `django.utils.http.is_safe_url()`) considered some URLs with basic authentication credentials “safe” when they shouldn’t be.

For example, a URL like `http://mysite.example.com\@attacker.com` would be considered safe if the request’s host is `http://mysite.example.com`, but redirecting to this URL sends the user to `attacker.com`.

Also, if a developer relies on `is_safe_url()` to provide safe redirect targets and puts such a URL into a link, they could suffer from an XSS attack.

### CVE-2016-2513: User enumeration through timing difference on password hasher work factor upgrade

In each major version of Django since 1.6, the default number of iterations for the `PBKDF2PasswordHasher` and its subclasses has increased. This improves the security of the password as the speed of hardware increases, however, it also creates a timing difference between a login request for a user with a password encoded in an older number of iterations and login request for a nonexistent user (which runs the default hasher’s default number of iterations since Django 1.6).

This only affects users who haven’t logged in since the iterations were increased. The first time a user logs in after an iterations increase, their password is updated with the new iterations and there is no longer a timing difference.

The new `BasePasswordHasher.harden_runtime()` method allows hashers to bridge the runtime gap between the work factor (e.g. iterations) supplied in existing encoded passwords and the default work factor of the hasher. This method is implemented for `PBKDF2PasswordHasher` and `BCryptPasswordHasher`. The number of rounds for the latter hasher hasn’t changed since Django 1.4, but some projects may subclass it and increase the work factor as needed.

A warning will be emitted for any *third-party password hashers that don’t implement* a `harden_runtime()` method.

If you have different password hashes in your database (such as SHA1 hashes from users who haven’t logged in since the default hasher switched to PBKDF2 in Django 1.4), the timing difference on a login request for these users may be even greater and this fix doesn’t remedy that difference (or any difference when changing hashers). You may be able to *upgrade those hashes* to prevent a timing attack for that case.

## Bugfixes

- Fixed a crash on PostgreSQL that prevented using `TIME_ZONE=None` and `USE_TZ=False` (#26177).
- Added system checks for query name clashes of hidden relationships (#26162).
- Made `forms.FileField` and `utils.translation.lazy_number()` picklable (#26212).
- Fixed `RangeField` and `ArrayField` serialization with `None` values (#26215).
- Reallowed dashes in top-level domain names of URLs checked by `URLValidator` to fix a regression in Django 1.8 (#26204).
- Fixed `BoundField` to reallow slices of subwidgets (#26267).
- Prevented `ContentTypeManager` instances from sharing their cache (#26286).

## Django 1.8.9 release notes

February 1, 2016

Django 1.8.9 fixes several bugs in 1.8.8.

### Bugfixes

- Fixed a regression that caused the “user-tools” items to display on the admin’s logout page (#26035).
- Fixed a crash in the translations system when the current language has no translations (#26046).
- Fixed a regression that caused the incorrect day to be selected when opening the admin calendar widget for timezones from GMT+0100 to GMT+1200 (#24980).
- Fixed a regression in 1.8.8 causing incorrect index handling in migrations on PostgreSQL when adding `db_index=True` or `unique=True` to a `CharField` or `TextField` that already had the other specified, or when removing one of them from a field that had both, or when adding `unique=True` to a field already listed in `unique_together` (#26034).
- Fixed a crash when using an `__in` lookup inside a `Case` expression (#26071).
- Fixed a crash when using a reverse `OneToOneField` in `ModelAdmin.readonly_fields` (#26060).
- Fixed a regression in Django 1.8.5 that broke copying a `SimpleLazyObject` with `copy.copy()` (#26122).
- Fixed the `contrib.gis` map widgets when using `USE_THOUSAND_SEPARATOR=True` (#20415).

## Django 1.8.8 release notes

January 2, 2016

Django 1.8.8 fixes several bugs in 1.8.7.

Python 3.2 users, please be advised that we’ve decided to drop support for Python 3.2 in Django 1.8.x at the end of 2016. We won’t break things intentionally after that, but we won’t test subsequent releases against Python 3.2 either. Upstream support for Python 3.2 ends February 2016 so we don’t find much value in providing security updates for a version of Python that could be insecure. To read more about the decision and to let us know if this will be problematic for you, please read the [django-developers thread](#).

### Bugfixes

- Fixed incorrect `unique_together` field name generation by `inspectdb` (#25274).
- Corrected `__len` query lookup on `ArrayField` for empty arrays (#25772).
- Restored the ability to use custom formats from `formats.py` with `django.utils.formats.get_format()` and the `date` template filter (#25812).
- Fixed a state bug when migrating a `SeparateDatabaseAndState` operation backwards (#25896).
- Fixed missing `varchar/text_pattern_ops` index on `CharField` and `TextField` respectively when using `AlterField` on PostgreSQL (#25412).
- Fixed a state bug when using an `AlterModelManagers` operation (#25852).
- Fixed a regression which prevented using a language not in Django’s default language list (`LANGUAGES`) (#25915).

- `django.views.decorators.cache.never_cache()` now sends more persuasive headers (added `no-cache`, `no-store`, `must-revalidate` to `Cache-Control`) to better prevent caching (#13008). This fixes a problem where a page refresh in Firefox cleared the selected entries in the admin's `filter_horizontal` and `filter_vertical` widgets, which could result in inadvertent data loss if a user didn't notice that and then submitted the form (#22955).
- Fixed a regression in the admin which ignored line breaks in read-only fields instead of converting them to `<br>` (#25465).
- Made `loaddata` skip disabling and enabling database constraints when it doesn't load any fixtures (#23372).
- Fixed a crash in `QuerySet.values()/values_list()` after an `annotate()` and `order_by()` when `values()/values_list()` includes a field not in the `order_by()` (#25316).

## Django 1.8.7 release notes

November 24, 2015

Django 1.8.7 fixes a security issue and several bugs in 1.8.6.

Additionally, Django's vendored version of `six`, `django.utils.six`, has been upgraded to the latest release (1.10.0).

### Fixed settings leak possibility in date template filter

If an application allows users to specify an unvalidated format for dates and passes this format to the `date` filter, e.g. `{{ last_updated|date:user_date_format }}`, then a malicious user could obtain any secret in the application's settings by specifying a settings key instead of a date format. e.g. `"SECRET_KEY"` instead of `"j/m/Y"`.

To remedy this, the underlying function used by the `date` template filter, `django.utils.formats.get_format()`, now only allows accessing the date/time formatting settings.

### Bugfixes

- Fixed a crash of the debug view during the autumn DST change when `USE_TZ` is `False` and `pytz` is installed.
- Fixed a regression in 1.8.6 that caused database routers without an `allow_migrate()` method to crash (#25686).
- Fixed a regression in 1.8.6 by restoring the ability to use `Manager` objects for the `queryset` argument of `ModelChoiceField` (#25683).
- Fixed a regression in 1.8.6 that caused an application with South migrations in the `migrations` directory to fail (#25618).
- Fixed a data loss possibility with `Prefetch` if `to_attr` is set to a `ManyToManyField` (#25693).
- Fixed a regression in 1.8 by making `gettext()` once again return UTF-8 bytestrings on Python 2 if the input is a bytestring (#25720).
- Fixed serialization of `DateRangeField` and `DateTimeRangeField` (#24937).
- Fixed the exact lookup of `ArrayField` (#25666).
- Fixed `Model.refresh_from_db()` updating of `ForeignKey` fields with `on_delete=models.SET_NULL` (#25715).
- Fixed a duplicate query regression in 1.8 on proxied model deletion (#25685).

- Fixed `set_FOO_order()` crash when the `ForeignKey` of a model with `order_with_respect_to` references a model with a `OneToOneField` primary key (#25786).
- Fixed incorrect validation for `PositiveIntegerField` and `PositiveSmallIntegerField` on MySQL resulting in values greater than 4294967295 or 65535, respectively, passing validation and being silently truncated by the database (#25767).

## Django 1.8.6 release notes

November 4, 2015

Django 1.8.6 adds official support for Python 3.5 and fixes several bugs in 1.8.5.

### Bugfixes

- Fixed a regression causing `ModelChoiceField` to ignore `prefetch_related()` on its queryset (#25496).
- Allowed “mode=memory” in SQLite test database name if supported (#12118).
- Fixed system check crash on `ForeignKey` to abstract model (#25503).
- Fixed incorrect queries when you have multiple `ManyToManyFields` on different models that have the same field name, point to the same model, and have their reverse relations disabled (#25545).
- Allowed filtering over a `RawSQL` annotation (#25506).
- Made the `Concat` database function idempotent on SQLite (#25517).
- Avoided a confusing stack trace when starting `runserver` with an invalid `INSTALLED_APPS` setting (#25510). This regression appeared in 1.8.5 as a side effect of fixing #24704.
- Made deferred models use their proxied model’s `_meta.apps` for caching and retrieval (#25563). This prevents any models generated in data migrations using `QuerySet.defer()` from leaking to test and application code.
- Fixed a typo in the name of the `strictly_above` PostGIS lookup (#25592).
- Fixed crash with `contrib.postgres.forms.SplitArrayField` and `IntegerField` on invalid value (#25597).
- Added a helpful error message when Django and South migrations exist in the same directory (#25618).
- Fixed a regression in `URLValidator` that allowed URLs with consecutive dots in the domain section (like `http://example..com/`) to pass (#25620).
- Fixed a crash with `GenericRelation` and `BaseModelAdmin.to_field_allowed` (#25622).

## Django 1.8.5 release notes

October 3, 2015

Django 1.8.5 fixes several bugs in 1.8.4.

### Bugfixes

- Made the development server’s autoreload more robust (#24704).

- Fixed `AssertionError` in some delete queries with a model containing a field that is both a foreign and primary key (#24951).
- Fixed `AssertionError` in some complex queries (#24525).
- Fixed a migrations crash with `GenericForeignKey` (#25040).
- Made `translation.override()` clear the overridden language when a translation isn't initially active (#25295).
- Fixed crash when using a value in `ModelAdmin.list_display` that clashed with a reverse field on the model (#25299).
- Fixed autocompletion for options of non-argparse management commands (#25372).
- Alphabetized ordering of imports in `from django.db import migrations, models` statement in newly created migrations (#25384).
- Fixed migrations crash on MySQL when adding a text or a blob field with an unhashable default (#25393).
- Changed `Count` queries to execute `COUNT(*)` instead of `COUNT('*)` as versions of Django before 1.8 did (#25377). This may fix a performance regression on some databases.
- Fixed custom queryset chaining with `values()` and `values_list()` (#20625).
- Moved the *unsaved model instance assignment data loss check* on reverse relations to `Model.save()` (#25160).
- Readded inline foreign keys to form instances when validating model formsets (#25431).
- Allowed using ORM write methods after disabling autocommit with `set_autocommit(False)` (#24921).
- Fixed the `manage.py test --keepdb` option on Oracle (#25421).
- Fixed incorrect queries with multiple many-to-many fields on a model with the same 'to' model and with `related_name` set to '+' (#24505, #25486).
- Fixed pickling a `SimpleLazyObject` wrapping a model (#25389).

## Django 1.8.4 release notes

August 18, 2015

Django 1.8.4 fixes a security issue and several bugs in 1.8.3.

### Denial-of-service possibility in `logout()` view by filling session store

Previously, a session could be created when anonymously accessing the `django.contrib.auth.views.logout()` view (provided it wasn't decorated with `login_required()` as done in the admin). This could allow an attacker to easily create many new session records by sending repeated requests, potentially filling up the session store or causing other users' session records to be evicted.

The `SessionMiddleware` has been modified to no longer create empty session records, including when `SESSION_SAVE_EVERY_REQUEST` is active.

### Bugfixes

- Added the ability to serialize values from the newly added `UUIDField` (#25019).

- Added a system check warning if the old `TEMPLATE_*` settings are defined in addition to the new `TEMPLATES` setting.
- Fixed `QuerySet.raw()` so `InvalidQuery` is not raised when using the `db_column` name of a `ForeignKey` field with `primary_key=True` (#12768).
- Prevented an exception in `TestCase.setUpTestData()` from leaking the transaction (#25176).
- Fixed `has_changed()` method in `contrib.postgres.forms.HStoreField` (#25215, #25233).
- Fixed the recording of squashed migrations when running the `migrate` command (#25231).
- Moved the *unsaved model instance assignment data loss check* to `Model.save()` to allow easier usage of in-memory models (#25160).
- Prevented `varchar_patterns_ops` and `text_patterns_ops` indexes for `ArrayField` (#25180).

### Django 1.8.3 release notes

July 8, 2015

Django 1.8.3 fixes several security issues and bugs in 1.8.2.

Also, `django.utils.deprecation.RemovedInDjango20Warning` was renamed to `RemovedInDjango110Warning` as the version roadmap was revised to 1.9, 1.10, 1.11 (LTS), 2.0 (drops Python 2 support). For backwards compatibility, `RemovedInDjango20Warning` remains as an importable alias.

#### Denial-of-service possibility by filling session store

In previous versions of Django, the session backends created a new empty record in the session storage anytime `request.session` was accessed and there was a session key provided in the request cookies that didn't already have a session record. This could allow an attacker to easily create many new session records simply by sending repeated requests with unknown session keys, potentially filling up the session store or causing other users' session records to be evicted.

The built-in session backends now create a session record only if the session is actually modified; empty session records are not created. Thus this potential DoS is now only possible if the site chooses to expose a session-modifying view to anonymous users.

As each built-in session backend was fixed separately (rather than a fix in the core sessions framework), maintainers of third-party session backends should check whether the same vulnerability is present in their backend and correct it if so.

#### Header injection possibility since validators accept newlines in input

Some of Django's built-in validators (*`EmailValidator`*, most seriously) didn't prohibit newline characters (due to the usage of `$` instead of `\Z` in the regular expressions). If you use values with newlines in HTTP response or email headers, you can suffer from header injection attacks. Django itself isn't vulnerable because *`HttpResponse`* and the mail sending utilities in *`django.core.mail`* prohibit newlines in HTTP and SMTP headers, respectively. While the validators have been fixed in Django, if you're creating HTTP responses or email messages in other ways, it's a good idea to ensure that those methods prohibit newlines as well. You might also want to validate that any existing data in your application doesn't contain unexpected newlines.

*`validate_ipv4_address()`*, *`validate_slug()`*, and *`URLValidator`* are also affected, however, as of Django 1.6 the *`GenericIPAddressField`*, *`IPAddressField`*, *`SlugField`*, and *`URLField`* form fields which use these validators all strip the input, so the possibility of newlines entering your data only exists if you are using these validators outside of the form fields.

The undocumented, internally unused `validate_integer()` function is now stricter as it validates using a regular expression instead of simply casting the value using `int()` and checking if an exception was raised.

## Denial-of-service possibility in URL validation

`URLValidator` included a regular expression that was extremely slow to evaluate against certain invalid inputs. This regular expression has been simplified and optimized.

## Bugfixes

- Fixed `BaseRangeField.prepare_value()` to use each `base_field`'s `prepare_value()` method (#24841).
- Fixed crash during `makemigrations` if a migrations module either is missing `__init__.py` or is a file (#24848).
- Fixed `QuerySet.exists()` returning incorrect results after annotation with `Count()` (#24835).
- Corrected `HStoreField.has_changed()` (#24844).
- Reverted an optimization to the CSRF template context processor which caused a regression (#24836).
- Fixed a regression which caused template context processors to overwrite variables set on a `RequestContext` after it's created (#24847).
- Prevented the loss of `null/not null` column properties during field renaming of MySQL databases (#24817).
- Fixed a crash when using a reverse one-to-one relation in `ModelAdmin.list_display` (#24851).
- Fixed quoting of SQL when renaming a field to `AutoField` in PostgreSQL (#24892).
- Fixed lack of unique constraint when changing a field from `primary_key=True` to `unique=True` (#24893).
- Fixed queryset pickling when using `prefetch_related()` after deleting objects (#24831).
- Allowed using `choices` longer than 1 day with `DurationField` (#24897).
- Fixed a crash when loading squashed migrations from two apps with a dependency between them, where the dependent app's replaced migrations are partially applied (#24895).
- Fixed recording of applied status for squashed (replacement) migrations (#24628).
- Fixed queryset annotations when using `Case` expressions with `exclude()` (#24833).
- Corrected join promotion for multiple `Case` expressions. Annotating a query with multiple `Case` expressions could unexpectedly filter out results (#24924).
- Fixed usage of transforms in subqueries (#24744).
- Fixed `SimpleTestCase.assertRaisesMessage()` on Python 2.7.10 (#24903).
- Provided better backwards compatibility for the `verbosity` argument in `optparse` management commands by casting it to an integer (#24769).
- Fixed `prefetch_related()` on databases other than PostgreSQL for models using UUID primary keys (#24912).
- Fixed removing `unique_together` constraints on MySQL (#24972).

- Fixed crash when uploading images with MIME types that Pillow doesn't detect, such as bitmap, in forms. `ImageField` (#24948).
- Fixed a regression when deleting a model through the admin that has a `GenericRelation` with a `related_query_name` (#24940).
- Reallowed non-ASCII values for `ForeignKey.related_name` on Python 3 by fixing the false positive system check (#25016).
- Fixed inline forms that use a parent object that has a `UUIDField` primary key and a child object that has an `AutoField` primary key (#24958).
- Fixed a regression in the `unordered_list` template filter on certain inputs (#25031).
- Fixed a regression in `URLValidator` that invalidated Punycode TLDs (#25059).
- Improved `pyinotify` runserver polling (#23882).

## Django 1.8.2 release notes

May 20, 2015

Django 1.8.2 fixes a security issue and several bugs in 1.8.1.

### Fixed session flushing in the `cached_db` backend

A change to `session.flush()` in the `cached_db` session backend in Django 1.8 mistakenly sets the session key to an empty string rather than `None`. An empty string is treated as a valid session key and the session cookie is set accordingly. Any users with an empty string in their session cookie will use the same session store. `session.flush()` is called by `django.contrib.auth.logout()` and, more seriously, by `django.contrib.auth.login()` when a user switches accounts. If a user is logged in and logs in again to a different account (without logging out) the session is flushed to avoid reuse. After the session is flushed (and its session key becomes `'`) the account details are set on the session and the session is saved. Any users with an empty string in their session cookie will now be logged into that account.

### Bugfixes

- Fixed check for template engine alias uniqueness (#24685).
- Fixed crash when reusing the same `Case` instance in a query (#24752).
- Corrected join promotion for `Case` expressions. For example, annotating a query with a `Case` expression could unexpectedly filter out results (#24766).
- Fixed negated `Q` objects in expressions. Cases like `Case(When(~Q(friends__age__lte=30)))` tried to generate a subquery which resulted in a crash (#24705).
- Fixed incorrect `GROUP BY` clause generation on MySQL when the query's model has a self-referential foreign key (#24748).
- Implemented `ForeignKey.get_db_prep_value()` so that `ForeignKeys` pointing to `UUIDField` and inheritance on models with `UUIDField` primary keys work correctly (#24698, #24712).
- Fixed `isnull` lookup for `HStoreField` (#24751).
- Fixed a MySQL crash when a migration removes a combined index (`unique_together` or `index_together`) containing a foreign key (#24757).
- Fixed session cookie deletion when using `SESSION_COOKIE_DOMAIN` (#24799).

- On PostgreSQL, when no access is granted for the `postgres` database, Django now falls back to the default database when it normally requires a “no database” connection (#24791).
- Fixed display of `contrib.admin`’s `ForeignKey` widget when it’s used in a row with other fields (#24784).

### Django 1.8.1 release notes

May 1, 2015

Django 1.8.1 fixes several bugs in 1.8 and includes some optimizations in the migrations framework.

### Bugfixes

- Added support for serializing `timedelta` objects in migrations (#24566).
- Restored proper parsing of the `testserver` command’s positional arguments (fixture names) (#24571).
- Prevented `TypeError` in translation functions `check_for_language()` and `get_language_bidi()` when translations are deactivated (#24569).
- Fixed `squashmigrations` command when using `SeparateDatabaseAndState` (#24278).
- Stripped microseconds from `datetime` values when using an older version of the MySQLdb DB API driver as it does not support fractional seconds (#24584).
- Fixed a migration crash when altering `ManyToManyFields` (#24513).
- Fixed a crash with `QuerySet.update()` on foreign keys to one-to-one fields (#24578).
- Fixed a regression in the model detail view of `admindocs` when a model has a reverse foreign key relation (#24624).
- Prevented arbitrary file inclusions in `admindocs` (#24625).
- Fixed a crash with `QuerySet.update()` on foreign keys to instances with `uuid` primary keys (#24611).
- Fixed database introspection with SQLite 3.8.9 (released April 8, 2015) (#24637).
- Updated `urlpatterns` examples generated by `startproject` to remove usage of referencing views by dotted path in `url()` which is deprecated in Django 1.8 (#24635).
- Fixed queries where an expression was referenced in `order_by()`, but wasn’t part of the select clause. An example query is `qs.annotate(foo=F('field')).values('pk').order_by('foo')` (#24615).
- Fixed a database table name quoting regression (#24605).
- Prevented the loss of `null/not null` column properties during field alteration of MySQL databases (#24595).
- Fixed JavaScript path of `contrib.admin`’s related field widget when using alternate static file storages (#24655).
- Fixed a migration crash when adding new relations to models (#24573).
- Fixed a migration crash when applying migrations with model managers on Python 3 that were generated on Python 2 (#24701).
- Restored the ability to use iterators as queryset filter arguments (#24719).
- Fixed a migration crash when renaming the target model of a many-to-many relation (#24725).
- Removed flushing of the test database with `test --keepdb`, which prevented apps with data migrations from using the option (#24729).

- Fixed `makemessages` crash in some locales (#23271).
- Fixed help text positioning of `contrib.admin` fields that use the `ModelAdmin.filter_horizontal` and `filter_vertical` options (#24676).
- Fixed `AttributeError: function 'GDALAllRegister' not found` error when initializing `contrib.gis` on Windows.

## Optimizations

- Changed `ModelState` to deepcopy fields instead of deconstructing and reconstructing (#24591). This speeds up the rendering of model states and reduces memory usage when running `manage.py migrate` (although other changes in this release may negate any performance benefits).

## Django 1.8 release notes

April 1, 2015

Welcome to Django 1.8!

These release notes cover the *new features*, as well as some *backwards incompatible changes* you'll want to be aware of when upgrading from Django 1.7 or older versions. We've also *begun the deprecation process for some features*, and some features have reached the end of their deprecation process and *have been removed*.

See the *Upgrading Django to a newer version* guide if you're updating an existing project.

Django 1.8 has been designated as Django's second *long-term support release*. It will receive security updates for at least three years after its release. Support for the previous LTS, Django 1.4, will end 6 months from the release date of Django 1.8.

## Python compatibility

Django 1.8 requires Python 2.7, 3.2, 3.3, 3.4, or 3.5. We **highly recommend** and only officially support the latest release of each series.

Django 1.8 is the first release to support Python 3.5.

Due to the end of upstream support for Python 3.2 in February 2016, we won't test Django 1.8.x on Python 3.2 after the end of 2016.

## What's new in Django 1.8

### Model.\_meta API

Django now has a formalized API for `Model._meta`, providing an officially supported way to *retrieve fields* and filter fields based on their *attributes*.

The `Model._meta` object has been part of Django since the days of pre-0.96 "Magic Removal" – it just wasn't an official, stable API. In recognition of this, we've endeavored to maintain backwards-compatibility with the old API endpoint where possible. However, API endpoints that aren't part of the new official API have been deprecated and will eventually be removed. A *guide to migrating from the old API to the new API* has been provided.

## Multiple template engines

Django 1.8 defines a stable API for integrating template backends. It includes built-in support for the Django template language and for *Jinja2*. It supports rendering templates with multiple engines within the same project. Learn more about the new features in the *topic guide* and check the *upgrade instructions* for details.

## Security enhancements

Several features of the `django-secure` third-party library have been integrated into Django. `django.middleware.security.SecurityMiddleware` provides several security enhancements to the request/response cycle. The new `check --deploy` option allows you to check your production settings file for ways to increase the security of your site.

## New PostgreSQL specific functionality

Django now has a module with extensions for PostgreSQL specific features, such as `ArrayField`, `HStoreField`, `Range Fields`, and `unaccent` lookup. A full breakdown of the features is available *in the documentation*.

## New data types

- Django now has a `UUIDField` for storing universally unique identifiers. It is stored as the native `uuid` data type on PostgreSQL and as a fixed length character field on other backends. There is a corresponding `form field`.
- Django now has a `DurationField` for storing periods of time - modeled in Python by `timedelta`. It is stored in the native `interval` data type on PostgreSQL, as a `INTERVAL DAY(9) TO SECOND(6)` on Oracle, and as a `bigint` of microseconds on other backends. Date and time related arithmetic has also been improved on all backends. There is a corresponding `form field`.

## Query Expressions, Conditional Expressions, and Database Functions

*Query Expressions* allow you to create, customize, and compose complex SQL expressions. This has enabled annotate to accept expressions other than aggregates. Aggregates are now able to reference multiple fields, as well as perform arithmetic, similar to `F()` objects. `order_by()` has also gained the ability to accept expressions.

*Conditional Expressions* allow you to use `if ... elif ... else` logic within queries.

A collection of *database functions* is also included with functionality such as `Coalesce`, `Concat`, and `Substr`.

## TestCase data setup

`TestCase` has been refactored to allow for data initialization at the class level using transactions and savepoints. Database backends which do not support transactions, like MySQL with the MyISAM storage engine, will still be able to run these tests but won't benefit from the improvements. Tests are now run within two nested `atomic()` blocks: one for the whole class and one for each test.

- The class method `TestCase.setUpTestData()` adds the ability to setup test data at the class level. Using this technique can speed up the tests as compared to using `setUp()`.
- Fixture loading within `TestCase` is now performed once for the whole `TestCase`.

## Minor features

### `django.contrib.admin`

- `ModelAdmin` now has a `has_module_permission()` method to allow limiting access to the module on the admin index page.
- `InlineModelAdmin` now has an attribute `show_change_link` that supports showing a link to an inline object's change form.
- Use the new `django.contrib.admin.RelatedOnlyFieldListFilter` in `ModelAdmin.list_filter` to limit the `list_filter` choices to foreign objects which are attached to those from the `ModelAdmin`.
- The `ModelAdmin.delete_view()` displays a summary of objects to be deleted on the deletion confirmation page.
- The jQuery library embedded in the admin has been upgraded to version 1.11.2.
- You can now specify `AdminSite.site_url` in order to display a link to the front-end site.
- You can now specify `ModelAdmin.show_full_result_count` to control whether or not the full count of objects should be displayed on a filtered admin page.
- The `AdminSite.password_change()` method now has an `extra_context` parameter.
- You can now control who may login to the admin site by overriding only `AdminSite.has_permission()` and `AdminSite.login_form`. The `base.html` template has a new block `usertools` which contains the user-specific header. A new context variable `has_permission`, which gets its value from `has_permission()`, indicates whether the user may access the site.
- Foreign key dropdowns now have buttons for changing or deleting related objects using a popup.

### `django.contrib.admindocs`

- `reStructuredText` is now parsed in model docstrings.

### `django.contrib.auth`

- Authorization backends can now raise `PermissionDenied` in `has_perm()` and `has_module_perms()` to short-circuit permission checking.
- `PasswordResetForm` now has a method `send_mail()` that can be overridden to customize the mail to be sent.
- The `max_length` of `Permission.name` has been increased from 50 to 255 characters. Please run the database migration.
- `USERNAME_FIELD` and `REQUIRED_FIELDS` now supports `ForeignKeys`.
- The default iteration count for the PBKDF2 password hasher has been increased by 33%. This backwards compatible change will not affect users who have subclassed `django.contrib.auth.hashers.PBKDF2PasswordHasher` to change the default value.

### `django.contrib.gis`

- A new *GeoJSON serializer* is now available.
- It is now allowed to include a subquery as a geographic lookup argument, for example `City.objects.filter(point__within=Country.objects.filter(continent='Africa').values('mpoly'))`.
- The SpatialLite backend now supports `Collect` and `Extent` aggregates when the database version is 3.0 or later.
- The PostGIS 2 `CREATE EXTENSION postgis` and the SpatialLite `SELECT InitSpatialMetaData` initialization commands are now automatically run by `migrate`.
- The GDAL interface now supports retrieving properties of *raster (image) data file*.
- Compatibility shims for `SpatialRefSys` and `GeometryColumns` changed in Django 1.2 have been removed.
- All GDAL-related exceptions are now raised with `GDALException`. The former `OGRException` has been kept for backwards compatibility but should not be used any longer.

### `django.contrib.sessions`

- Session cookie is now deleted after `flush()` is called.

### `django.contrib.sitemaps`

- The new `Sitemap.i18n` attribute allows you to generate a sitemap based on the `LANGUAGES` setting.

### `django.contrib.sites`

- `get_current_site()` will now lookup the current site based on `request.get_host()` if the `SITE_ID` setting is not defined.
- The default `Site` created when running `migrate` now respects the `SITE_ID` setting (instead of always using `pk=1`).

## Cache

- The `incr()` method of the `django.core.cache.backends.locmem.LocMemCache` backend is now thread-safe.

## Cryptography

- The `max_age` parameter of the `django.core.signing.TimestampSigner.unsign()` method now also accepts a `datetime.timedelta` object.

## Database backends

- The MySQL backend no longer strips microseconds from `datetime` values as MySQL 5.6.4 and up supports fractional seconds depending on the declaration of the `datetime` field (when `DATETIME` includes fractional precision greater than 0). New `datetime` database columns created with Django 1.8 and MySQL 5.6.4 and up will support microseconds. See the [MySQL database notes](#) for more details.
- The MySQL backend no longer creates explicit indexes for foreign keys when using the InnoDB storage engine, as MySQL already creates them automatically.
- The Oracle backend no longer defines the `connection_persists_old_columns` feature as `True`. Instead, Oracle will now include a cache busting clause when getting the description of a table.

## Email

- [Email backends](#) now support the context manager protocol for opening and closing connections.
- The SMTP email backend now supports `keyfile` and `certfile` authentication with the `EMAIL_SSL_CERTFILE` and `EMAIL_SSL_KEYFILE` settings.
- The SMTP [EmailBackend](#) now supports setting the `timeout` parameter with the `EMAIL_TIMEOUT` setting.
- [EmailMessage](#) and [EmailMultiAlternatives](#) now support the `reply_to` parameter.

## File Storage

- [Storage.get\\_available\\_name\(\)](#) and [Storage.save\(\)](#) now take a `max_length` argument to implement storage-level maximum filename length constraints. Filenames exceeding this argument will get truncated. This prevents a database error when appending a unique suffix to a long filename that already exists on the storage. See the [deprecation note](#) about adding this argument to your custom storage classes.

## Forms

- Form widgets now render attributes with a value of `True` or `False` as HTML5 boolean attributes.
- The new [has\\_error\(\)](#) method allows checking if a specific error has happened.
- If [required\\_css\\_class](#) is defined on a form, then the `<label>` tags for required fields will have this class present in its attributes.
- The rendering of non-field errors in unordered lists (`<ul>`) now includes `nonfield` in its list of classes to distinguish them from field-specific errors.
- [Field](#) now accepts a `label_suffix` argument, which will override the form's `label_suffix`. This enables customizing the suffix on a per-field basis — previously it wasn't possible to override a form's `label_suffix` while using shortcuts such as `{{ form.as_p }}` in templates.
- [SelectDateWidget](#) now accepts an `empty_label` argument, which will override the top list choice label when [DateField](#) is not required.
- After an [ImageField](#) has been cleaned and validated, the `UploadedFile` object will have an additional `image` attribute containing the `Pillow Image` instance used to check if the file was a valid image. It will also update `UploadedFile.content_type` with the image's content type as determined by `Pillow`.
- You can now pass a callable that returns an iterable of choices when instantiating a [ChoiceField](#).

## Generic Views

- Generic views that use *MultipleObjectMixin* may now specify the ordering applied to the *queryset* by setting *ordering* or overriding *get\_ordering()*.
- The new *SingleObjectMixin.query\_pk\_and\_slug* attribute allows changing the behavior of *get\_object()* so that it'll perform its lookup using both the primary key and the slug.
- The *get\_form()* method doesn't require a *form\_class* to be provided anymore. If not provided *form\_class* defaults to *get\_form\_class()*.
- Placeholders in *ModelFormMixin.success\_url* now support the Python *str.format()* syntax. The legacy *% (<foo>)* syntax is still supported but will be removed in Django 1.10.

## Internationalization

- *FORMAT\_MODULE\_PATH* can now be a list of strings representing module paths. This allows importing several format modules from different reusable apps. It also allows overriding those custom formats in your main Django project.

## Logging

- The *django.utils.log.AdminEmailHandler* class now has a *send\_mail()* method to make it more subclass friendly.

## Management Commands

- Database connections are now always closed after a management command called from the command line has finished doing its job.
- Commands from alternate package formats like eggs are now also discovered.
- The new *dumpdata --output* option allows specifying a file to which the serialized data is written.
- The new *makemessages --exclude* and *compilemessages --exclude* options allow excluding specific locales from processing.
- *compilemessages* now has a *--use-fuzzy* or *-f* option which includes fuzzy translations into compiled files.
- The *loaddata --ignorenonexistent* option now ignores data for models that no longer exist.
- *runserver* now uses daemon threads for faster reloading.
- *inspectdb* now outputs *Meta.unique\_together*. It is also able to introspect *AutoField* for MySQL and PostgreSQL databases.
- When calling management commands with options using *call\_command()*, the option name can match the command line option name (without the initial dashes) or the final option destination variable name, but in either case, the resulting option received by the command is now always the *dest* name specified in the command option definition (as long as the command uses the *argparse* module).
- The *dbshell* command now supports MySQL's optional SSL certificate authority setting (*--ssl-ca*).
- The new *makemigrations --name* allows giving the migration(s) a custom name instead of a generated one.

- The `loaddata` command now prevents repeated fixture loading. If `FIXTURE_DIRS` contains duplicates or a default fixture directory path (`app_name/fixtures`), an exception is raised.
- The new `makemigrations --exit` option allows exiting with an error code if no migrations are created.
- The new `showmigrations` command allows listing all migrations and their dependencies in a project.

## Middleware

- The `CommonMiddleware.response_redirect_class` attribute allows you to customize the redirects issued by the middleware.
- A debug message will be logged to the `django.request` logger when a middleware raises a `MiddlewareNotUsed` exception in `DEBUG` mode.

## Migrations

- The `RunSQL` operation can now handle parameters passed to the SQL statements.
- It is now possible to have migrations (most probably *data migrations*) for applications without models.
- Migrations can now *serialize model managers* as part of the model state.
- A *generic mechanism to handle the deprecation of model fields* was added.
- The `RunPython.noop()` and `RunSQL.noop` class method/attribute were added to ease in making `RunPython` and `RunSQL` operations reversible.
- The migration operations `RunPython` and `RunSQL` now call the `allow_migrate()` method of database routers. The router can use the newly introduced `app_label` and `hints` arguments to make a routing decision. To take advantage of this feature you need to update the router to the new `allow_migrate` signature, see the *deprecation section* for more details.

## Models

- Django now logs at most 9000 queries in `connections.queries`, in order to prevent excessive memory usage in long-running processes in debug mode.
- There is now a model `Meta` option to define a *default related name* for all relational fields of a model.
- Pickling models and querysets across different versions of Django isn't officially supported (it may work, but there's no guarantee). An extra variable that specifies the current Django version is now added to the pickled state of models and querysets, and Django raises a `RuntimeWarning` when these objects are unpickled in a different version than the one in which they were pickled.
- Added `Model.from_db()` which Django uses whenever objects are loaded using the ORM. The method allows customizing model loading behavior.
- `extra(select={...})` now allows you to escape a literal `%s` sequence using `%%s`.
- *Custom Lookups* can now be registered using a decorator pattern.
- The new `Transform.bilateral` attribute allows creating bilateral transformations. These transformations are applied to both `lhs` and `rhs` when used in a lookup expression, providing opportunities for more sophisticated lookups.

- SQL special characters (`,` `%`, `_`) are now escaped properly when a pattern lookup (e.g. `contains`, `startswith`, etc.) is used with an `F()` expression as the right-hand side. In those cases, the escaping is performed by the database, which can lead to somewhat complex queries involving nested `REPLACE` function calls.
- You can now refresh model instances by using `Model.refresh_from_db()`.
- You can now get the set of deferred fields for a model using `Model.get_deferred_fields()`.
- Model field default's are now used when primary key field's are set to `None`.

## Signals

- Exceptions from the `(receiver, exception)` tuples returned by `Signal.send_robust()` now have their traceback attached as a `__traceback__` attribute.
- The `environ` argument, which contains the WSGI environment structure from the request, was added to the `request_started` signal.
- You can now import the `setting_changed()` signal from `django.core.signals` to avoid loading `django.test` in non-test situations. Django no longer does so itself.

## System Check Framework

- `register` can now be used as a function.

## Templates

- `urlize` now supports domain-only links that include characters after the top-level domain (e.g. `djangoproject.com/` and `djangoproject.com/download/`).
- `urlize` doesn't treat exclamation marks at the end of a domain or its query string as part of the URL (the URL in e.g. `'djangoproject.com!' is djangoproject.com`)
- Added a `locmem.Loader` class that loads Django templates from a Python dictionary.
- The `now` tag can now store its output in a context variable with the usual syntax: `{% now 'j n Y' as varname %}`.

## Requests and Responses

- `WSGIRequest` now respects paths starting with `//`.
- The `HttpRequest.build_absolute_uri()` method now handles paths starting with `//` correctly.
- If `DEBUG` is `True` and a request raises a `SuspiciousOperation`, the response will be rendered with a detailed error page.
- The `query_string` argument of `QueryDict` is now optional, defaulting to `None`, so a blank `QueryDict` can now be instantiated with `QueryDict()` instead of `QueryDict(None)` or `QueryDict('')`.
- The `GET` and `POST` attributes of an `HttpRequest` object are now `QueryDicts` rather than dictionaries, and the `FILES` attribute is now a `MultiValueDict`. This brings this class into line with the documentation and with `WSGIRequest`.
- The `HttpResponse.charset` attribute was added.

- `WSGIRequestHandler` now follows RFC in converting URI to IRI, using `uri_to_iri()`.
- The `HttpRequest.get_full_path()` method now escapes unsafe characters from the path portion of a Uniform Resource Identifier (URI) properly.
- `HttpResponse` now implements a few additional methods like `getvalue()` so that instances can be used as stream objects.
- The new `HttpResponse.setdefault()` method allows setting a header unless it has already been set.
- You can use the new `FileResponse` to stream files.
- The `condition()` decorator for conditional view processing now supports the `If-unmodified-since` header.

## Tests

- The `RequestFactory.trace()` and `Client.trace()` methods were implemented, allowing you to create TRACE requests in your tests.
- The `count` argument was added to `assertTemplateUsed()`. This allows you to assert that a template was rendered a specific number of times.
- The new `assertJSONNotEqual()` assertion allows you to test that two JSON fragments are not equal.
- Added options to the `test` command to preserve the test database (`--keepdb`), to run the test cases in reverse order (`--reverse`), and to enable SQL logging for failing tests (`--debug-sql`).
- Added the `resolver_match` attribute to test client responses.
- Added several settings that allow customization of test tablespace parameters for Oracle: `DATAFILE`, `DATAFILE_TMP`, `DATAFILE_MAXSIZE` and `DATAFILE_TMP_MAXSIZE`.
- The `override_settings()` decorator can now affect the master router in `DATABASE_ROUTERS`.
- Added test client support for file uploads with file-like objects.
- A shared cache is now used when testing with an SQLite in-memory database when using Python 3.4+ and SQLite 3.7.13+. This allows sharing the database between threads.

## Validators

- `URLValidator` now supports IPv6 addresses, unicode domains, and URLs containing authentication data.

## Backwards incompatible changes in 1.8

**Warning:** In addition to the changes outlined in this section, be sure to review the [deprecation plan](#) for any features that have been removed. If you haven't updated your code within the deprecation timeline for a given feature, its removal may appear as a backwards incompatible change.

## Related object operations are run in a transaction

Some operations on related objects such as `add()` or direct assignment ran multiple data modifying queries without wrapping them in transactions. To reduce the risk of data corruption, all data modifying methods that affect multiple

related objects (i.e. `add()`, `remove()`, `clear()`, and direct assignment) now perform their data modifying queries from within a transaction, provided your database supports transactions.

This has one backwards incompatible side effect, signal handlers triggered from these methods are now executed within the method's transaction and any exception in a signal handler will prevent the whole operation.

### Assigning unsaved objects to relations raises an error

---

**Note:** To more easily allow in-memory usage of models, this change was reverted in Django 1.8.4 and replaced with a check during `model.save()`. For example:

```
>>> book = Book.objects.create(name="Django")
>>> book.author = Author(name="John")
>>> book.save()
Traceback (most recent call last):
...
ValueError: save() prohibited to prevent data loss due to unsaved related object
↳ 'author'.
```

A similar check on assignment to reverse one-to-one relations was removed in Django 1.8.5.

---

Assigning unsaved objects to a *ForeignKey*, *GenericForeignKey*, and *OneToOneField* now raises a *ValueError*.

Previously, the assignment of an unsaved object would be silently ignored. For example:

```
>>> book = Book.objects.create(name="Django")
>>> book.author = Author(name="John")
>>> book.author.save()
>>> book.save()

>>> Book.objects.get(name="Django")
>>> book.author
>>>
```

Now, an error will be raised to prevent data loss:

```
>>> book.author = Author(name="john")
Traceback (most recent call last):
...
ValueError: Cannot assign "<Author: John>": "Author" instance isn't saved in the_
↳ database.
```

If you require allowing the assignment of unsaved instances (the old behavior) and aren't concerned about the data loss possibility (e.g. you never save the objects to the database), you can disable this check by using the `ForeignKey.allow_unsaved_instance_assignment` attribute. (This attribute was removed in 1.8.4 as it's no longer relevant.)

### Management commands that only accept positional arguments

If you have written a custom management command that only accepts positional arguments and you didn't specify the `args` command variable, you might get an error like `Error: unrecognized arguments: ...`, as variable parsing is now based on `argparse` which doesn't implicitly accept positional arguments. You can make your command backwards compatible by simply setting the `args` class variable. However, if you don't have to keep

compatibility with older Django versions, it's better to implement the new `add_arguments()` method as described in *Writing custom django-admin commands*.

### Custom test management command arguments through test runner

The method to add custom arguments to the `test` management command through the test runner has changed. Previously, you could provide an `option_list` class variable on the test runner to add more arguments (à la `optparse`). Now to implement the same behavior, you have to create an `add_arguments(cls, parser)` class method on the test runner and call `parser.add_argument` to add any custom arguments, as `parser` is now an `ArgumentParser` instance.

### Model check ensures auto-generated column names are within limits specified by database

A field name that's longer than the column name length supported by a database can create problems. For example, with MySQL you'll get an exception trying to create the column, and with PostgreSQL the column name is truncated by the database (you may see a warning in the PostgreSQL logs).

A model check has been introduced to better alert users to this scenario before the actual creation of database tables.

If you have an existing model where this check seems to be a false positive, for example on PostgreSQL where the name was already being truncated, simply use `db_column` to specify the name that's being used.

The check also applies to the columns generated in an implicit `ManyToManyField.through` model. If you run into an issue there, use `through` to create an explicit model and then specify `db_column` on its column(s) as needed.

### Query relation lookups now check object types

Querying for model lookups now checks if the object passed is of correct type and raises a `ValueError` if not. Previously, Django didn't care if the object was of correct type; it just used the object's related field attribute (e.g. `id`) for the lookup. Now, an error is raised to prevent incorrect lookups:

```
>>> book = Book.objects.create(name="Django")
>>> book = Book.objects.filter(author=book)
Traceback (most recent call last):
...
ValueError: Cannot query "<Book: Django>": Must be "Author" instance.
```

### `select_related()` now checks given fields

`select_related()` now validates that the given fields actually exist. Previously, nonexistent fields were silently ignored. Now, an error is raised:

```
>>> book = Book.objects.select_related('nonexistent_field')
Traceback (most recent call last):
...
FieldError: Invalid field name(s) given in select_related: 'nonexistent_field'
```

The validation also makes sure that the given field is relational:

```
>>> book = Book.objects.select_related('name')
Traceback (most recent call last):
...
FieldError: Non-relational field given in select_related: 'name'
```

### Default `EmailField.max_length` increased to 254

The old default 75 character `max_length` was not capable of storing all possible RFC3696/5321-compliant email addresses. In order to store all possible valid email addresses, the `max_length` has been increased to 254 characters. You will need to generate and apply database migrations for your affected models (or add `max_length=75` if you wish to keep the length on your current fields). A migration for `django.contrib.auth.models.User.email` is included.

### Support for PostgreSQL versions older than 9.0

The end of upstream support periods was reached in July 2014 for PostgreSQL 8.4. As a consequence, Django 1.8 sets 9.0 as the minimum PostgreSQL version it officially supports.

This also includes dropping support for PostGIS 1.3 and 1.4 as these versions are not supported on versions of PostgreSQL later than 8.4.

Django also now requires the use of `Psycopg2` version 2.4.5 or higher (or 2.5+ if you want to use `django.contrib.postgres`).

### Support for MySQL versions older than 5.5

The end of upstream support periods was reached in January 2012 for MySQL 5.0 and December 2013 for MySQL 5.1. As a consequence, Django 1.8 sets 5.5 as the minimum MySQL version it officially supports.

### Support for Oracle versions older than 11.1

The end of upstream support periods was reached in July 2010 for Oracle 9.2, January 2012 for Oracle 10.1, and July 2013 for Oracle 10.2. As a consequence, Django 1.8 sets 11.1 as the minimum Oracle version it officially supports.

### Specific privileges used instead of roles for tests on Oracle

Earlier versions of Django granted the `CONNECT` and `RESOURCE` roles to the test user on Oracle. These roles have been deprecated, so Django 1.8 uses the specific underlying privileges instead. This changes the privileges required of the main user for running tests (unless the project is configured to avoid creating a test user). The exact privileges required now are detailed in *Oracle notes*.

### `AbstractUser.last_login` allows null values

The `AbstractUser.last_login` field now allows null values. Previously, it defaulted to the time when the user was created which was misleading if the user never logged in. If you are using the default user (`django.contrib.auth.models.User`), run the database migration included in `contrib.auth`.

If you are using a custom user model that inherits from `AbstractUser`, you'll need to run `makemigrations` and generate a migration for your app that contains that model. Also, if wish to set `last_login` to `NULL` for users who haven't logged in, you can run this query:

```
from django.db import models
from django.contrib.auth import get_user_model
from django.contrib.auth.models import AbstractBaseUser

UserModel = get_user_model()
if issubclass(UserModel, AbstractBaseUser):
    UserModel._default_manager.filter(
        last_login=models.F('date_joined')
    ).update(last_login=None)
```

### `django.contrib.gis`

- Support for GEOS 3.1 and GDAL 1.6 has been dropped.
- Support for SpatiaLite < 2.4 has been dropped.
- GIS-specific lookups have been refactored to use the `django.db.models.Lookup` API.
- The default `str` representation of `GEOSGeometry` objects has been changed from WKT to EWKT format (including the SRID). As this representation is used in the serialization framework, that means that `dumpdata` output will now contain the SRID value of geometry objects.

### Priority of context processors for `TemplateResponse` brought in line with `render`

The `TemplateResponse` constructor is designed to be a drop-in replacement for the `render()` function. However, it had a slight incompatibility, in that for `TemplateResponse`, context data from the passed in context dictionary could be shadowed by context data returned from context processors, whereas for `render` it was the other way around. This was a bug, and the behavior of `render` is more appropriate, since it allows the globally defined context processors to be overridden locally in the view. If you were relying on the fact context data in a `TemplateResponse` could be overridden using a context processor, you will need to change your code.

### Overriding `setUpClass` / `tearDownClass` in test cases

The decorators `override_settings()` and `modify_settings()` now act at the class level when used as class decorators. As a consequence, when overriding `setUpClass()` or `tearDownClass()`, the super implementation should always be called.

### Removal of `django.contrib.formtools`

The `formtools` contrib app has been moved to a separate package and the relevant documentation pages have been updated or removed.

The new package is available [on GitHub](#) and [on PyPI](#).

## Database connection reloading between tests

Django previously closed database connections between each test within a `TestCase`. This is no longer the case as Django now wraps the whole `TestCase` within a transaction. If some of your tests relied on the old behavior, you should have them inherit from `TransactionTestCase` instead.

## Cleanup of the `django.template` namespace

If you've been relying on private APIs exposed in the `django.template` module, you may have to import them from `django.template.base` instead.

Also private APIs `django.template.base.compile_string()`, `django.template.loader.find_template()`, and `django.template.loader.get_template_from_string()` were removed.

## `model` attribute on private model relations

In earlier versions of Django, on a model with a reverse foreign key relationship (for example), `model._meta.get_all_related_objects()` returned the relationship as a `django.db.models.related.RelatedObject` with the `model` attribute set to the source of the relationship. Now, this method returns the relationship as `django.db.models.fields.related.ManyToOneRel` (private API `RelatedObject` has been removed), and the `model` attribute is set to the target of the relationship instead of the source. The source model is accessible on the `related_model` attribute instead.

Consider this example from the tutorial in Django 1.8:

```
>>> p = Poll.objects.get(pk=1)
>>> p._meta.get_all_related_objects()
[<ManyToOneRel: polls.choice>]
>>> p._meta.get_all_related_objects()[0].model
<class 'polls.models.Poll'>
>>> p._meta.get_all_related_objects()[0].related_model
<class 'polls.models.Choice'>
```

and compare it to the behavior on older versions:

```
>>> p._meta.get_all_related_objects()
[<RelatedObject: polls:choice related to poll>]
>>> p._meta.get_all_related_objects()[0].model
<class 'polls.models.Choice'>
```

To access the source model, you can use a pattern like this to write code that will work with both Django 1.8 and older versions:

```
for relation in opts.get_all_related_objects():
    to_model = getattr(relation, 'related_model', relation.model)
```

Also note that `get_all_related_objects()` is deprecated in 1.8. See the [upgrade guide](#) for the new API.

## Database backend API

The following changes to the database backend API are documented to assist those writing third-party backends in updating their code:

- BaseDatabaseXXX classes have been moved to `django.db.backends.base`. Please import them from the new locations:

```
from django.db.backends.base.base import BaseDatabaseWrapper
from django.db.backends.base.client import BaseDatabaseClient
from django.db.backends.base.creation import BaseDatabaseCreation
from django.db.backends.base.features import BaseDatabaseFeatures
from django.db.backends.base.introspection import BaseDatabaseIntrospection
from django.db.backends.base.introspection import FieldInfo, TableInfo
from django.db.backends.base.operations import BaseDatabaseOperations
from django.db.backends.base.schema import BaseDatabaseSchemaEditor
from django.db.backends.base.validation import BaseDatabaseValidation
```

- The `data_types`, `data_types_suffix`, and `data_type_check_constraints` attributes have moved from the `DatabaseCreation` class to `DatabaseWrapper`.
- The `SQLCompiler.as_sql()` method now takes a subquery parameter (#24164).
- The `BaseDatabaseOperations.date_interval_sql()` method now only takes a `timedelta` parameter.

### `django.contrib.admin`

- `AdminSite` no longer takes an `app_name` argument and its `app_name` attribute has been removed. The application name is always `admin` (as opposed to the instance name which you can still customize using `AdminSite(name="...")`).
- The `ModelAdmin.get_object()` method (private API) now takes a third argument named `from_field` in order to specify which field should match the provided `object_id`.
- The `ModelAdmin.response_delete()` method now takes a second argument named `obj_id` which is the serialized identifier used to retrieve the object before deletion.

### Default autoescaping of functions in `django.template.defaultfilters`

In order to make built-in template filters that output HTML “safe by default” when calling them in Python code, the following functions in `django.template.defaultfilters` have been changed to automatically escape their input value:

- `join`
- `linebreaksbr`
- `linebreaks_filter`
- `linenumbers`
- `unordered_list`
- `urlize`
- `urlizetrunc`

You can revert to the old behavior by specifying `autoescape=False` if you are passing trusted content. This change doesn’t have any effect when using the corresponding filters in templates.

## Miscellaneous

- `connections.queries` is now a read-only attribute.
- Database connections are considered equal only if they're the same object. They aren't hashable any more.
- `GZipMiddleware` used to disable compression for some content types when the request is from Internet Explorer, in order to work around a bug in IE6 and earlier. This behavior could affect performance on IE7 and later. It was removed.
- `URLField.to_python` no longer adds a trailing slash to pathless URLs.
- The `length` template filter now returns 0 for an undefined variable, rather than an empty string.
- `ForeignKey.default_error_message['invalid']` has been changed from `'%(model)s instance with pk %(pk)r does not exist.'` to `'%(model)s instance with %(field)s %(value)r does not exist.'` If you are using this message in your own code, please update the list of interpolated parameters. Internally, Django will continue to provide the `pk` parameter in `params` for backwards compatibility.
- `UserCreationForm.error_messages['duplicate_username']` is no longer used. If you wish to customize that error message, *override it on the form* using the 'unique' key in `Meta.error_messages['username']` or, if you have a custom form field for 'username', using the the 'unique' key in its `error_messages` argument.
- The block `usertools` in the `base.html` template of `django.contrib.admin` now requires the `has_permission` context variable to be set. If you have any custom admin views that use this template, update them to pass `AdminSite.has_permission()` as this new variable's value or simply include `AdminSite.each_context(request)` in the context.
- Internal changes were made to the `ClearableFileInput` widget to allow more customization. The undocumented `url_markup_template` attribute was removed in favor of `template_with_initial`.
- For consistency with other major vendors, the `en_GB` locale now has Monday as the first day of the week.
- Seconds have been removed from any locales that had them in `TIME_FORMAT`, `DATETIME_FORMAT`, or `SHORT_DATETIME_FORMAT`.
- The default max size of the Oracle test tablespace has increased from 300M (or 200M, before 1.7.2) to 500M.
- `reverse()` and `reverse_lazy()` now return Unicode strings instead of byte strings.
- The `CacheClass` shim has been removed from all cache backends. These aliases were provided for backwards compatibility with Django 1.3. If you are still using them, please update your project to use the real class name found in the `BACKEND` key of the `CACHES` setting.
- By default, `call_command()` now always skips the check framework (unless you pass it `skip_checks=False`).
- When iterating over lines, `File` now uses `universal newlines`. The following are recognized as ending a line: the Unix end-of-line convention `'\n'`, the Windows convention `'\r\n'`, and the old Macintosh convention `'\r'`.
- The Memcached cache backends `MemcachedCache` and `PyLibMCCache` will delete a key if `set()` fails. This is necessary to ensure the `cache_db` session store always fetches the most current session data.
- Private APIs `override_template_loaders` and `override_with_test_loader` in `django.test.utils` were removed. Override `TEMPLATES` with `override_settings` instead.
- Warnings from the MySQL database backend are no longer converted to exceptions when `DEBUG` is `True`.
- `HttpRequest` now has a simplified `repr` (e.g. `<WSGIRequest: GET '/somepath/'>`). This won't change the behavior of the `SafeExceptionReporterFilter` class.

- Class-based views that use `ModelFormMixin` will raise an `ImproperlyConfigured` exception when both the `fields` and `form_class` attributes are specified. Previously, `fields` was silently ignored.
- When following redirects, the test client now raises `RedirectCycleError` if it detects a loop or hits a maximum redirect limit (rather than passing silently).
- Translatable strings set as the `default` parameter of the field are cast to concrete strings later, so the return type of `Field.get_default()` is different in some cases. There is no change to default values which are the result of a callable.
- `GenericIPAddressField.empty_strings_allowed` is now `False`. Database backends that interpret empty strings as null (only Oracle among the backends that Django includes) will no longer convert null values back to an empty string. This is consistent with other backends.
- When the `leave_locale_alone` attribute is `False`, translations are now deactivated instead of forcing the “en-us” locale. In the case your models contained non-English strings and you counted on English translations to be activated in management commands, this will not happen any longer. It might be that new database migrations are generated (once) after migrating to 1.8.
- `django.utils.translation.get_language()` now returns `None` instead of `LANGUAGE_CODE` when translations are temporarily deactivated.
- When a translation doesn’t exist for a specific literal, the fallback is now taken from the `LANGUAGE_CODE` language (instead of from the untranslated `msgid` message).
- The `name` field of `django.contrib.contenttypes.models.ContentType` has been removed by a migration and replaced by a property. That means it’s not possible to query or filter a `ContentType` by this field any longer.

Be careful if you upgrade to Django 1.8 and skip Django 1.7. If you run `manage.py migrate --fake`, this migration will be skipped and you’ll see a `RuntimeError: Error creating new content types. exception because the name column won’t be dropped from the database.` Use `manage.py migrate --fake-initial` to fake only the initial migration instead.

- The new `migrate --fake-initial` option allows faking initial migrations. In 1.7, initial migrations were always automatically faked if all tables created in an initial migration already existed.
- An app *without* migrations with a `ForeignKey` to an app *with* migrations may now result in a foreign key constraint error when migrating the database or running tests. In Django 1.7, this could fail silently and result in a missing constraint. To resolve the error, add migrations to the app without them.

## Features deprecated in 1.8

### Selected methods in `django.db.models.options.Options`

As part of the formalization of the `Model._meta` API (from the `django.db.models.options.Options` class), a number of methods have been deprecated and will be removed in Django 1.10:

- `get_all_field_names()`
- `get_all_related_objects()`
- `get_all_related_objects_with_model()`
- `get_all_related_many_to_many_objects()`
- `get_all_related_m2m_objects_with_model()`
- `get_concrete_fields_with_model()`
- `get_field_by_name()`

- `get_fields_with_model()`
- `get_m2m_with_model()`

A *migration guide* has been provided to assist in converting your code from the old API to the new, official API.

### Loading `cycle` and `firstof` template tags from `future` library

Django 1.6 introduced `{% load cycle from future %}` and `{% load firstof from future %}` syntax for forward compatibility of the `cycle` and `firstof` template tags. This syntax is now deprecated and will be removed in Django 1.10. You can simply remove the `{% load ... from future %}` tags.

### `django.conf.urls.patterns()`

In the olden days of Django, it was encouraged to reference views as strings in `urlpatterns`:

```
urlpatterns = patterns('',
    url('^$', 'myapp.views.myview'),
)
```

and Django would magically import `myapp.views.myview` internally and turn the string into a real function reference. In order to reduce repetition when referencing many views from the same module, the `patterns()` function takes a required initial `prefix` argument which is prepended to all views-as-strings in that set of `urlpatterns`:

```
urlpatterns = patterns('myapp.views',
    url('^$', 'myview'),
    url('^other/$', 'otherview'),
)
```

In the modern era, we have updated the tutorial to instead recommend importing your views module and referencing your view functions (or classes) directly. This has a number of advantages, all deriving from the fact that we are using normal Python in place of “Django String Magic”: the errors when you mistype a view name are less obscure, IDEs can help with autocompletion of view names, etc.

So these days, the above use of the `prefix` arg is much more likely to be written (and is better written) as:

```
from myapp import views

urlpatterns = patterns('',
    url('^$', views.myview),
    url('^other/$', views.otherview),
)
```

Thus `patterns()` serves little purpose and is a burden when teaching new users (answering the newbie’s question “why do I need this empty string as the first argument to `patterns()`?”). For these reasons, we are deprecating it. Updating your code is as simple as ensuring that `urlpatterns` is a list of `django.conf.urls.url()` instances. For example:

```
from django.conf.urls import url
from myapp import views

urlpatterns = [
    url('^$', views.myview),
    url('^other/$', views.otherview),
]
```

## Passing a string as view to `url()`

Related to the previous item, referencing views as strings in the `url()` function is deprecated. Pass the callable view as described in the previous section instead.

## Template-related settings

As a consequence of the multiple template engines refactor, several settings are deprecated in favor of `TEMPLATES`:

- `ALLOWED_INCLUDE_ROOTS`
- `TEMPLATE_CONTEXT_PROCESSORS`
- `TEMPLATE_DEBUG`
- `TEMPLATE_DIRS`
- `TEMPLATE_LOADERS`
- `TEMPLATE_STRING_IF_INVALID`

## `django.core.context_processors`

Built-in template context processors have been moved to `django.template.context_processors`.

## `django.test.SimpleTestCase.urls`

The attribute `SimpleTestCase.urls` for specifying URLconf configuration in tests has been deprecated and will be removed in Django 1.10. Use `@override_settings(ROOT_URLCONF=...)` instead.

## prefix argument to `i18n_patterns()`

Related to the previous item, the prefix argument to `django.conf.urls.i18n.i18n_patterns()` has been deprecated. Simply pass a list of `django.conf.urls.url()` instances instead.

## Using an incorrect count of unpacked values in the `for` template tag

Using an incorrect count of unpacked values in `for` tag will raise an exception rather than fail silently in Django 1.10.

## Passing a dotted path to `reverse()` and `url`

Reversing URLs by Python path is an expensive operation as it causes the path being reversed to be imported. This behavior has also resulted in a security issue. Use *named URL patterns* for reversing instead.

If you are using `django.contrib.sitemaps`, add the `name` argument to the `url` that references `django.contrib.sitemaps.views.sitemap()`:

```
from django.contrib.sitemaps.views import sitemap

url(r'^sitemap\.xml$', sitemap, {'sitemaps': sitemaps},
    name='django.contrib.sitemaps.views.sitemap')
```

to ensure compatibility when reversing by Python path is removed in Django 1.10.

Similarly for GIS sitemaps, add `name='django.contrib.gis.sitemaps.views.kml'` or `name='django.contrib.gis.sitemaps.views.kmz'`.

If you are using a Python path for the `LOGIN_URL` or `LOGIN_REDIRECT_URL` setting, use the name of the `url()` instead.

## Aggregate methods and modules

The `django.db.models.sql.aggregates` and `django.contrib.gis.db.models.sql.aggregates` modules (both private API), have been deprecated as `django.db.models.aggregates` and `django.contrib.gis.db.models.aggregates` are now also responsible for SQL generation. The old modules will be removed in Django 1.10.

If you were using the old modules, see *Query Expressions* for instructions on rewriting custom aggregates using the new stable API.

The following methods and properties of `django.db.models.sql.query.Query` have also been deprecated and the backwards compatibility shims will be removed in Django 1.10:

- `Query.aggregates`, replaced by `annotations`.
- `Query.aggregate_select`, replaced by `annotation_select`.
- `Query.add_aggregate()`, replaced by `add_annotation()`.
- `Query.set_aggregate_mask()`, replaced by `set_annotation_mask()`.
- `Query.append_aggregate_mask()`, replaced by `append_annotation_mask()`.

## Extending management command arguments through `Command.option_list`

Management commands now use `argparse` instead of `optparse` to parse command-line arguments passed to commands. This also means that the way to add custom arguments to commands has changed: instead of extending the `option_list` class list, you should now override the `add_arguments()` method and add arguments through `argparse.add_argument()`. See *this example* for more details.

## `django.core.management.NoArgsCommand`

The class `NoArgsCommand` is now deprecated and will be removed in Django 1.10. Use `BaseCommand` instead, which takes no arguments by default.

## Listing all migrations in a project

The `--list` option of the `migrate` management command is deprecated and will be removed in Django 1.10. Use `showmigrations` instead.

## `cache_choices` option of `ModelChoiceField` and `ModelMultipleChoiceField`

`ModelChoiceField` and `ModelMultipleChoiceField` took an undocumented, untested option `cache_choices`. This cached querysets between multiple renderings of the same `Form` object. This option is subject to an accelerated deprecation and will be removed in Django 1.9.

### `django.template.resolve_variable()`

The function has been informally marked as “Deprecated” for some time. Replace `resolve_variable(path, context)` with `django.template.Variable(path).resolve(context)`.

### `django.contrib.webdesign`

It provided the *lorem* template tag which is now included in the built-in tags. Simply remove `'django.contrib.webdesign'` from `INSTALLED_APPS` and `{% load webdesign %}` from your templates.

### error\_message argument to `django.forms.RegexField`

It provided backwards compatibility for pre-1.0 code, but its functionality is redundant. Use `Field.error_messages['invalid']` instead.

### Old `unordered_list` syntax

An older (pre-1.0), more restrictive and verbose input format for the `unordered_list` template filter has been deprecated:

```
['States', [['Kansas', [['Lawrence', []], ['Topeka', []]]], ['Illinois', []]]]
```

Using the new syntax, this becomes:

```
['States', ['Kansas', ['Lawrence', 'Topeka'], 'Illinois']]
```

### `django.forms.Field._has_changed()`

Rename this method to `has_changed()` by removing the leading underscore. The old name will still work until Django 1.10.

### `django.utils.html.remove_tags()` and `removetags` template filter

`django.utils.html.remove_tags()` as well as the template filter `removetags` have been deprecated as they cannot guarantee safe output. Their existence is likely to lead to their use in security-sensitive contexts where they are not actually safe.

The unused and undocumented `django.utils.html.strip_entities()` function has also been deprecated.

### `is_admin_site` argument to `django.contrib.auth.views.password_reset()`

It's a legacy option that should no longer be necessary.

### SubfieldBase

`django.db.models.fields.subclassing.SubfieldBase` has been deprecated and will be removed in Django 1.10. Historically, it was used to handle fields where type conversion was needed when loading from the database, but it was not used in `.values()` calls or in aggregates. It has been replaced with `from_db_value()`.

The new approach doesn't call the `to_python()` method on assignment as was the case with `SubfieldBase`. If you need that behavior, reimplement the `Creator` class from Django's source code in your project.

### `django.utils.checksums`

The `django.utils.checksums` module has been deprecated and will be removed in Django 1.10. The functionality it provided (validating checksum using the Luhn algorithm) was undocumented and not used in Django. The module has been moved to the `django-localflavor` package (version 1.1+).

### `InlineAdminForm.original_content_type_id`

The `original_content_type_id` attribute on `InlineAdminForm` has been deprecated and will be removed in Django 1.10. Historically, it was used to construct the “view on site” URL. This URL is now accessible using the `absolute_url` attribute of the form.

### `django.views.generic.edit.FormMixin.get_form()`'s `form_class` argument

`FormMixin` subclasses that override the `get_form()` method should make sure to provide a default value for the `form_class` argument since it's now optional.

### Rendering templates loaded by `get_template()` with a Context

The return type of `get_template()` has changed in Django 1.8: instead of a `django.template.Template`, it returns a `Template` instance whose exact type depends on which backend loaded it.

Both classes provide a `render()` method, however, the former takes a `django.template.Context` as an argument while the latter expects a `dict`. This change is enforced through a deprecation path for Django templates.

Since it's easier to understand with examples, the *upgrade guide* shows how to adapt affected code.

All this also applies to `select_template()`.

### Template and Context classes in template responses

Some methods of `SimpleTemplateResponse` and `TemplateResponse` accepted `django.template.Context` and `django.template.Template` objects as arguments. They should now receive `dict` and backend-dependent template objects respectively.

This also applies to the return types if you have subclassed either template response class.

Check the *template response API documentation* for details.

### current\_app argument of template-related APIs

The following functions and classes will no longer accept a `current_app` parameter to set an URL namespace in Django 1.10:

- `django.shortcuts.render()`
- `django.template.Context()`
- `django.template.RequestContext()`
- `django.template.response.TemplateResponse()`

Set `request.current_app` instead, where `request` is the first argument to these functions or classes. If you're using a plain `Context`, use a `RequestContext` instead.

### dictionary and context\_instance arguments of rendering functions

The following functions will no longer accept the `dictionary` and `context_instance` parameters in Django 1.10:

- `django.shortcuts.render()`
- `django.shortcuts.render_to_response()`
- `django.template.loader.render_to_string()`

Use the `context` parameter instead. When `dictionary` is passed as a positional argument, which is the most common idiom, no changes are needed.

If you're passing a `Context` in `context_instance`, pass a `dict` in the `context` parameter instead. If you're passing a `RequestContext`, pass the `request` separately in the `request` parameter.

### dirs argument of template-finding functions

The following functions will no longer accept a `dirs` parameter to override `TEMPLATE_DIRS` in Django 1.10:

- `django.template.loader.get_template()`
- `django.template.loader.select_template()`
- `django.shortcuts.render()`
- `django.shortcuts.render_to_response()`

The parameter didn't work consistently across different template loaders and didn't work for included templates.

### django.template.loader.BaseLoader

`django.template.loader.BaseLoader` was renamed to `django.template.loaders.base.Loader`. If you've written a custom template loader that inherits `BaseLoader`, you must inherit `Loader` instead.

### django.test.utils.TestTemplateLoader

Private API `django.test.utils.TestTemplateLoader` is deprecated in favor of `django.template.loaders.locmem.Loader` and will be removed in Django 1.9.

## Support for the `max_length` argument on custom Storage classes

Storage subclasses should add `max_length=None` as a parameter to `get_available_name()` and/or `save()` if they override either method. Support for storages that do not accept this argument will be removed in Django 1.10.

## `qn` replaced by `compiler`

In previous Django versions, various internal ORM methods (mostly `as_sql` methods) accepted a `qn` (for “quote name”) argument, which was a reference to a function that quoted identifiers for sending to the database. In Django 1.8, that argument has been renamed to `compiler` and is now a full `SQLCompiler` instance. For backwards-compatibility, calling a `SQLCompiler` instance performs the same name-quoting that the `qn` function used to. However, this backwards-compatibility shim is immediately deprecated: you should rename your `qn` arguments to `compiler`, and call `compiler.quote_name_unless_alias(...)` where you previously called `qn(...)`.

## Default value of `RedirectView.permanent`

The default value of the `RedirectView.permanent` attribute will change from `True` to `False` in Django 1.9.

## Using `AuthenticationMiddleware` without `SessionAuthenticationMiddleware`

`django.contrib.auth.middleware.SessionAuthenticationMiddleware` was added in Django 1.7. In Django 1.7.2, its functionality was moved to `auth.get_user()` and, for backwards compatibility, enabled only if `'django.contrib.auth.middleware.SessionAuthenticationMiddleware'` appears in `MIDDLEWARE_CLASSES`.

In Django 1.10, session verification will be enabled regardless of whether or not `SessionAuthenticationMiddleware` is enabled (at which point `SessionAuthenticationMiddleware` will have no significance). You can add it to your `MIDDLEWARE_CLASSES` sometime before then to opt-in. Please read the *upgrade considerations* first.

## `django.contrib.sitemaps.FlatPageSitemap`

`django.contrib.sitemaps.FlatPageSitemap` has moved to `django.contrib.flatpages.sitemaps.FlatPageSitemap`. The old import location is deprecated and will be removed in Django 1.9.

## Model Field `related`

Private attribute `django.db.models.Field.related` is deprecated in favor of `Field.rel`. The latter is an instance of `django.db.models.fields.related.ForeignKeyRel` which replaces `django.db.models.related.RelatedObject`. The `django.db.models.related` module has been removed and the `Field.related` attribute will be removed in Django 1.10.

## `ssi` template tag

The `ssi` template tag allows files to be included in a template by absolute path. This is of limited use in most deployment situations, and the `include` tag often makes more sense. This tag is now deprecated and will be removed in Django 1.10.

## = as comparison operator in if template tag

Using a single equals sign with the `{% if %}` template tag for equality testing was undocumented and untested. It's now deprecated in favor of `==`.

## %(<foo>)s syntax in ModelFormMixin.success\_url

The legacy `%(<foo>)s` syntax in `ModelFormMixin.success_url` is deprecated and will be removed in Django 1.10.

## GeoQuerySet aggregate methods

The `collect()`, `extent()`, `extent3d()`, `make_line()`, and `unionagg()` aggregate methods are deprecated and should be replaced by their function-based aggregate equivalents (`Collect`, `Extent`, `Extent3D`, `MakeLine`, and `Union`).

## Signature of the allow\_migrate router method

The signature of the `allow_migrate()` method of database routers has changed from `allow_migrate(db, model)` to `allow_migrate(db, app_label, model_name=None, **hints)`.

When `model_name` is set, the value that was previously given through the `model` positional argument may now be found inside the `hints` dictionary under the key `'model'`.

After switching to the new signature the router will also be called by the `RunPython` and `RunSQL` operations.

## Features removed in 1.8

These features have reached the end of their deprecation cycle and are removed in Django 1.8. See [Features deprecated in 1.6](#) for details, including how to remove usage of these features.

- `django.contrib.comments` is removed.
- The following transaction management APIs are removed:
  - `TransactionMiddleware`
  - the decorators and context managers `autocommit`, `commit_on_success`, and `commit_manually`, defined in `django.db.transaction`
  - the functions `commit_unless_managed` and `rollback_unless_managed`, also defined in `django.db.transaction`
  - the `TRANSACTIONS_MANAGED` setting
- The `cycle` and `firstof` template tags auto-escape their arguments.
- The `SEND_BROKEN_LINK_EMAILS` setting is removed.
- `django.middleware.doc.XViewMiddleware` is removed.
- The `Model._meta.module_name` alias is removed.
- The backward compatible shims introduced to rename `get_query_set` and similar queryset methods are removed. This affects the following classes: `BaseModelAdmin`, `ChangeList`,

BaseCommentNode, GenericForeignKey, Manager, SingleRelatedObjectDescriptor and ReverseSingleRelatedObjectDescriptor.

- The backward compatible shims introduced to rename the attributes `ChangeList.root_query_set` and `ChangeList.query_set` are removed.
- `django.views.defaults.shortcut` and `django.conf.urls.shortcut` are removed.
- Support for the Python Imaging Library (PIL) module is removed.
- The following private APIs are removed:
  - `django.db.backend`
  - `django.db.close_connection()`
  - `django.db.backends.creation.BaseDatabaseCreation.set_autocommit()`
  - `django.db.transaction.is_managed()`
  - `django.db.transaction.managed()`
- `django.forms.widgets.RadioInput` is removed.
- The module `django.test.simple` and the class `django.test.simple.DjangoTestSuiteRunner` are removed.
- The module `django.test._doctest` is removed.
- The `CACHE_MIDDLEWARE_ANONYMOUS_ONLY` setting is removed. This change affects both `django.middleware.cache.CacheMiddleware` and `django.middleware.cache.UpdateCacheMiddleware` despite the lack of a deprecation warning in the latter class.
- Usage of the hard-coded *Hold down “Control”, or “Command” on a Mac, to select more than one.* string to override or append to user-provided `help_text` in forms for `ManyToMany` model fields is not performed by Django anymore either at the model or forms layer.
- The `Model._meta.get_(add|change|delete)_permission` methods are removed.
- The session key `django_language` is no longer read for backwards compatibility.
- Geographic Sitemaps are removed (`django.contrib.gis.sitemaps.views.index` and `django.contrib.gis.sitemaps.views.sitemap`).
- `django.utils.html.fix_ampersands`, the `fix_ampersands` template filter, and `django.utils.html.clean_html` are removed.

## 9.1.4 1.7 release

### Django 1.7.11 release notes

November 24, 2015

Django 1.7.11 fixes a security issue and a data loss bug in 1.7.10.

#### Fixed settings leak possibility in date template filter

If an application allows users to specify an unvalidated format for dates and passes this format to the `date` filter, e.g. `{{ last_updated|date:user_date_format }}`, then a malicious user could obtain any secret in the application’s settings by specifying a settings key instead of a date format. e.g. `"SECRET_KEY"` instead of `"j/m/Y"`.

To remedy this, the underlying function used by the `date` template filter, `django.utils.formats.get_format()`, now only allows accessing the date/time formatting settings.

## Bugfixes

- Fixed a data loss possibility with `Prefetch` if `to_attr` is set to a `ManyToManyField` (#25693).

## Django 1.7.10 release notes

August 18, 2015

Django 1.7.10 fixes a security issue in 1.7.9.

### Denial-of-service possibility in `logout()` view by filling session store

Previously, a session could be created when anonymously accessing the `django.contrib.auth.views.logout()` view (provided it wasn't decorated with `login_required()` as done in the admin). This could allow an attacker to easily create many new session records by sending repeated requests, potentially filling up the session store or causing other users' session records to be evicted.

The `SessionMiddleware` has been modified to no longer create empty session records, including when `SESSION_SAVE_EVERY_REQUEST` is active.

Additionally, the `contrib.sessions.backends.base.SessionBase.flush()` and `cache_db.SessionStore.flush()` methods have been modified to avoid creating a new empty session. Maintainers of third-party session backends should check if the same vulnerability is present in their backend and correct it if so.

## Django 1.7.9 release notes

July 8, 2015

Django 1.7.9 fixes several security issues and bugs in 1.7.8.

### Denial-of-service possibility by filling session store

In previous versions of Django, the session backends created a new empty record in the session storage anytime `request.session` was accessed and there was a session key provided in the request cookies that didn't already have a session record. This could allow an attacker to easily create many new session records simply by sending repeated requests with unknown session keys, potentially filling up the session store or causing other users' session records to be evicted.

The built-in session backends now create a session record only if the session is actually modified; empty session records are not created. Thus this potential DoS is now only possible if the site chooses to expose a session-modifying view to anonymous users.

As each built-in session backend was fixed separately (rather than a fix in the core sessions framework), maintainers of third-party session backends should check whether the same vulnerability is present in their backend and correct it if so.

## Header injection possibility since validators accept newlines in input

Some of Django's built-in validators (*EmailValidator*, most seriously) didn't prohibit newline characters (due to the usage of `$` instead of `\Z` in the regular expressions). If you use values with newlines in HTTP response or email headers, you can suffer from header injection attacks. Django itself isn't vulnerable because *HttpResponse* and the mail sending utilities in *django.core.mail* prohibit newlines in HTTP and SMTP headers, respectively. While the validators have been fixed in Django, if you're creating HTTP responses or email messages in other ways, it's a good idea to ensure that those methods prohibit newlines as well. You might also want to validate that any existing data in your application doesn't contain unexpected newlines.

*validate\_ipv4\_address()*, *validate\_slug()*, and *URLValidator* are also affected, however, as of Django 1.6 the *GenericIPAddressField*, *IPAddressField*, *SlugField*, and *URLField* form fields which use these validators all strip the input, so the possibility of newlines entering your data only exists if you are using these validators outside of the form fields.

The undocumented, internally unused *validate\_integer()* function is now stricter as it validates using a regular expression instead of simply casting the value using *int()* and checking if an exception was raised.

## Bugfixes

- Prevented the loss of `null/not null` column properties during field renaming of MySQL databases (#24817).
- Fixed *SimpleTestCase.assertRaisesMessage()* on Python 2.7.10 (#24903).

## Django 1.7.8 release notes

May 1, 2015

Django 1.7.8 fixes:

- Database introspection with SQLite 3.8.9 (released April 8, 2015) (#24637).
- A database table name quoting regression in 1.7.2 (#24605).
- The loss of `null/not null` column properties during field alteration of MySQL databases (#24595).

## Django 1.7.7 release notes

March 18, 2015

Django 1.7.7 fixes several bugs and security issues in 1.7.6.

## Denial-of-service possibility with `strip_tags()`

Last year *strip\_tags()* was changed to work iteratively. The problem is that the size of the input it's processing can increase on each iteration which results in an infinite loop in *strip\_tags()*. This issue only affects versions of Python that haven't received a bugfix in *HTMLParser*; namely Python < 2.7.7 and 3.3.5. Some operating system vendors have also backported the fix for the Python bug into their packages of earlier versions.

To remedy this issue, *strip\_tags()* will now return the original input if it detects the length of the string it's processing increases. Remember that absolutely NO guarantee is provided about the results of *strip\_tags()* being HTML safe. So NEVER mark safe the result of a *strip\_tags()* call without escaping it first, for example with *escape()*.

## Mitigated possible XSS attack via user-supplied redirect URLs

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()` and `is_safe_url()`) to redirect the user to an “on success” URL. The security checks for these redirects (namely `django.utils.http.is_safe_url()`) accepted URLs with leading control characters and so considered URLs like `\x08javascript:... safe`. This issue doesn’t affect Django currently, since we only put this URL into the `Location` response header and browsers seem to ignore JavaScript there. Browsers we tested also treat URLs prefixed with control characters such as `%08//example.com` as relative paths so redirection to an unsafe target isn’t a problem either.

However, if a developer relies on `is_safe_url()` to provide safe redirect targets and puts such a URL into a link, they could suffer from an XSS attack as some browsers such as Google Chrome ignore control characters at the start of a URL in an anchor `href`.

## Bugfixes

- Fixed renaming of classes in migrations where renaming a subclass would cause incorrect state to be recorded for objects that referenced the superclass (#24354).
- Stopped writing migration files in dry run mode when merging migration conflicts. When `makemigrations --merge` is called with `verbosity=3` the migration file is written to `stdout` (#24427).

## Django 1.7.6 release notes

March 9, 2015

Django 1.7.6 fixes a security issue and several bugs in 1.7.5.

## Mitigated an XSS attack via properties in `ModelAdmin.readonly_fields`

The `ModelAdmin.readonly_fields` attribute in the Django admin allows displaying model fields and model attributes. While the former were correctly escaped, the latter were not. Thus untrusted content could be injected into the admin, presenting an exploitation vector for XSS attacks.

In this vulnerability, every model attribute used in `readonly_fields` that is not an actual model field (e.g. a `property`) will **fail to be escaped** even if that attribute is not marked as safe. In this release, autoescaping is now correctly applied.

## Bugfixes

- Fixed crash when coercing `ManyRelatedManager` to a string (#24352).
- Fixed a bug that prevented migrations from adding a foreign key constraint when converting an existing field to a foreign key (#24447).

## Django 1.7.5 release notes

February 25, 2015

Django 1.7.5 fixes several bugs in 1.7.4.

## Bugfixes

- Reverted a fix that prevented a migration crash when unapplying `contrib.contenttypes`'s or `contrib.auth`'s first migration (#24075) due to severe impact on the test performance (#24251) and problems in multi-database setups (#24298).
- Fixed a regression that prevented custom fields inheriting from `ManyToManyField` from being recognized in migrations (#24236).
- Fixed crash in `contrib.sites` migrations when a default database isn't used (#24332).
- Added the ability to set the isolation level on PostgreSQL with `psycopg2 ≥ 2.4.2` (#24318). It was advertised as a new feature in Django 1.6 but it didn't work in practice.
- Formats for the Azerbaijani locale (`az`) have been added.

## Django 1.7.4 release notes

January 27, 2015

Django 1.7.4 fixes several bugs in 1.7.3.

## Bugfixes

- Fixed a migration crash when unapplying `contrib.contenttypes`'s or `contrib.auth`'s first migration (#24075).
- Made the migration's `RenameModel` operation rename `ManyToManyField` tables (#24135).
- Fixed a migration crash on MySQL when migrating from a `OneToOneField` to a `ForeignKey` (#24163).
- Prevented the `static.serve` view from producing `ResourceWarnings` in certain circumstances (security fix regression, #24193).
- Fixed schema check for `ManyToManyField` to look for internal type instead of checking class instance, so you can write custom m2m-like fields with the same behavior. (#24104).

## Django 1.7.3 release notes

January 13, 2015

Django 1.7.3 fixes several security issues and bugs in 1.7.2.

## WSGI header spoofing via underscore/dash conflation

When HTTP headers are placed into the WSGI environ, they are normalized by converting to uppercase, converting all dashes to underscores, and prepending `HTTP_`. For instance, a header `X-Auth-User` would become `HTTP_X_AUTH_USER` in the WSGI environ (and thus also in Django's `request.META` dictionary).

Unfortunately, this means that the WSGI environ cannot distinguish between headers containing dashes and headers containing underscores: `X-Auth-User` and `X-Auth_User` both become `HTTP_X_AUTH_USER`. This means that if a header is used in a security-sensitive way (for instance, passing authentication information along from a front-end proxy), even if the proxy carefully strips any incoming value for `X-Auth-User`, an attacker may be able to provide an `X-Auth_User` header (with underscore) and bypass this protection.

In order to prevent such attacks, both Nginx and Apache 2.4+ strip all headers containing underscores from incoming requests by default. Django’s built-in development server now does the same. Django’s development server is not recommended for production use, but matching the behavior of common production servers reduces the surface area for behavior changes during deployment.

### Mitigated possible XSS attack via user-supplied redirect URLs

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()` and `isbn`) to redirect the user to an “on success” URL. The security checks for these redirects (namely `django.utils.http.is_safe_url()`) didn’t strip leading whitespace on the tested URL and as such considered URLs like `\njavascript:... safe`. If a developer relied on `is_safe_url()` to provide safe redirect targets and put such a URL into a link, they could suffer from a XSS attack. This bug doesn’t affect Django currently, since we only put this URL into the `Location` response header and browsers seem to ignore JavaScript there.

### Denial-of-service attack against `django.views.static.serve`

In older versions of Django, the `django.views.static.serve()` view read the files it served one line at a time. Therefore, a big file with no newlines would result in memory usage equal to the size of that file. An attacker could exploit this and launch a denial-of-service attack by simultaneously requesting many large files. This view now reads the file in chunks to prevent large memory usage.

Note, however, that this view has always carried a warning that it is not hardened for production use and should be used only as a development aid. Now may be a good time to audit your project and serve your files in production using a real front-end web server if you are not doing so.

### Database denial-of-service with `ModelMultipleChoiceField`

Given a form that uses `ModelMultipleChoiceField` and `show_hidden_initial=True` (not a documented API), it was possible for a user to cause an unreasonable number of SQL queries by submitting duplicate values for the field’s data. The validation logic in `ModelMultipleChoiceField` now deduplicates submitted values to address this issue.

## Bugfixes

- The default iteration count for the PBKDF2 password hasher has been increased by 25%. This part of the normal major release process was inadvertently omitted in 1.7. This backwards compatible change will not affect users who have subclassed `django.contrib.auth.hashers.PBKDF2PasswordHasher` to change the default value.
- Fixed a crash in the CSRF middleware when handling non-ASCII referer header (#23815).
- Fixed a crash in the `django.contrib.auth.redirect_to_login` view when passing a `reverse_lazy()` result on Python 3 (#24097).
- Added correct formats for Greek (ε1) (#23967).
- Fixed a migration crash when unapplying a migration where multiple operations interact with the same model (#24110).

## Django 1.7.2 release notes

January 2, 2015

Django 1.7.2 fixes several bugs in 1.7.1.

Additionally, Django's vendored version of six, `django.utils.six`, has been upgraded to the latest release (1.9.0).

### Bugfixes

- Fixed migration's renaming of auto-created many-to-many tables when changing `Meta.db_table` (#23630).
- Fixed a migration crash when adding an explicit `id` field to a model on SQLite (#23702).
- Added a warning for duplicate models when a module is reloaded. Previously a `RuntimeError` was raised every time two models clashed in the app registry. (#23621).
- Prevented `flush` from loading initial data for migrated apps (#23699).
- Fixed a `makemessages` regression in 1.7.1 when `STATIC_ROOT` has the default `None` value (#23717).
- Added GeoDjango compatibility with `mysqlclient` database driver.
- Fixed MySQL 5.6+ crash with `GeometryFields` in migrations (#23719).
- Fixed a migration crash when removing a field that is referenced in `AlterIndexTogether` or `AlterUniqueTogether` (#23614).
- Updated the first day of the week in the Ukrainian locale to Monday.
- Added support for transactional spatial metadata initialization on SpatiaLite 4.1+ (#23152).
- Fixed a migration crash that prevented changing a nullable field with a default to non-nullable with the same default (#23738).
- Fixed a migration crash when adding `GeometryFields` with `blank=True` on PostGIS (#23731).
- Allowed usage of `DateTimeField()` as `Transform.output_field` (#23420).
- Fixed a migration serializing bug involving `float("nan")` and `float("inf")` (#23770).
- Fixed a regression where custom form fields having a `queryset` attribute but no `limit_choices_to` could not be used in a `ModelForm` (#23795).
- Fixed a custom field type validation error with MySQL backend when `db_type` returned `None` (#23761).
- Fixed a migration crash when a field is renamed that is part of an `index_together` (#23859).
- Fixed `squashmigrations` to respect the `--no-optimize` parameter (#23799).
- Made `RenameModel` reversible (#22248).
- Avoided unnecessary rollbacks of migrations from other apps when migrating backwards (#23410).
- Fixed a rare query error when using deeply nested subqueries (#23605).
- Fixed a crash in migrations when deleting a field that is part of a `index/unique_together` constraint (#23794).
- Fixed `django.core.files.File.__repr__()` when the file's name contains Unicode characters (#23888).
- Added missing context to the admin's `delete_selected` view that prevented custom site header, etc. from appearing (#23898).

- Fixed a regression with dynamically generated inlines and allowed field references in the admin (#23754).
- Fixed an infinite loop bug for certain cyclic migration dependencies, and made the error message for cyclic dependencies much more helpful.
- Added missing `index_together` handling for SQLite (#23880).
- Fixed a crash when RunSQL SQL content was collected by the schema editor, typically when using `sqlmigrate` (#23909).
- Fixed a regression in `contrib.admin` add/change views which caused some `ModelAdmin` methods to receive the incorrect `obj` value (#23934).
- Fixed `runserver` crash when socket error message contained Unicode characters (#23946).
- Fixed serialization of `type` when adding a `deconstruct()` method (#23950).
- Prevented the `django.contrib.auth.middleware.SessionAuthenticationMiddleware` from setting a "Vary: Cookie" header on all responses (#23939).
- Fixed a crash when adding `blank=True` to `TextField()` on MySQL (#23920).
- Fixed index creation by the migration infrastructure, particularly when dealing with PostgreSQL specific `{text|varchar}_pattern_ops` indexes (#23954).
- Fixed bug in `makemigrations` that created broken migration files when dealing with multiple table inheritance and inheriting from more than one model (#23956).
- Fixed a crash when a `MultiValueField` has invalid data (#23674).
- Fixed a crash in the admin when using "Save as new" and also deleting a related inline (#23857).
- Always converted `related_name` to text (unicode), since that is required on Python 3 for interpolation. Removed conversion of `related_name` to text in migration deconstruction (#23455 and #23982).
- Enlarged the sizes of tablespaces which are created by default for testing on Oracle (the main tablespace was increased from 200M to 300M and the temporary tablespace from 100M to 150M). This was required to accommodate growth in Django's own test suite (#23969).
- Fixed `timesince` filter translations in Korean (#23989).
- Fixed the SQLite `SchemaEditor` to properly add defaults in the absence of a user specified default. For example, a `CharField` with `blank=True` didn't set existing rows to an empty string which resulted in a crash when adding the `NOT NULL` constraint (#23987).
- `makemigrations` no longer prompts for a default value when adding `TextField()` or `CharField()` without a default (#23405).
- Fixed a migration crash when adding `order_with_respect_to` to a table with existing rows (#23983).
- Restored the `pre_migrate` signal if all apps have migrations (#23975).
- Made admin system checks run for custom `AdminSites` (#23497).
- Ensured the app registry is fully populated when unpickling models. When an external script (like a queuing infrastructure) reloads pickled models, it could crash with an `AppRegistryNotReady` exception (#24007).
- Added quoting to field indexes in the SQL generated by migrations to prevent a crash when the index name requires it (##24015).
- Added `datetime.time` support to migrations questioner (#23998).
- Fixed `admindocs` crash on apps installed as eggs (#23525).

- Changed migrations autodetector to generate an `AlterModelOptions` operation instead of `DeleteModel` and `CreateModel` operations when changing `Meta.managed`. This prevents data loss when changing managed from `False` to `True` and vice versa (#24037).
- Enabled the `sqlsequencereset` command on apps with migrations (#24054).
- Added tablespace SQL to apps with migrations (#24051).
- Corrected `contrib.sites` default site creation in a multiple database setup (#24000).
- Restored support for objects that aren't `str` or `bytes` in `django.utils.safestring.mark_for_escaping()` on Python 3.
- Supported strings escaped by third-party libraries with the `__html__` convention in the template engine (#23831).
- Prevented extraneous `DROP DEFAULT SQL` in migrations (#23581).
- Restored the ability to use more than five levels of subqueries (#23758).
- Fixed crash when `ValidationError` is initialized with a `ValidationError` that is initialized with a dictionary (#24008).
- Prevented a crash on apps without migrations when running `migrate --list` (#23366).

## Django 1.7.1 release notes

October 22, 2014

Django 1.7.1 fixes several bugs in 1.7.

### Bugfixes

- Allowed related many-to-many fields to be referenced in the admin (#23604).
- Added a more helpful error message if you try to migrate an app without first creating the `contenttypes` table (#22411).
- Modified migrations dependency algorithm to avoid possible infinite recursion.
- Fixed a `UnicodeDecodeError` when the `flush` error message contained Unicode characters (#22882).
- Reinstated missing `CHECK SQL` clauses which were omitted on some backends when not using migrations (#23416).
- Fixed serialization of `type` objects in migrations (#22951).
- Allowed inline and hidden references to admin fields (#23431).
- The `@deconstructible` decorator now fails with a `ValueError` if the decorated object cannot automatically be imported (#23418).
- Fixed a typo in an `inlineformset_factory()` error message that caused a crash (#23451).
- Restored the ability to use `ABSOLUTE_URL_OVERRIDES` with the `'auth.User'` model (#11775). As a side effect, the setting now adds a `get_absolute_url()` method to any model that appears in `ABSOLUTE_URL_OVERRIDES` but doesn't define `get_absolute_url()`.
- Avoided masking some `ImportError` exceptions during application loading (#22920).
- Empty `index_together` or `unique_together` model options no longer results in infinite migrations (#23452).

- Fixed crash in `contrib.sitemaps` if `lastmod` returned a date rather than a datetime (#23403).
- Allowed migrations to work with `app_labels` that have the same last part (e.g. `django.contrib.auth` and `vendor.auth`) (#23483).
- Restored the ability to deepcopy `F` objects (#23492).
- Formats for Welsh (`cy`) and several Chinese locales (`zh_CN`, `zh_Hans`, `zh_Hant` and `zh_TW`) have been added. Formats for Macedonian have been fixed (trailing dot removed, #23532).
- Added quoting of constraint names in the SQL generated by migrations to prevent crash with uppercase characters in the name (#23065).
- Fixed renaming of models with a self-referential many-to-many field (`ManyToManyField('self')`) (#23503).
- Added the `get_extra()`, `get_max_num()`, and `get_min_num()` hooks to `GenericInlineModelAdmin` (#23539).
- Made `migrations.RunSQL` no longer require percent sign escaping. This is now consistent with `cursor.execute()` (#23426).
- Made the `SERIALIZE` entry in the `TEST` dictionary usable (#23421).
- Fixed bug in migrations that prevented foreign key constraints to unmanaged models with a custom primary key (#23415).
- Added `SchemaEditor` for MySQL GIS backend so that spatial indexes will be created for apps with migrations (#23538).
- Added `SchemaEditor` for Oracle GIS backend so that spatial metadata and indexes will be created for apps with migrations (#23537).
- Coerced the `related_name` model field option to unicode during migration generation to generate migrations that work with both Python 2 and 3 (#23455).
- Fixed `MigrationWriter` to handle builtin types without imports (#23560).
- Fixed deepcopy on `ErrorList` (#23594).
- Made the `admindocs` view to browse view details check if the view specified in the URL exists in the URL-conf. Previously it was possible to import arbitrary packages from the Python path. This was not considered a security issue because `admindocs` is only accessible to staff users (#23601).
- Fixed `UnicodeDecodeError` crash in `AdminEmailHandler` with non-ASCII characters in the request (#23593).
- Fixed missing `get_or_create` and `update_or_create` on related managers causing `IntegrityError` (#23611).
- Made `urlsafe_base64_decode()` return the proper type (byte string) on Python 3 (#23333).
- `makemigrations` can now serialize timezone-aware values (#23365).
- Added a prompt to the migrations questioner when removing the null constraint from a field to prevent an `IntegrityError` on existing NULL rows (#23609).
- Fixed generic relations in `ModelAdmin.list_filter` (#23616).
- Restored RFC compliance for the SMTP backend on Python 3 (#23063).
- Fixed a crash while parsing cookies containing invalid content (#23638).
- The system check framework now raises error **models.E020** when the class method `Model.check()` is unreachable (#23615).

- Made the Oracle test database creation drop the test user in the event of an unclean exit of a previous test run (#23649).
- Fixed `makemigrations` to detect changes to `Meta.db_table` (#23629).
- Fixed a regression when feeding the Django test client with an empty data string (#21740).
- Fixed a regression in `makemessages` where static files were unexpectedly ignored (#23583).

### Django 1.7 release notes

September 2, 2014

Welcome to Django 1.7!

These release notes cover the *new features*, as well as some *backwards incompatible changes* you'll want to be aware of when upgrading from Django 1.6 or older versions. We've *begun the deprecation process for some features*, and some features have reached the end of their deprecation process and *have been removed*.

### Python compatibility

Django 1.7 requires Python 2.7, 3.2, 3.3, or 3.4. We **highly recommend** and only officially support the latest release of each series.

The Django 1.6 series is the last to support Python 2.6. Django 1.7 is the first release to support Python 3.4.

This change should affect only a small number of Django users, as most operating-system vendors today are shipping Python 2.7 or newer as their default version. If you're still using Python 2.6, however, you'll need to stick to Django 1.6 until you can upgrade your Python version. Per *our support policy*, Django 1.6 will continue to receive security support until the release of Django 1.8.

### What's new in Django 1.7

#### Schema migrations

Django now has built-in support for schema migrations. It allows models to be updated, changed, and deleted by creating migration files that represent the model changes and which can be run on any development, staging or production database.

Migrations are covered in *their own documentation*, but a few of the key features are:

- `syncdb` has been deprecated and replaced by `migrate`. Don't worry - calls to `syncdb` will still work as before.
- A new `makemigrations` command provides an easy way to autodetect changes to your models and make migrations for them.

`django.db.models.signals.pre_syncdb` and `django.db.models.signals.post_syncdb` have been deprecated, to be replaced by `pre_migrate` and `post_migrate` respectively. These new signals have slightly different arguments. Check the documentation for details.

- The `allow_syncdb` method on database routers is now called `allow_migrate`, but still performs the same function. Routers with `allow_syncdb` methods will still work, but that method name is deprecated and you should change it as soon as possible (nothing more than renaming is required).
- `initial_data` fixtures are no longer loaded for apps with migrations; if you want to load initial data for an app, we suggest you create a migration for your application and define a `RunPython` or `RunSQL` operation in the `operations` section of the migration.

- Test rollback behavior is different for apps with migrations; in particular, Django will no longer emulate roll-backs on non-transactional databases or inside `TransactionTestCase` *unless specifically requested*.
- It is not advised to have apps without migrations depend on (have a `ForeignKey` or `ManyToManyField` to) apps with migrations.

## App-loading refactor

Historically, Django applications were tightly linked to models. A singleton known as the “app cache” dealt with both installed applications and models. The `models` module was used as an identifier for applications in many APIs.

As the concept of *Django applications* matured, this code showed some shortcomings. It has been refactored into an “app registry” where `models` modules no longer have a central role and where it’s possible to attach configuration data to applications.

Improvements thus far include:

- Applications can run code at startup, before Django does anything else, with the `ready()` method of their configuration.
- Application labels are assigned correctly to models even when they’re defined outside of `models.py`. You don’t have to set `app_label` explicitly any more.
- It is possible to omit `models.py` entirely if an application doesn’t have any models.
- Applications can be relabeled with the `label` attribute of application configurations, to work around label conflicts.
- The name of applications can be customized in the admin with the `verbose_name` of application configurations.
- The admin automatically calls `autodiscover()` when Django starts. You can consequently remove this line from your `URLconf`.
- Django imports all application configurations and models as soon as it starts, through a deterministic and straightforward process. This should make it easier to diagnose import issues such as import loops.

## New method on Field subclasses

To help power both schema migrations and to enable easier addition of composite keys in future releases of Django, the `Field` API now has a new required method: `deconstruct()`.

This method takes no arguments, and returns a tuple of four items:

- `name`: The field’s attribute name on its parent model, or `None` if it is not part of a model
- `path`: A dotted, Python path to the class of this field, including the class name.
- `args`: Positional arguments, as a list
- `kwargs`: Keyword arguments, as a dict

These four values allow any field to be serialized into a file, as well as allowing the field to be copied safely, both essential parts of these new features.

This change should not affect you unless you write custom `Field` subclasses; if you do, you may need to reimplement the `deconstruct()` method if your subclass changes the method signature of `__init__` in any way. If your field just inherits from a built-in Django field and doesn’t override `__init__`, no changes are necessary.

If you do need to override `deconstruct()`, a good place to start is the built-in Django fields (`django/db/models/fields/__init__.py`) as several fields, including `DecimalField` and `DateField`, override it and show how to call the method on the superclass and simply add or remove extra arguments.

This also means that all arguments to fields must themselves be serializable; to see what we consider serializable, and to find out how to make your own classes serializable, read the [migration serialization documentation](#).

## Calling custom `QuerySet` methods from the `Manager`

Historically, the recommended way to make reusable model queries was to create methods on a custom `Manager` class. The problem with this approach was that after the first method call, you'd get back a `QuerySet` instance and couldn't call additional custom manager methods.

Though not documented, it was common to work around this issue by creating a custom `QuerySet` so that custom methods could be chained; but the solution had a number of drawbacks:

- The custom `QuerySet` and its custom methods were lost after the first call to `values()` or `values_list()`.
- Writing a custom `Manager` was still necessary to return the custom `QuerySet` class and all methods that were desired on the `Manager` had to be proxied to the `QuerySet`. The whole process went against the DRY principle.

The `QuerySet.as_manager()` class method can now directly *create `Manager` with `QuerySet` methods*:

```
class FoodQuerySet(models.QuerySet):
    def pizzas(self):
        return self.filter(kind='pizza')

    def vegetarian(self):
        return self.filter(vegetarian=True)

class Food(models.Model):
    kind = models.CharField(max_length=50)
    vegetarian = models.BooleanField(default=False)
    objects = FoodQuerySet.as_manager()

Food.objects.pizzas().vegetarian()
```

## Using a custom manager when traversing reverse relations

It is now possible to *specify a custom manager* when traversing a reverse relationship:

```
class Blog(models.Model):
    pass

class Entry(models.Model):
    blog = models.ForeignKey(Blog)

    objects = models.Manager() # Default Manager
    entries = EntryManager() # Custom Manager

b = Blog.objects.get(id=1)
b.entry_set(manager='entries').all()
```

## New system check framework

We've added a new *System check framework* for detecting common problems (like invalid models) and providing hints for resolving those problems. The framework is extensible so you can add your own checks for your own apps and libraries.

To perform system checks, you use the *check* management command. This command replaces the older *validate* management command.

## New `Prefetch` object for advanced `prefetch_related` operations.

The new *Prefetch* object allows customizing prefetch operations.

You can specify the `QuerySet` used to traverse a given relation or customize the storage location of prefetch results.

This enables things like filtering prefetched relations, calling `select_related()` from a prefetched relation, or prefetching the same relation multiple times with different querysets. See `prefetch_related()` for more details.

## Admin shortcuts support time zones

The “today” and “now” shortcuts next to date and time input widgets in the admin are now operating in the *current time zone*. Previously, they used the browser time zone, which could result in saving the wrong value when it didn't match the current time zone on the server.

In addition, the widgets now display a help message when the browser and server time zone are different, to clarify how the value inserted in the field will be interpreted.

## Using database cursors as context managers

Prior to Python 2.7, database cursors could be used as a context manager. The specific backend's cursor defined the behavior of the context manager. The behavior of magic method lookups was changed with Python 2.7 and cursors were no longer usable as context managers.

Django 1.7 allows a cursor to be used as a context manager. That is, the following can be used:

```
with connection.cursor() as c:
    c.execute(...)
```

instead of:

```
c = connection.cursor()
try:
    c.execute(...)
finally:
    c.close()
```

## Custom lookups

It is now possible to write custom lookups and transforms for the ORM. Custom lookups work just like Django's built-in lookups (e.g. `lte`, `icontains`) while transforms are a new concept.

The `django.db.models.Lookup` class provides a way to add lookup operators for model fields. As an example it is possible to add `day_lte` operator for `DateFields`.

The `django.db.models.Transform` class allows transformations of database values prior to the final lookup. For example it is possible to write a `year` transform that extracts year from the field's value. Transforms allow for chaining. After the `year` transform has been added to `DateTimeField` it is possible to filter on the transformed value, for example `qs.filter(author__birthdate__year__lte=1981)`.

For more information about both custom lookups and transforms refer to the [custom lookups](#) documentation.

## Improvements to Form error handling

### `Form.add_error()`

Previously there were two main patterns for handling errors in forms:

- Raising a `ValidationError` from within certain functions (e.g. `Field.clean()`, `Form.clean_<fieldname>()`, or `Form.clean()` for non-field errors.)
- Fiddling with `Form._errors` when targeting a specific field in `Form.clean()` or adding errors from outside of a “clean” method (e.g. directly from a view).

Using the former pattern was straightforward since the form can guess from the context (i.e. which method raised the exception) where the errors belong and automatically process them. This remains the canonical way of adding errors when possible. However the latter was fiddly and error-prone, since the burden of handling edge cases fell on the user.

The new `add_error()` method allows adding errors to specific form fields from anywhere without having to worry about the details such as creating instances of `django.forms.utils.ErrorList` or dealing with `Form.cleaned_data`. This new API replaces manipulating `Form._errors` which now becomes a private API.

See [Cleaning and validating fields that depend on each other](#) for an example using `Form.add_error()`.

### Error metadata

The `ValidationError` constructor accepts metadata such as `error_code` or `params` which are then available for interpolating into the error message (see [Raising ValidationError](#) for more details); however, before Django 1.7 those metadata were discarded as soon as the errors were added to `Form.errors`.

`Form.errors` and `django.forms.utils.ErrorList` now store the `ValidationError` instances so these metadata can be retrieved at any time through the new `Form.errors.as_data` method.

The retrieved `ValidationError` instances can then be identified thanks to their `error_code` which enables things like rewriting the error's message or writing custom logic in a view when a given error is present. It can also be used to serialize the errors in a custom format such as XML.

The new `Form.errors.as_json()` method is a convenience method which returns error messages along with error codes serialized as JSON. `as_json()` uses `as_data()` and gives an idea of how the new system could be extended.

### Error containers and backward compatibility

Heavy changes to the various error containers were necessary in order to support the features above, specifically `Form.errors`, `django.forms.utils.ErrorList`, and the internal storages of `ValidationError`. These containers which used to store error strings now store `ValidationError` instances and public APIs have been adapted to make this as transparent as possible, but if you've been using private APIs, some of the changes are backwards incompatible; see [ValidationError constructor and internal storage](#) for more details.

## Minor features

### `django.contrib.admin`

- You can now implement `site_header`, `site_title`, and `index_title` attributes on a custom `AdminSite` in order to easily change the admin site's page title and header text. No more needing to override templates!
- Buttons in `django.contrib.admin` now use the `border-radius` CSS property for rounded corners rather than GIF background images.
- Some admin templates now have `app-<app_name>` and `model-<model_name>` classes in their `<body>` tag to allow customizing the CSS per app or per model.
- The admin changelist cells now have a `field-<field_name>` class in the HTML to enable style customizations.
- The admin's search fields can now be customized per-request thanks to the new `django.contrib.admin.ModelAdmin.get_search_fields()` method.
- The `ModelAdmin.get_fields()` method may be overridden to customize the value of `ModelAdmin.fields`.
- In addition to the existing `admin.site.register` syntax, you can use the new `register()` decorator to register a `ModelAdmin`.
- You may specify `ModelAdmin.list_display_links = None` to disable links on the change list page grid.
- You may now specify `ModelAdmin.view_on_site` to control whether or not to display the "View on site" link.
- You can specify a descending ordering for a `ModelAdmin.list_display` value by prefixing the `admin_order_field` value with a hyphen.
- The `ModelAdmin.get_changeform_initial_data()` method may be overridden to define custom behavior for setting initial change form data.

### `django.contrib.auth`

- Any `**kwargs` passed to `email_user()` are passed to the underlying `send_mail()` call.
- The `permission_required()` decorator can take a list of permissions as well as a single permission.
- You can override the new `AuthenticationForm.confirm_login_allowed()` method to more easily customize the login policy.
- `django.contrib.auth.views.password_reset()` takes an optional `html_email_template_name` parameter used to send a multipart HTML email for password resets.
- The `AbstractBaseUser.get_session_auth_hash()` method was added and if your `AUTH_USER_MODEL` inherits from `AbstractBaseUser`, changing a user's password now invalidates old sessions if the `django.contrib.auth.middleware.SessionAuthenticationMiddleware` is enabled. See *Session invalidation on password change* for more details.

### `django.contrib.formtools`

- Calls to `WizardView.done()` now include a `form_dict` to allow easier access to forms by their step name.

### `django.contrib.gis`

- The default OpenLayers library version included in widgets has been updated from 2.11 to 2.13.
- Prepared geometries now also support the `crosses`, `disjoint`, `overlaps`, `touches` and `within` predicates, if GEOS 3.3 or later is installed.

### `django.contrib.messages`

- The backends for `django.contrib.messages` that use cookies, will now follow the `SESSION_COOKIE_SECURE` and `SESSION_COOKIE_HTTPONLY` settings.
- The `messages context processor` now adds a dictionary of default levels under the name `DEFAULT_MESSAGE_LEVELS`.
- `Message` objects now have a `level_tag` attribute that contains the string representation of the message level.

### `django.contrib.redirects`

- `RedirectFallbackMiddleware` has two new attributes (`response_gone_class` and `response_redirect_class`) that specify the types of `HttpResponse` instances the middleware returns.

### `django.contrib.sessions`

- The `"django.contrib.sessions.backends.cached_db"` session backend now respects `SESSION_CACHE_ALIAS`. In previous versions, it always used the *default* cache.

### `django.contrib.sitemaps`

- The `sitemap framework` now makes use of `lastmod` to set a Last-Modified header in the response. This makes it possible for the `ConditionalGetMiddleware` to handle conditional GET requests for sitemaps which set `lastmod`.

### `django.contrib.sites`

- The new `django.contrib.sites.middleware.CurrentSiteMiddleware` allows setting the current site on each request.

## `django.contrib.staticfiles`

- The *static files storage classes* may be subclassed to override the permissions that collected static files and directories receive by setting the *file\_permissions\_mode* and *directory\_permissions\_mode* parameters. See *collectstatic* for example usage.
- The `CachedStaticFilesStorage` backend gets a sibling class called `ManifestStaticFilesStorage` that doesn't use the cache system at all but instead a JSON file called `staticfiles.json` for storing the mapping between the original file name (e.g. `css/styles.css`) and the hashed file name (e.g. `css/styles.55e7cbb9ba48.css`). The `staticfiles.json` file is created when running the *collectstatic* management command and should be a less expensive alternative for remote storages such as Amazon S3.

See the `ManifestStaticFilesStorage` docs for more information.

- *findstatic* now accepts verbosity flag level 2, meaning it will show the relative paths of the directories it searched. See *findstatic* for example output.

## `django.contrib.syndication`

- The *Atom1Feed* syndication feed's `updated` element now utilizes `updateddate` instead of `pubdate`, allowing the published element to be included in the feed (which relies on `pubdate`).

## Cache

- Access to caches configured in *CACHES* is now available via `django.core.cache.caches`. This dict-like object provides a different instance per thread. It supersedes `django.core.cache.get_cache()` which is now deprecated.
- If you instantiate cache backends directly, be aware that they aren't thread-safe any more, as `django.core.cache.caches` now yields different instances per thread.
- Defining the *TIMEOUT* argument of the *CACHES* setting as `None` will set the cache keys as "non-expiring" by default. Previously, it was only possible to pass `timeout=None` to the cache backend's `set()` method.

## Cross Site Request Forgery

- The *CSRF\_COOKIE\_AGE* setting facilitates the use of session-based CSRF cookies.

## Email

- *send\_mail()* now accepts an `html_message` parameter for sending a multipart text/plain and text/html email.
- The SMTP *EmailBackend* now accepts a `timeout` parameter.

## File Storage

- File locking on Windows previously depended on the PyWin32 package; if it wasn't installed, file locking failed silently. That dependency has been removed, and file locking is now implemented natively on both Windows and Unix.

## File Uploads

- The new `UploadedFile.content_type_extra` attribute contains extra parameters passed to the `content-type` header on a file upload.
- The new `FILE_UPLOAD_DIRECTORY_PERMISSIONS` setting controls the file system permissions of directories created during file upload, like `FILE_UPLOAD_PERMISSIONS` does for the files themselves.
- The `FileField.upload_to` attribute is now optional. If it is omitted or given `None` or an empty string, a subdirectory won't be used for storing the uploaded files.
- Uploaded files are now explicitly closed before the response is delivered to the client. Partially uploaded files are also closed as long as they are named `file` in the upload handler.
- `Storage.get_available_name()` now appends an underscore plus a random 7 character alphanumeric string (e.g. `"_x3algho"`), rather than iterating through an underscore followed by a number (e.g. `"_1"`, `"_2"`, etc.) to prevent a denial-of-service attack. This change was also made in the 1.6.6, 1.5.9, and 1.4.14 security releases.

## Forms

- The `<label>` and `<input>` tags rendered by `RadioSelect` and `CheckboxSelectMultiple` when looping over the radio buttons or checkboxes now include `for` and `id` attributes, respectively. Each radio button or checkbox includes an `id_for_label` attribute to output the element's ID.
- The `<textarea>` tags rendered by `Textarea` now include a `maxlength` attribute if the `TextField` model field has a `max_length`.
- `Field.choices` now allows you to customize the “empty choice” label by including a tuple with an empty string or `None` for the key and the custom label as the value. The default blank option `"-----"` will be omitted in this case.
- `MultiValueField` allows optional subfields by setting the `require_all_fields` argument to `False`. The `required` attribute for each individual field will be respected, and a new `incomplete` validation error will be raised when any required fields are empty.
- The `clean()` method on a form no longer needs to return `self.cleaned_data`. If it does return a changed dictionary then that will still be used.
- After a temporary regression in Django 1.6, it's now possible again to make `TypedChoiceField` `coerce` method return an arbitrary value.
- `SelectDateWidget.months` can be used to customize the wording of the months displayed in the select widget.
- The `min_num` and `validate_min` parameters were added to `formset_factory()` to allow validating a minimum number of submitted forms.
- The metaclasses used by `Form` and `ModelForm` have been reworked to support more inheritance scenarios. The previous limitation that prevented inheriting from both `Form` and `ModelForm` simultaneously have been removed as long as `ModelForm` appears first in the MRO.
- It's now possible to remove a field from a `Form` when subclassing by setting the `name` to `None`.
- It's now possible to customize the error messages for `ModelForm`'s `unique`, `unique_for_date`, and `unique_together` constraints. In order to support `unique_together` or any other `NON_FIELD_ERROR`, `ModelForm` now looks for the `NON_FIELD_ERROR` key in the `error_messages` dictionary of the `ModelForm`'s inner `Meta` class. See *considerations regarding model's error\_messages* for more details.

## Internationalization

- The `django.middleware.locale.LocaleMiddleware.response_redirect_class` attribute allows you to customize the redirects issued by the middleware.
- The `LocaleMiddleware` now stores the user's selected language with the session key `_language`. This should only be accessed using the `LANGUAGE_SESSION_KEY` constant. Previously it was stored with the key `django_language` and the `LANGUAGE_SESSION_KEY` constant did not exist, but keys reserved for Django should start with an underscore. For backwards compatibility `django_language` is still read from in 1.7. Sessions will be migrated to the new key as they are written.
- The `blocktrans` tag now supports a `trimmed` option. This option will remove newline characters from the beginning and the end of the content of the `{% blocktrans %}` tag, replace any whitespace at the beginning and end of a line and merge all lines into one using a space character to separate them. This is quite useful for indenting the content of a `{% blocktrans %}` tag without having the indentation characters end up in the corresponding entry in the PO file, which makes the translation process easier.
- When you run `makemessages` from the root directory of your project, any extracted strings will now be automatically distributed to the proper app or project message file. See *Localization: how to create language files* for details.
- The `makemessages` command now always adds the `--previous` command line flag to the `msgmerge` command, keeping previously translated strings in po files for fuzzy strings.
- The following settings to adjust the language cookie options were introduced: `LANGUAGE_COOKIE_AGE`, `LANGUAGE_COOKIE_DOMAIN` and `LANGUAGE_COOKIE_PATH`.
- Added *Format localization* for Esperanto.

## Management Commands

- The new `--no-color` option for `django-admin` disables the colorization of management command output.
- The new `dumpdata --natural-foreign` and `dumpdata --natural-primary` options, and the new `use_natural_foreign_keys` and `use_natural_primary_keys` arguments for `serializers.serialize()`, allow the use of natural primary keys when serializing.
- It is no longer necessary to provide the cache table name or the `--database` option for the `createcachetable` command. Django takes this information from your settings file. If you have configured multiple caches or multiple databases, all cache tables are created.
- The `runserver` command received several improvements:
  - On Linux systems, if `pyinotify` is installed, the development server will reload immediately when a file is changed. Previously, it polled the filesystem for changes every second. That caused a small delay before reloads and reduced battery life on laptops.
  - In addition, the development server automatically reloads when a translation file is updated, i.e. after running `compilemessages`.
  - All HTTP requests are logged to the console, including requests for static files or `favicon.ico` that used to be filtered out.
- Management commands can now produce syntax colored output under Windows if the ANSICON third-party tool is installed and active.
- `collectstatic` command with `symlink` option is now supported on Windows NT 6 (Windows Vista and newer).

- Initial SQL data now works better if the `sqlparse` Python library is installed.

Note that it's deprecated in favor of the `RunSQL` operation of migrations, which benefits from the improved behavior.

## Models

- The `QuerySet.update_or_create()` method was added.
- The new `default_permissions` model Meta option allows you to customize (or disable) creation of the default add, change, and delete permissions.
- Explicit `OneToOneField` for *Multi-table inheritance* are now discovered in abstract classes.
- It is now possible to avoid creating a backward relation for `OneToOneField` by setting its `related_name` to '+' or ending it with '+ '.
- `F expressions` support the power operator (`**`).
- The `remove()` and `clear()` methods of the related managers created by `ForeignKey` and `GenericForeignKey` now accept the bulk keyword argument to control whether or not to perform operations in bulk (i.e. using `QuerySet.update()`). Defaults to `True`.
- It is now possible to use `None` as a query value for the `exact` lookup.
- It is now possible to pass a callable as value for the attribute `limit_choices_to` when defining a `ForeignKey` or `ManyToManyField`.
- Calling `only()` and `defer()` on the result of `QuerySet.values()` now raises an error (before that, it would either result in a database error or incorrect data).
- You can use a single list for `index_together` (rather than a list of lists) when specifying a single set of fields.
- Custom intermediate models having more than one foreign key to any of the models participating in a many-to-many relationship are now permitted, provided you explicitly specify which foreign keys should be used by setting the new `ManyToManyField.through_fields` argument.
- Assigning a model instance to a non-relation field will now throw an error. Previously this used to work if the field accepted integers as input as it took the primary key.
- Integer fields are now validated against database backend specific min and max values based on their `internal_type`. Previously model field validation didn't prevent values out of their associated column data type range from being saved resulting in an integrity error.
- It is now possible to explicitly `order_by()` a relation `_id` field by using its attribute name.

## Signals

- The `enter` argument was added to the `setting_changed` signal.
- The model signals can now be connected to using a `str` of the `'app_label.ModelName'` form – just like related fields – to lazily reference their senders.

## Templates

- The `Context.push()` method now returns a context manager which automatically calls `pop()` upon exiting the `with` statement. Additionally, `push()` now accepts parameters that are passed to the `dict` constructor used to build the new context level.

- The new `Context.flatten()` method returns a `Context`'s stack as one flat dictionary.
- `Context` objects can now be compared for equality (internally, this uses `Context.flatten()` so the internal structure of each `Context`'s stack doesn't matter as long as their flattened version is identical).
- The `widthratio` template tag now accepts an "as" parameter to capture the result in a variable.
- The `include` template tag will now also accept anything with a `render()` method (such as a `Template`) as an argument. String arguments will be looked up using `get_template()` as always.
- It is now possible to `include` templates recursively.
- Template objects now have an origin attribute set when `TEMPLATE_DEBUG` is `True`. This allows template origins to be inspected and logged outside of the `django.template` infrastructure.
- `TypeError` exceptions are no longer silenced when raised during the rendering of a template.
- The following functions now accept a `dirs` parameter which is a list or tuple to override `TEMPLATE_DIRS`:
  - `django.template.loader.get_template()`
  - `django.template.loader.select_template()`
  - `django.shortcuts.render()`
  - `django.shortcuts.render_to_response()`
- The `time` filter now accepts timezone-related *format specifiers* 'e', 'O', 'T' and 'Z' and is able to digest *time-zone-aware* `datetime` instances performing the expected rendering.
- The `cache` tag will now try to use the cache called "template\_fragments" if it exists and fall back to using the default cache otherwise. It also now accepts an optional `using` keyword argument to control which cache it uses.
- The new `truncatechars_html` filter truncates a string to be no longer than the specified number of characters, taking HTML into account.

## Requests and Responses

- The new `HttpRequest.scheme` attribute specifies the scheme of the request (`http` or `https` normally).
- The shortcut `redirect()` now supports relative URLs.
- The new `JsonResponse` subclass of `HttpResponse` helps easily create JSON-encoded responses.

## Tests

- `DiscoverRunner` has two new attributes, `test_suite` and `test_runner`, which facilitate overriding the way tests are collected and run.
- The `fetch_redirect_response` argument was added to `assertRedirects()`. Since the test client can't fetch external URLs, this allows you to use `assertRedirects` with redirects that aren't part of your Django app.
- Correct handling of scheme when making comparisons in `assertRedirects()`.
- The `secure` argument was added to all the request methods of `Client`. If `True`, the request will be made through HTTPS.
- `assertNumQueries()` now prints out the list of executed queries if the assertion fails.

- The `WSGIRequest` instance generated by the test handler is now attached to the `django.test.Response.wsgi_request` attribute.
- The database settings for testing have been collected into a dictionary named `TEST`.

## Utilities

- Improved `strip_tags()` accuracy (but it still cannot guarantee an HTML-safe result, as stated in the documentation).

## Validators

- `RegexValidator` now accepts the optional `flags` and Boolean `inverse_match` arguments. The `inverse_match` attribute determines if the `ValidationError` should be raised when the regular expression pattern matches (`True`) or does not match (`False`, by default) the provided `value`. The `flags` attribute sets the flags used when compiling a regular expression string.
- `URLValidator` now accepts an optional `schemes` argument which allows customization of the accepted URI schemes (instead of the defaults `http(s)` and `ftp(s)`).
- `validate_email()` now accepts addresses with IPv6 literals, like `example@[2001:db8::1]`, as specified in RFC 5321.

## Backwards incompatible changes in 1.7

**Warning:** In addition to the changes outlined in this section, be sure to review the [deprecation plan](#) for any features that have been removed. If you haven't updated your code within the deprecation timeline for a given feature, its removal may appear as a backwards incompatible change.

### `allow_syncdb / allow_migrate`

While Django will still look at `allow_syncdb` methods even though they should be renamed to `allow_migrate`, there is a subtle difference in which models get passed to these methods.

For apps with migrations, `allow_migrate` will now get passed *historical models*, which are special versioned models without custom attributes, methods or managers. Make sure your `allow_migrate` methods are only referring to fields or other items in `model._meta`.

### `initial_data`

Apps with migrations will not load `initial_data` fixtures when they have finished migrating. Apps without migrations will continue to load these fixtures during the phase of `migrate` which emulates the old `syncdb` behavior, but any new apps will not have this support.

Instead, you are encouraged to load initial data in migrations if you need it (using the `RunPython` operation and your model classes); this has the added advantage that your initial data will not need updating every time you change the schema.

Additionally, like the rest of Django's old `syncdb` code, `initial_data` has been started down the deprecation path and will be removed in Django 1.9.

## deconstruct() and serializability

Django now requires all Field classes and all of their constructor arguments to be serializable. If you modify the constructor signature in your custom Field in any way, you'll need to implement a `deconstruct()` method; we've expanded the custom field documentation with *instructions on implementing this method*.

The requirement for all field arguments to be *serializable* means that any custom class instances being passed into Field constructors - things like custom Storage subclasses, for instance - need to have a *deconstruct method defined on them as well*, though Django provides a handy class decorator that will work for most applications.

## App-loading changes

### Start-up sequence

Django 1.7 loads application configurations and models as soon as it starts. While this behavior is more straightforward and is believed to be more robust, regressions cannot be ruled out. See *Troubleshooting* for solutions to some problems you may encounter.

### Standalone scripts

If you're using Django in a plain Python script — rather than a management command — and you rely on the `DJANGO_SETTINGS_MODULE` environment variable, you must now explicitly initialize Django at the beginning of your script with:

```
>>> import django
>>> django.setup()
```

Otherwise, you will hit an `AppRegistryNotReady` exception.

### WSGI scripts

Until Django 1.3, the recommended way to create a WSGI application was:

```
import django.core.handlers.wsgi
application = django.core.handlers.wsgi.WSGIHandler()
```

In Django 1.4, support for WSGI was improved and the API changed to:

```
from django.core.wsgi import get_wsgi_application
application = get_wsgi_application()
```

If you're still using the former style in your WSGI script, you need to upgrade to the latter, or you will hit an `AppRegistryNotReady` exception.

### App registry consistency

It is no longer possible to have multiple installed applications with the same label. In previous versions of Django, this didn't always work correctly, but didn't crash outright either.

If you have two apps with the same label, you should create an `AppConfig` for one of them and override its `label` there. You should then adjust your code wherever it references this application or its models with the old label.

It isn't possible to import the same model twice through different paths any more. As of Django 1.6, this may happen only if you're manually putting a directory and a subdirectory on `PYTHONPATH`. Refer to the section on the new project layout in the *1.4 release notes* for migration instructions.

You should make sure that:

- All models are defined in applications that are listed in `INSTALLED_APPS` or have an explicit `app_label`.
- Models aren't imported as a side-effect of loading their application. Specifically, you shouldn't import models in the root module of an application nor in the module that define its configuration class.

Django will enforce these requirements as of version 1.9, after a deprecation period.

### Subclassing `AppCommand`

Subclasses of `AppCommand` must now implement a `handle_app_config()` method instead of `handle_app()`. This method receives an `AppConfig` instance instead of a models module.

### Introspecting applications

Since `INSTALLED_APPS` now supports application configuration classes in addition to application modules, you should review code that accesses this setting directly and use the app registry (`django.apps.apps`) instead.

The app registry has preserved some features of the old app cache. Even though the app cache was a private API, obsolete methods and arguments will be removed through a standard deprecation path, with the exception of the following changes that take effect immediately:

- `get_model` raises `LookupError` instead of returning `None` when no model is found.
- The `only_installed` argument of `get_model` and `get_models` no longer exists, nor does the `seed_cache` argument of `get_model`.

### Management commands and order of `INSTALLED_APPS`

When several applications provide management commands with the same name, Django loads the command from the application that comes first in `INSTALLED_APPS`. Previous versions loaded the command from the application that came last.

This brings discovery of management commands in line with other parts of Django that rely on the order of `INSTALLED_APPS`, such as static files, templates, and translations.

### `ValidationError` constructor and internal storage

The behavior of the `ValidationError` constructor has changed when it receives a container of errors as an argument (e.g. a list or an `ErrorList`):

- It converts any strings it finds to instances of `ValidationError` before adding them to its internal storage.
- It doesn't store the given container but rather copies its content to its own internal storage; previously the container itself was added to the `ValidationError` instance and used as internal storage.

This means that if you access the `ValidationError` internal storages, such as `error_list`; `error_dict`; or the return value of `update_error_dict()` you may find instances of `ValidationError` where you would have previously found strings.

Also if you directly assigned the return value of `update_error_dict()` to `Form._errors` you may inadvertently add *list* instances where `ErrorList` instances are expected. This is a problem because unlike a simple *list*, an `ErrorList` knows how to handle instances of `ValidationError`.

Most use-cases that warranted using these private APIs are now covered by the newly introduced `Form.add_error()` method:

```
# Old pattern:
try:
    # ...
except ValidationError as e:
    self._errors = e.update_error_dict(self._errors)

# New pattern:
try:
    # ...
except ValidationError as e:
    self.add_error(None, e)
```

If you need both Django <= 1.6 and 1.7 compatibility you can't use `Form.add_error()` since it wasn't available before Django 1.7, but you can use the following workaround to convert any *list* into `ErrorList`:

```
try:
    # ...
except ValidationError as e:
    self._errors = e.update_error_dict(self._errors)

# Additional code to ensure ``ErrorDict`` is exclusively
# composed of ``ErrorList`` instances.
for field, error_list in self._errors.items():
    if not isinstance(error_list, self.error_class):
        self._errors[field] = self.error_class(error_list)
```

## Behavior of `LocMemCache` regarding pickle errors

An inconsistency existed in previous versions of Django regarding how pickle errors are handled by different cache backends. `django.core.cache.backends.locmem.LocMemCache` used to fail silently when such an error occurs, which is inconsistent with other backends and leads to cache-specific errors. This has been fixed in Django 1.7, see #21200 for more details.

## Cache keys are now generated from the request's absolute URL

Previous versions of Django generated cache keys using a request's path and query string but not the scheme or host. If a Django application was serving multiple subdomains or domains, cache keys could collide. In Django 1.7, cache keys vary by the absolute URL of the request including scheme, host, path, and query string. For example, the URL portion of a cache key is now generated from `https://www.example.com/path/to/?key=val` rather than `/path/to/?key=val`. The cache keys generated by Django 1.7 will be different from the keys generated by older versions of Django. After upgrading to Django 1.7, the first request to any previously cached URL will be a cache miss.

## Passing None to Manager . db\_manager ()

In previous versions of Django, it was possible to use `db_manager(using=None)` on a model manager instance to obtain a manager instance using default routing behavior, overriding any manually specified database routing. In Django 1.7, a value of `None` passed to `db_manager` will produce a router that *retains* any manually assigned database routing – the manager will *not* be reset. This was necessary to resolve an inconsistency in the way routing information cascaded over joins. See [#13724](#) for more details.

## pytz may be required

If your project handles datetimes before 1970 or after 2037 and Django raises a `ValueError` when encountering them, you will have to install `pytz`. You may be affected by this problem if you use Django’s time zone-related date formats or `django.contrib.syndication`.

## remove () and clear () methods of related managers

The `remove ()` and `clear ()` methods of the related managers created by `ForeignKey`, `GenericForeignKey`, and `ManyToManyField` suffered from a number of issues. Some operations ran multiple data modifying queries without wrapping them in a transaction, and some operations didn’t respect default filtering when it was present (i.e. when the default manager on the related model implemented a custom `get_queryset ()`).

Fixing the issues introduced some backward incompatible changes:

- The default implementation of `remove ()` for `ForeignKey` related managers changed from a series of `Model.save ()` calls to a single `QuerySet.update ()` call. The change means that `pre_save` and `post_save` signals aren’t sent anymore. You can use the `bulk=False` keyword argument to revert to the previous behavior.
- The `remove ()` and `clear ()` methods for `GenericForeignKey` related managers now perform bulk delete. The `Model.delete ()` method isn’t called on each instance anymore. You can use the `bulk=False` keyword argument to revert to the previous behavior.
- The `remove ()` and `clear ()` methods for `ManyToManyField` related managers perform nested queries when filtering is involved, which may or may not be an issue depending on your database and your data itself. See [this note](#) for more details.

## Admin login redirection strategy

Historically, the Django admin site passed the request from an unauthorized or unauthenticated user directly to the login view, without HTTP redirection. In Django 1.7, this behavior changed to conform to a more traditional workflow where any unauthorized request to an admin page will be redirected (by HTTP status code 302) to the login page, with the `next` parameter set to the referring path. The user will be redirected there after a successful login.

Note also that the admin login form has been updated to not contain the `this_is_the_login_form` field (now unused) and the `ValidationError` code has been set to the more regular `invalid_login` key.

## select\_for\_update () requires a transaction

Historically, queries that use `select_for_update ()` could be executed in autocommit mode, outside of a transaction. Before Django 1.6, Django’s automatic transactions mode allowed this to be used to lock records until the next write operation. Django 1.6 introduced database-level autocommit; since then, execution in such a context voids the effect of `select_for_update ()`. It is, therefore, assumed now to be an error and raises an exception.

This change was made because such errors can be caused by including an app which expects global transactions (e.g. `ATOMIC_REQUESTS` set to `True`), or Django's old autocommit behavior, in a project which runs without them; and further, such errors may manifest as data-corruption bugs. It was also made in Django 1.6.3.

This change may cause test failures if you use `select_for_update()` in a test class which is a subclass of `TransactionTestCase` rather than `TestCase`.

### Contrib middleware removed from default `MIDDLEWARE_CLASSES`

The *app-loading refactor* deprecated using models from apps which are not part of the `INSTALLED_APPS` setting. This exposed an incompatibility between the default `INSTALLED_APPS` and `MIDDLEWARE_CLASSES` in the global defaults (`django.conf.global_settings`). To bring these settings in sync and prevent deprecation warnings when doing things like testing reusable apps with minimal settings, `SessionMiddleware`, `AuthenticationMiddleware`, and `MessageMiddleware` were removed from the defaults. These classes will still be included in the default settings generated by `startproject`. Most projects will not be affected by this change but if you were not previously declaring the `MIDDLEWARE_CLASSES` in your project settings and relying on the global default you should ensure that the new defaults are in line with your project's needs. You should also check for any code that accesses `django.conf.global_settings.MIDDLEWARE_CLASSES` directly.

### Miscellaneous

- The `django.core.files.uploadhandler.FileUploadHandler.new_file()` method is now passed an additional `content_type_extra` parameter. If you have a custom `FileUploadHandler` that implements `new_file()`, be sure it accepts this new parameter.
- `ModelFormSets` no longer delete instances when `save(commit=False)` is called. See `can_delete` for instructions on how to manually delete objects from deleted forms.
- Loading empty fixtures emits a `RuntimeWarning` rather than raising `CommandError`.
- `django.contrib.staticfiles.views.serve()` will now raise an `Http404` exception instead of `ImproperlyConfigured` when `DEBUG` is `False`. This change removes the need to conditionally add the view to your root URLconf, which in turn makes it safe to reverse by name. It also removes the ability for visitors to generate spurious HTTP 500 errors by requesting static files that don't exist or haven't been collected yet.
- The `django.db.models.Model.__eq__()` method is now defined in a way where instances of a proxy model and its base model are considered equal when primary keys match. Previously only instances of exact same class were considered equal on primary key match.
- The `django.db.models.Model.__eq__()` method has changed such that two `Model` instances without primary key values won't be considered equal (unless they are the same instance).
- The `django.db.models.Model.__hash__()` method will now raise `TypeError` when called on an instance without a primary key value. This is done to avoid mutable `__hash__` values in containers.
- `AutoField` columns in SQLite databases will now be created using the `AUTOINCREMENT` option, which guarantees monotonic increments. This will cause primary key numbering behavior to change on SQLite, becoming consistent with most other SQL databases. This will only apply to newly created tables. If you have a database created with an older version of Django, you will need to migrate it to take advantage of this feature. For example, you could do the following:
  1. Use `dumpdata` to save your data.
  2. Rename the existing database file (keep it as a backup).
  3. Run `migrate` to create the updated schema.

4. Use `loaddata` to import the fixtures you exported in (1).

- `django.contrib.auth.models.AbstractUser` no longer defines a `get_absolute_url()` method. The old definition returned `"/users/%s/" % urlquote(self.username)` which was arbitrary since applications may or may not define such a url in `urlpatterns`. Define a `get_absolute_url()` method on your own custom user object or use `ABSOLUTE_URL_OVERRIDES` if you want a URL for your user.
- The static asset-serving functionality of the `django.test.LiveServerTestCase` class has been simplified: Now it's only able to serve content already present in `STATIC_ROOT` when tests are run. The ability to transparently serve all the static assets (similarly to what one gets with `DEBUG = True` at development-time) has been moved to a new class that lives in the `staticfiles` application (the one actually in charge of such feature): `django.contrib.staticfiles.testing.StaticLiveServerTestCase`. In other words, `LiveServerTestCase` itself is less powerful but at the same time has less magic.

Rationale behind this is removal of dependency of non-contrib code on contrib applications.

- The old cache URI syntax (e.g. `"locmem://"`) is no longer supported. It still worked, even though it was not documented or officially supported. If you're still using it, please update to the current `CACHES` syntax.
- The default ordering of `Form` fields in case of inheritance has changed to follow normal Python MRO. Fields are now discovered by iterating through the MRO in reverse with the topmost class coming last. This only affects you if you relied on the default field ordering while having fields defined on both the current class *and* on a parent `Form`.
- The required argument of `SelectDateWidget` has been removed. This widget now respects the form field's `is_required` attribute like other widgets.
- `Widget.is_hidden` is now a read-only property, getting its value by introspecting the presence of `input_type == 'hidden'`.
- `select_related()` now chains in the same way as other similar calls like `prefetch_related`. That is, `select_related('foo', 'bar')` is equivalent to `select_related('foo').select_related('bar')`. Previously the latter would have been equivalent to `select_related('bar')`.
- GeoDjango dropped support for GEOS < 3.1.
- The `init_connection_state` method of database backends now executes in autocommit mode (unless you set `AUTOCOMMIT` to `False`). If you maintain a custom database backend, you should check that method.
- The `django.db.backends.BaseDatabaseFeatures.allows_primary_key_0` attribute has been renamed to `allows_auto_pk_0` to better describe it. It's `True` for all database backends included with Django except MySQL which does allow primary keys with value 0. It only forbids *autoincrement* primary keys with value 0.
- Shadowing model fields defined in a parent model has been forbidden as this creates ambiguity in the expected model behavior. In addition, clashing fields in the model inheritance hierarchy result in a system check error. For example, if you use multi-inheritance, you need to define custom primary key fields on parent models, otherwise the default `id` fields will clash. See [Multiple inheritance](#) for details.
- `django.utils.translation.parse_accept_lang_header()` now returns lowercase locales, instead of the case as it was provided. As locales should be treated case-insensitive this allows us to speed up locale detection.
- `django.utils.translation.get_language_from_path()` and `django.utils.translation.trans_real.get_supported_language_variant()` now no longer have a supported argument.
- The shortcut view in `django.contrib.contenttypes.views` now supports protocol-relative URLs (e.g. `//example.com`).

- `GenericRelation` now supports an optional `related_query_name` argument. Setting `related_query_name` adds a relation from the related object back to the content type for filtering, ordering and other query operations.
- When running tests on PostgreSQL, the `USER` will need read access to the built-in postgres database. This is in lieu of the previous behavior of connecting to the actual non-test database.
- As part of the *System check framework, fields, models, and model managers* all implement a `check()` method that is registered with the check framework. If you have an existing method called `check()` on one of these objects, you will need to rename it.
- As noted above in the “Cache” section of “Minor Features”, defining the `TIMEOUT` argument of the `CACHES` setting as `None` will set the cache keys as “non-expiring”. Previously, with the memcache backend, a `TIMEOUT` of 0 would set non-expiring keys, but this was inconsistent with the set-and-expire (i.e. no caching) behavior of `set("key", "value", timeout=0)`. If you want non-expiring keys, please update your settings to use `None` instead of 0 as the latter now designates set-and-expire in the settings as well.
- The `sql*` management commands now respect the `allow_migrate()` method of `DATABASE_ROUTERS`. If you have models synced to non-default databases, use the `--database` flag to get SQL for those models (previously they would always be included in the output).
- Decoding the query string from URLs now falls back to the ISO-8859-1 encoding when the input is not valid UTF-8.
- With the addition of the `django.contrib.auth.middleware.SessionAuthenticationMiddleware` to the default project template (pre-1.7.2 only), a database must be created before accessing a page using `runserver`.
- The addition of the `schemes` argument to `URLValidator` will appear as a backwards-incompatible change if you were previously using a custom regular expression to validate schemes. Any scheme not listed in `schemes` will fail validation, even if the regular expression matches the given URL.

## Features deprecated in 1.7

### `django.core.cache.get_cache`

`django.core.cache.get_cache` has been supplanted by `django.core.cache.caches`.

### `django.utils.dictconfig/django.utils.importlib`

`django.utils.dictconfig` and `django.utils.importlib` were copies of respectively `logging.config` and `importlib` provided for Python versions prior to 2.7. They have been deprecated.

### `django.utils.module_loading.import_by_path`

The current `django.utils.module_loading.import_by_path` function catches `AttributeError`, `ImportError`, and `ValueError` exceptions, and re-raises `ImproperlyConfigured`. Such exception masking makes it needlessly hard to diagnose circular import problems, because it makes it look like the problem comes from inside Django. It has been deprecated in favor of `import_string()`.

### `django.utils.tzinfo`

`django.utils.tzinfo` provided two `tzinfo` subclasses, `LocalTimezone` and `FixedOffset`. They've been deprecated in favor of more correct alternatives provided by `django.utils.timezone`, `django.utils.timezone.get_default_timezone()` and `django.utils.timezone.get_fixed_timezone()`.

### `django.utils.unittest`

`django.utils.unittest` provided uniform access to the `unittest2` library on all Python versions. Since `unittest2` became the standard library's `unittest` module in Python 2.7, and Django 1.7 drops support for older Python versions, this module isn't useful anymore. It has been deprecated. Use `unittest` instead.

### `django.utils.datastructures.SortedDict`

As `OrderedDict` was added to the standard library in Python 2.7, `SortedDict` is no longer needed and has been deprecated.

The two additional, deprecated methods provided by `SortedDict` (`insert()` and `value_for_index()`) have been removed. If you relied on these methods to alter structures like form fields, you should now treat these `OrderedDicts` as immutable objects and override them to change their content.

For example, you might want to override `MyFormClass.base_fields` (although this attribute isn't considered a public API) to change the ordering of fields for all `MyFormClass` instances; or similarly, you could override `self.fields` from inside `MyFormClass.__init__()`, to change the fields for a particular form instance. For example (from Django itself):

```
PasswordChangeForm.base_fields = OrderedDict(
    (k, PasswordChangeForm.base_fields[k])
    for k in ['old_password', 'new_password1', 'new_password2']
)
```

### Custom SQL location for models package

Previously, if models were organized in a package (`myapp/models/`) rather than simply `myapp/models.py`, Django would look for initial SQL data in `myapp/models/sql/`. This bug has been fixed so that Django will search `myapp/sql/` as documented. After this issue was fixed, migrations were added which deprecates initial SQL data. Thus, while this change still exists, the deprecation is irrelevant as the entire feature will be removed in Django 1.9.

### Reorganization of `django.contrib.sites`

`django.contrib.sites` provides reduced functionality when it isn't in `INSTALLED_APPS`. The app-loading refactor adds some constraints in that situation. As a consequence, two objects were moved, and the old locations are deprecated:

- `RequestSite` now lives in `django.contrib.sites.requests`.
- `get_current_site()` now lives in `django.contrib.sites.shortcuts`.

### declared\_fieldsets attribute on ModelAdmin

`ModelAdmin.declared_fieldsets` has been deprecated. Despite being a private API, it will go through a regular deprecation path. This attribute was mostly used by methods that bypassed `ModelAdmin.get_fieldsets()` but this was considered a bug and has been addressed.

### Reorganization of `django.contrib.contenttypes`

Since `django.contrib.contenttypes.generic` defined both admin and model related objects, an import of this module could trigger unexpected side effects. As a consequence, its contents were split into `contenttypes` submodules and the `django.contrib.contenttypes.generic` module is deprecated:

- `GenericForeignKey` and `GenericRelation` now live in `fields`.
- `BaseGenericInlineFormSet` and `generic_inlineformset_factory()` now live in `forms`.
- `GenericInlineModelAdmin`, `GenericStackedInline` and `GenericTabularInline` now live in `admin`.

### syncdb

The `syncdb` command has been deprecated in favor of the new `migrate` command. `migrate` takes the same arguments as `syncdb` used to plus a few more, so it's safe to just change the name you're calling and nothing else.

### util modules renamed to utils

The following instances of `util.py` in the Django codebase have been renamed to `utils.py` in an effort to unify all util and utils references:

- `django.contrib.admin.util`
- `django.contrib.gis.db.backends.util`
- `django.db.backends.util`
- `django.forms.util`

### get\_formsets method on ModelAdmin

`ModelAdmin.get_formsets` has been deprecated in favor of the new `get_formsets_with_inlines()`, in order to better handle the case of selectively showing inlines on a `ModelAdmin`.

### IPAddressField

The `django.db.models.IPAddressField` and `django.forms.IPAddressField` fields have been deprecated in favor of `django.db.models.GenericIPAddressField` and `django.forms.GenericIPAddressField`.

### **BaseMemcachedCache.\_get\_memcache\_timeout method**

The `BaseMemcachedCache._get_memcache_timeout()` method has been renamed to `get_backend_timeout()`. Despite being a private API, it will go through the normal deprecation.

### **Natural key serialization options**

The `--natural` and `-n` options for `dumpdata` have been deprecated. Use `dumpdata --natural-foreign` instead.

Similarly, the `use_natural_keys` argument for `serializers.serialize()` has been deprecated. Use `use_natural_foreign_keys` instead.

### **Merging of POST and GET arguments into WSGIRequest.REQUEST**

It was already strongly suggested that you use `GET` and `POST` instead of `REQUEST`, because the former are more explicit. The property `REQUEST` is deprecated and will be removed in Django 1.9.

### **django.utils.datastructures.MergeDict class**

`MergeDict` exists primarily to support merging `POST` and `GET` arguments into a `REQUEST` property on `WSGIRequest`. To merge dictionaries, use `dict.update()` instead. The class `MergeDict` is deprecated and will be removed in Django 1.9.

### **Language codes zh-cn, zh-tw and fy-nl**

The currently used language codes for Simplified Chinese `zh-cn`, Traditional Chinese `zh-tw` and (Western) Frysian `fy-nl` are deprecated and should be replaced by the language codes `zh-hans`, `zh-hant` and `fy` respectively. If you use these language codes, you should rename the locale directories and update your settings to reflect these changes. The deprecated language codes will be removed in Django 1.9.

### **django.utils.functional.memoize function**

The function `memoize` is deprecated and should be replaced by the `functools.lru_cache` decorator (available from Python 3.2 onwards).

Django ships a backport of this decorator for older Python versions and it's available at `django.utils.lru_cache.lru_cache`. The deprecated function will be removed in Django 1.9.

### **Geo Sitemaps**

Google has retired support for the Geo Sitemaps format. Hence Django support for Geo Sitemaps is deprecated and will be removed in Django 1.8.

## Passing callable arguments to queryset methods

Callable arguments for querysets were an undocumented feature that was unreliable. It's been deprecated and will be removed in Django 1.9.

Callable arguments were evaluated when a queryset was constructed rather than when it was evaluated, thus this feature didn't offer any benefit compared to evaluating arguments before passing them to queryset and created confusion that the arguments may have been evaluated at query time.

## ADMIN\_FOR setting

The ADMIN\_FOR feature, part of the admin docs, has been removed. You can remove the setting from your configuration at your convenience.

## SplitDateTimeWidget With DateTimeField

SplitDateTimeWidget support in *DateTimeField* is deprecated, use SplitDateTimeWidget with *SplitDateTimeField* instead.

## validate

The validate management command is deprecated in favor of the *check* command.

## django.core.management.BaseCommand

`requires_model_validation` is deprecated in favor of a new `requires_system_checks` flag. If the latter flag is missing, then the value of the former flag is used. Defining both `requires_system_checks` and `requires_model_validation` results in an error.

The `check()` method has replaced the old `validate()` method.

## ModelAdmin validators

The `ModelAdmin.validator_class` and `default_validator_class` attributes are deprecated in favor of the new `checks_class` attribute.

The `ModelAdmin.validate()` method is deprecated in favor of `ModelAdmin.check()`.

The `django.contrib.admin.validation` module is deprecated.

## django.db.backends.DatabaseValidation.validate\_field

This method is deprecated in favor of a new `check_field` method. The functionality required by `check_field()` is the same as that provided by `validate_field()`, but the output format is different. Third-party database backends needing this functionality should provide an implementation of `check_field()`.

## Loading ssi and url template tags from future library

Django 1.3 introduced `{% load ssi from future %}` and `{% load url from future %}` syntax for forward compatibility of the `ssi` and `url` template tags. This syntax is now deprecated and will be removed in Django 1.9. You can simply remove the `{% load ... from future %}` tags.

### `django.utils.text.javascript_quote`

`javascript_quote()` was an undocumented function present in `django.utils.text`. It was used internally in the `javascript_catalog view` whose implementation was changed to make use of `json.dumps()` instead. If you were relying on this function to provide safe output from untrusted strings, you should use `django.utils.html.escapejs` or the `escapejs` template filter. If all you need is to generate valid JavaScript strings, you can simply use `json.dumps()`.

### `fix_ampersands` utils method and template filter

The `django.utils.html.fix_ampersands` method and the `fix_ampersands` template filter are deprecated, as the escaping of ampersands is already taken care of by Django's standard HTML escaping features. Combining this with `fix_ampersands` would either result in double escaping, or, if the output is assumed to be safe, a risk of introducing XSS vulnerabilities. Along with `fix_ampersands`, `django.utils.html.clean_html` is deprecated, an undocumented function that calls `fix_ampersands`. As this is an accelerated deprecation, `fix_ampersands` and `clean_html` will be removed in Django 1.8.

## Reorganization of database test settings

All database settings with a `TEST_` prefix have been deprecated in favor of entries in a `TEST` dictionary in the database settings. The old settings will be supported until Django 1.9. For backwards compatibility with older versions of Django, you can define both versions of the settings as long as they match.

## FastCGI support

FastCGI support via the `runfcgi` management command will be removed in Django 1.9. Please deploy your project using WSGI.

### Moved objects in `contrib.sites`

Following the app-loading refactor, two objects in `django.contrib.sites.models` needed to be moved because they must be available without importing `django.contrib.sites.models` when `django.contrib.sites` isn't installed. Import `RequestSite` from `django.contrib.sites.requests` and `get_current_site()` from `django.contrib.sites.shortcuts`. The old import locations will work until Django 1.9.

### `django.forms.forms.get_declared_fields()`

Django no longer uses this functional internally. Even though it's a private API, it'll go through the normal deprecation cycle.

## Private Query Lookup APIs

Private APIs `django.db.models.sql.where.WhereNode.make_atom()` and `django.db.models.sql.where.Constraint` are deprecated in favor of the new *custom lookups API*.

## Features removed in 1.7

These features have reached the end of their deprecation cycle and are removed in Django 1.7. See *Features deprecated in 1.5* for details, including how to remove usage of these features.

- `django.utils.simplejson` is removed.
- `django.utils.itercompat.product` is removed.
- `INSTALLED_APPS` and `TEMPLATE_DIRS` are no longer corrected from a plain string into a tuple.
- `HttpResponse`, `SimpleTemplateResponse`, `TemplateResponse`, `render_to_response()`, `index()`, and `sitemap()` no longer take a `mimetype` argument
- `HttpResponse` immediately consumes its content if it's an iterator.
- The `AUTH_PROFILE_MODULE` setting, and the `get_profile()` method on the `User` model are removed.
- The `cleanup` management command is removed.
- The `daily_cleanup.py` script is removed.
- `select_related()` no longer has a `depth` keyword argument.
- The `get_warnings_state()/restore_warnings_state()` functions from `django.test.utils` and the `save_warnings_state()/restore_warnings_state()` `django.test.TestCase` are removed.
- The `check_for_test_cookie` method in `AuthenticationForm` is removed.
- The version of `django.contrib.auth.views.password_reset_confirm()` that supports base36 encoded user IDs (`django.contrib.auth.views.password_reset_confirm_uidb36`) is removed.
- The `django.utils.encoding.StrAndUnicode` mix-in is removed.

## 9.1.5 1.6 release

### Django 1.6.11 release notes

March 18, 2015

Django 1.6.11 fixes two security issues in 1.6.10.

### Denial-of-service possibility with `strip_tags()`

Last year `strip_tags()` was changed to work iteratively. The problem is that the size of the input it's processing can increase on each iteration which results in an infinite loop in `strip_tags()`. This issue only affects versions of Python that haven't received a [bugfix in HTMLParser](#); namely Python < 2.7.7 and 3.3.5. Some operating system vendors have also backported the fix for the Python bug into their packages of earlier versions.

To remedy this issue, `strip_tags()` will now return the original input if it detects the length of the string it's processing increases. Remember that absolutely NO guarantee is provided about the results of `strip_tags()`

being HTML safe. So NEVER mark safe the result of a `strip_tags()` call without escaping it first, for example with `escape()`.

### Mitigated possible XSS attack via user-supplied redirect URLs

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()` and `il8n`) to redirect the user to an “on success” URL. The security checks for these redirects (namely `django.utils.http.is_safe_url()`) accepted URLs with leading control characters and so considered URLs like `\x08javascript:... safe`. This issue doesn’t affect Django currently, since we only put this URL into the `Location` response header and browsers seem to ignore JavaScript there. Browsers we tested also treat URLs prefixed with control characters such as `%08//example.com` as relative paths so redirection to an unsafe target isn’t a problem either.

However, if a developer relies on `is_safe_url()` to provide safe redirect targets and puts such a URL into a link, they could suffer from an XSS attack as some browsers such as Google Chrome ignore control characters at the start of a URL in an anchor `href`.

### Django 1.6.10 release notes

January 13, 2015

Django 1.6.10 fixes several security issues in 1.6.9.

### WSGI header spoofing via underscore/dash conflation

When HTTP headers are placed into the WSGI environ, they are normalized by converting to uppercase, converting all dashes to underscores, and prepending `HTTP_`. For instance, a header `X-Auth-User` would become `HTTP_X_AUTH_USER` in the WSGI environ (and thus also in Django’s `request.META` dictionary).

Unfortunately, this means that the WSGI environ cannot distinguish between headers containing dashes and headers containing underscores: `X-Auth-User` and `X-Auth_User` both become `HTTP_X_AUTH_USER`. This means that if a header is used in a security-sensitive way (for instance, passing authentication information along from a front-end proxy), even if the proxy carefully strips any incoming value for `X-Auth-User`, an attacker may be able to provide an `X-Auth_User` header (with underscore) and bypass this protection.

In order to prevent such attacks, both Nginx and Apache 2.4+ strip all headers containing underscores from incoming requests by default. Django’s built-in development server now does the same. Django’s development server is not recommended for production use, but matching the behavior of common production servers reduces the surface area for behavior changes during deployment.

### Mitigated possible XSS attack via user-supplied redirect URLs

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()` and `il8n`) to redirect the user to an “on success” URL. The security checks for these redirects (namely `django.utils.http.is_safe_url()`) didn’t strip leading whitespace on the tested URL and as such considered URLs like `\njavascript:... safe`. If a developer relied on `is_safe_url()` to provide safe redirect targets and put such a URL into a link, they could suffer from a XSS attack. This bug doesn’t affect Django currently, since we only put this URL into the `Location` response header and browsers seem to ignore JavaScript there.

## Denial-of-service attack against `django.views.static.serve`

In older versions of Django, the `django.views.static.serve()` view read the files it served one line at a time. Therefore, a big file with no newlines would result in memory usage equal to the size of that file. An attacker could exploit this and launch a denial-of-service attack by simultaneously requesting many large files. This view now reads the file in chunks to prevent large memory usage.

Note, however, that this view has always carried a warning that it is not hardened for production use and should be used only as a development aid. Now may be a good time to audit your project and serve your files in production using a real front-end web server if you are not doing so.

## Database denial-of-service with `ModelMultipleChoiceField`

Given a form that uses `ModelMultipleChoiceField` and `show_hidden_initial=True` (not a documented API), it was possible for a user to cause an unreasonable number of SQL queries by submitting duplicate values for the field's data. The validation logic in `ModelMultipleChoiceField` now deduplicates submitted values to address this issue.

## Django 1.6.9 release notes

*January 2, 2015*

Django 1.6.9 fixes a regression in the 1.6.6 security release.

Additionally, Django's vendored version of six, `django.utils.six`, has been upgraded to the latest release (1.9.0).

### Bugfixes

- Fixed a regression with dynamically generated inlines and allowed field references in the admin (#23754).

## Django 1.6.8 release notes

*October 22, 2014*

Django 1.6.8 fixes a couple regressions in the 1.6.6 security release.

### Bugfixes

- Allowed related many-to-many fields to be referenced in the admin (#23604).
- Allowed inline and hidden references to admin fields (#23431).

## Django 1.6.7 release notes

*September 2, 2014*

Django 1.6.7 fixes several bugs in 1.6.6, including a regression related to a security fix in that release.

## Bugfixes

- Allowed inherited and m2m fields to be referenced in the admin (#23329).
- Fixed a crash when using `QuerySet.defer()` with `select_related()` (#23370).

## Django 1.6.6 release notes

August 20, 2014

Django 1.6.6 fixes several security issues and bugs in 1.6.5.

### `reverse()` could generate URLs pointing to other hosts

In certain situations, URL reversing could generate scheme-relative URLs (URLs starting with two slashes), which could unexpectedly redirect a user to a different host. An attacker could exploit this, for example, by redirecting users to a phishing site designed to ask for user’s passwords.

To remedy this, URL reversing now ensures that no URL starts with two slashes (`//`), replacing the second slash with its URL encoded counterpart (`%2F`). This approach ensures that semantics stay the same, while making the URL relative to the domain and not to the scheme.

### File upload denial-of-service

Before this release, Django’s file upload handling in its default configuration may degrade to producing a huge number of `os.stat()` system calls when a duplicate filename is uploaded. Since `stat()` may invoke IO, this may produce a huge data-dependent slowdown that slowly worsens over time. The net result is that given enough time, a user with the ability to upload files can cause poor performance in the upload handler, eventually causing it to become very slow simply by uploading 0-byte files. At this point, even a slow network connection and few HTTP requests would be all that is necessary to make a site unavailable.

We’ve remedied the issue by changing the algorithm for generating file names if a file with the uploaded name already exists. `Storage.get_available_name()` now appends an underscore plus a random 7 character alphanumeric string (e.g. `"_x3a1gho"`), rather than iterating through an underscore followed by a number (e.g. `"_1"`, `"_2"`, etc.).

### RemoteUserMiddleware session hijacking

When using the `RemoteUserMiddleware` and the `RemoteUserBackend`, a change to the `REMOTE_USER` header between requests without an intervening logout could result in the prior user’s session being co-opted by the subsequent user. The middleware now logs the user out on a failed login attempt.

### Data leakage via query string manipulation in `contrib.admin`

In older versions of Django it was possible to reveal any field’s data by modifying the “popup” and “to\_field” parameters of the query string on an admin change form page. For example, requesting a URL like `/admin/auth/user/?_popup=1&t=password` and viewing the page’s HTML allowed viewing the password hash of each user. While the admin requires users to have permissions to view the change form pages in the first place, this could leak data if you rely on users having access to view only certain fields on a model.

To address the issue, an exception will now be raised if a `to_field` value that isn’t a related field to a model that has been registered with the admin is specified.

## Bugfixes

- Corrected email and URL validation to reject a trailing dash (#22579).
- Prevented indexes on PostgreSQL virtual fields (#22514).
- Prevented edge case where values of FK fields could be initialized with a wrong value when an inline model formset is created for a relationship defined to point to a field other than the PK (#13794).
- Restored `pre_delete` signals for `GenericRelation` cascade deletion (#22998).
- Fixed transaction handling when specifying non-default database in `createcachetable` and `flush` (#23089).
- Fixed the “ORA-01843: not a valid month” errors when using Unicode with older versions of Oracle server (#20292).
- Restored bug fix for sending unicode email with Python 2.6.5 and below (#19107).
- Prevented `UnicodeDecodeError` in `runserver` with non-UTF-8 and non-English locale (#23265).
- Fixed JavaScript errors while editing multi-geometry objects in the OpenLayers widget (#23137, #23293).
- Prevented a crash on Python 3 with query strings containing unencoded non-ASCII characters (#22996).

## Django 1.6.5 release notes

May 14, 2014

Django 1.6.5 fixes two security issues and several bugs in 1.6.4.

### Issue: Caches may incorrectly be allowed to store and serve private data

In certain situations, Django may allow caches to store private data related to a particular session and then serve that data to requests with a different session, or no session at all. This can lead to information disclosure and can be a vector for cache poisoning.

When using Django sessions, Django will set a `Vary: Cookie` header to ensure caches do not serve cached data to requests from other sessions. However, older versions of Internet Explorer (most likely only Internet Explorer 6, and Internet Explorer 7 if run on Windows XP or Windows Server 2003) are unable to handle the `Vary` header in combination with many content types. Therefore, Django would remove the header if the request was made by Internet Explorer.

To remedy this, the special behavior for these older Internet Explorer versions has been removed, and the `Vary` header is no longer stripped from the response. In addition, modifications to the `Cache-Control` header for all Internet Explorer requests with a `Content-Disposition` header have also been removed as they were found to have similar issues.

### Issue: Malformed redirect URLs from user input not correctly validated

The validation for redirects did not correctly validate some malformed URLs, which are accepted by some browsers. This allows a user to be redirected to an unsafe URL unexpectedly.

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()`, `django.contrib.comments`, and `i18n`) to redirect the user to an “on success” URL. The security checks for these redirects (namely `django.utils.http.is_safe_url()`) did not correctly validate some malformed URLs, such as `http://\djantoproject.com`, which are accepted by some browsers with more liberal URL parsing.

To remedy this, the validation in `is_safe_url()` has been tightened to be able to handle and correctly validate these malformed URLs.

### Bugfixes

- Made the `year_lookup_bounds_for_datetime_field` Oracle backend method Python 3 compatible (#22551).
- Fixed `pgettext_lazy` crash when receiving bytestring content on Python 2 (#22565).
- Fixed the SQL generated when filtering by a negated `Q` object that contains a `F` object. (#22429).
- Avoided overwriting data fetched by `select_related()` in certain cases which could cause minor performance regressions (#22508).

### Django 1.6.4 release notes

April 28, 2014

Django 1.6.4 fixes several bugs in 1.6.3.

### Bugfixes

- Added backwards compatibility support for the `django.contrib.messages` cookie format of Django 1.4 and earlier to facilitate upgrading to 1.6 from 1.4 (#22426).
- Restored the ability to `reverse()` views created using `functools.partial()` (#22486).
- Fixed the `object_id` of the `LogEntry` that's created after a user password change in the admin (#22515).

### Django 1.6.3 release notes

April 21, 2014

Django 1.6.3 fixes several bugs in 1.6.2, including three security issues, and makes one backwards-incompatible change:

#### Unexpected code execution using `reverse()`

Django's URL handling is based on a mapping of regex patterns (representing the URLs) to callable views, and Django's own processing consists of matching a requested URL against those patterns to determine the appropriate view to invoke.

Django also provides a convenience function – `reverse()` – which performs this process in the opposite direction. The `reverse()` function takes information about a view and returns a URL which would invoke that view. Use of `reverse()` is encouraged for application developers, as the output of `reverse()` is always based on the current URL patterns, meaning developers do not need to change other code when making changes to URLs.

One argument signature for `reverse()` is to pass a dotted Python path to the desired view. In this situation, Django will import the module indicated by that dotted path as part of generating the resulting URL. If such a module has import-time side effects, those side effects will occur.

Thus it is possible for an attacker to cause unexpected code execution, given the following conditions:

1. One or more views are present which construct a URL based on user input (commonly, a “next” parameter in a querystring indicating where to redirect upon successful completion of an action).
2. One or more modules are known to an attacker to exist on the server’s Python import path, which perform code execution with side effects on importing.

To remedy this, `reverse()` will now only accept and import dotted paths based on the view-containing modules listed in the project’s *URL pattern configuration*, so as to ensure that only modules the developer intended to be imported in this fashion can or will be imported.

## Caching of anonymous pages could reveal CSRF token

Django includes both a *caching framework* and a system for *preventing cross-site request forgery (CSRF) attacks*. The CSRF-protection system is based on a random nonce sent to the client in a cookie which must be sent by the client on future requests and, in forms, a hidden value which must be submitted back with the form.

The caching framework includes an option to cache responses to anonymous (i.e., unauthenticated) clients.

When the first anonymous request to a given page is by a client which did not have a CSRF cookie, the cache framework will also cache the CSRF cookie and serve the same nonce to other anonymous clients who do not have a CSRF cookie. This can allow an attacker to obtain a valid CSRF cookie value and perform attacks which bypass the check for the cookie.

To remedy this, the caching framework will no longer cache such responses. The heuristic for this will be:

1. If the incoming request did not submit any cookies, and
2. If the response did send one or more cookies, and
3. If the `Vary: Cookie` header is set on the response, then the response will not be cached.

## MySQL typecasting

The MySQL database is known to “typecast” on certain queries; for example, when querying a table which contains string values, but using a query which filters based on an integer value, MySQL will first silently coerce the strings to integers and return a result based on that.

If a query is performed without first converting values to the appropriate type, this can produce unexpected results, similar to what would occur if the query itself had been manipulated.

Django’s model field classes are aware of their own types and most such classes perform explicit conversion of query arguments to the correct database-level type before querying. However, three model field classes did not correctly convert their arguments:

- `FilePathField`
- `GenericIPAddressField`
- `IPAddressField`

These three fields have been updated to convert their arguments to the correct types before querying.

Additionally, developers of custom model fields are now warned via documentation to ensure their custom field classes will perform appropriate type conversions, and users of the `raw()` and `extra()` query methods – which allow the developer to supply raw SQL or SQL fragments – will be advised to ensure they perform appropriate manual type conversions prior to executing queries.

### `select_for_update()` requires a transaction

Historically, queries that use `select_for_update()` could be executed in autocommit mode, outside of a transaction. Before Django 1.6, Django's automatic transactions mode allowed this to be used to lock records until the next write operation. Django 1.6 introduced database-level autocommit; since then, execution in such a context voids the effect of `select_for_update()`. It is, therefore, assumed now to be an error and raises an exception.

This change was made because such errors can be caused by including an app which expects global transactions (e.g. `ATOMIC_REQUESTS` set to `True`), or Django's old autocommit behavior, in a project which runs without them; and further, such errors may manifest as data-corruption bugs.

This change may cause test failures if you use `select_for_update()` in a test class which is a subclass of `TransactionTestCase` rather than `TestCase`.

### Other bugfixes and changes

- Content retrieved from the GeoIP library is now properly decoded from its default `iso-8859-1` encoding (#21996).
- Fixed `AttributeError` when using `bulk_create()` with `ForeignKey` (#21566).
- Fixed crash of `QuerySets` that use `F()` + `timedelta()` when their query was compiled more once (#21643).
- Prevented custom widget class attribute of `IntegerField` subclasses from being overwritten by the code in their `__init__` method (#22245).
- Improved `strip_tags()` accuracy (but it still cannot guarantee an HTML-safe result, as stated in the documentation).
- Fixed a regression in the `django.contrib.gis` SQL compiler for non-concrete fields (#22250).
- Fixed `ModelAdmin.preserve_filters` when running a site with a URL prefix (#21795).
- Fixed a crash in the `find_command` management utility when the `PATH` environment variable wasn't set (#22256).
- Fixed `changepassword` on Windows (#22364).
- Avoided shadowing deadlock exceptions on MySQL (#22291).
- Wrapped database exceptions in `_set_autocommit` (#22321).
- Fixed atomicity when closing a database connection or when the database server disconnects (#21239 and #21202)
- Fixed regression in `prefetch_related` that caused the related objects query to include an unnecessary join (#21760).

Additionally, Django's vendored version of `six`, `django.utils.six` has been upgraded to the latest release (1.6.1).

### Django 1.6.2 release notes

February 6, 2014

This is Django 1.6.2, a bugfix release for Django 1.6. Django 1.6.2 fixes several bugs in 1.6.1:

- Prevented the base geometry object of a prepared geometry to be garbage collected, which could lead to crash Django (#21662).

- Fixed a crash when executing the `changepassword` command when the user object representation contained non-ASCII characters (#21627).
- The `collectstatic` command will raise an error rather than default to using the current working directory if `STATIC_ROOT` is not set. Combined with the `--clear` option, the previous behavior could wipe anything below the current working directory (#21581).
- Fixed mail encoding on Python 3.3.3+ (#21093).
- Fixed an issue where when `settings.DATABASES['default']['AUTOCOMMIT'] = False`, the connection wasn't in autocommit mode but Django pretended it was.
- Fixed a regression in multiple-table inheritance `exclude()` queries (#21787).
- Added missing items to `django.utils.timezone.__all__` (#21880).
- Fixed a field misalignment issue with `select_related()` and model inheritance (#21413).
- Fixed join promotion for negated AND conditions (#21748).
- Oracle database introspection now works with boolean and float fields (#19884).
- Fixed an issue where lazy objects weren't actually marked as safe when passed through `mark_safe()` and could end up being double-escaped (#21882).

Additionally, Django's vendored version of six, `django.utils.six` has been upgraded to the latest release (1.5.2).

## Django 1.6.1 release notes

December 12, 2013

This is Django 1.6.1, a bugfix release for Django 1.6. In addition to the bug fixes listed below, translations submitted since the 1.6 release are also included.

### Bug fixes

- Fixed `BCryptSHA256PasswordHasher` with `py-bcrypt` and Python 3 (#21398).
- Fixed a regression that prevented a `ForeignKey` with a hidden reverse manager (`related_name` ending with '+') from being used as a lookup for `prefetch_related` (#21410).
- Fixed `Queryset.datetimes` raising `AttributeError` in some situations (#21432).
- Fixed `ModelBackend` raising `UnboundLocalError` if `get_user_model()` raised an error (#21439).
- Fixed a regression that prevented editable `GenericRelation` subclasses from working in `ModelForms` (#21428).
- Added missing `to_python` method for `ModelMultipleChoiceField` which is required in Django 1.6 to properly detect changes from initial values (#21568).
- Fixed `django.contrib.humanize` translations where the unicode sequence for the non-breaking space was returned verbatim (#21415).
- Fixed `loaddata` error when fixture file name contained any dots not related to file extensions (#21457) or when fixture path was relative but located in a subdirectory (#21551).
- Fixed display of inline instances in formsets when parent has 0 for primary key (#21472).
- Fixed a regression where custom queriesets for foreign keys were overwritten if `ModelAdmin` had `ordering` set (#21405).

- Removed mention of a feature in the `--locale/-l` option of the `makemessages` and `compilemessages` commands that never worked as promised: Support of multiple locale names separated by commas. It's still possible to specify multiple locales in one run by using the option multiple times (#21488, #17181).
- Fixed a regression that unnecessarily triggered settings configuration when importing `get_wsgi_application` (#21486).
- Fixed test client `logout()` method when using the cookie-based session backend (#21448).
- Fixed a crash when a `GeometryField` uses a non-geometric widget (#21496).
- Fixed password hash upgrade when changing the iteration count (#21535).
- Fixed a bug in the debug view when the `URLconf` only contains one element (#21530).
- Re-added missing search result count and reset link in changelist admin view (#21510).
- The current language is no longer saved to the session by `LocaleMiddleware` on every response, but rather only after a logout (#21473).
- Fixed a crash when executing `runserver` on non-English systems and when the formatted date in its output contained non-ASCII characters (#21358).
- Fixed a crash in the debug view after an exception occurred on Python  $\geq 3.3$  (#21443).
- Fixed a crash in `ImageField` on some platforms (Homebrew and RHEL6 reported) (#21355).
- Fixed a regression when using generic relations in `ModelAdmin.list_filter` (#21431).

## Django 1.6 release notes

---

**Note:** Dedicated to Malcolm Tredinnick

On March 17, 2013, the Django project and the free software community lost a very dear friend and developer.

Malcolm was a long-time contributor to Django, a model community member, a brilliant mind, and a friend. His contributions to Django — and to many other open source projects — are nearly impossible to enumerate. Many on the core Django team had their first patches reviewed by him; his mentorship enriched us. His consideration, patience, and dedication will always be an inspiration to us.

This release of Django is for Malcolm.

– The Django Developers

---

*November 6, 2013*

Welcome to Django 1.6!

These release notes cover the *new features*, as well as some *backwards incompatible changes* you'll want to be aware of when upgrading from Django 1.5 or older versions. We've also dropped some features, which are detailed in *our deprecation plan*, and we've *begun the deprecation process for some features*.

## Python compatibility

Django 1.6, like Django 1.5, requires Python 2.6.5 or above. Python 3 is also officially supported. We **highly recommend** the latest minor release for each supported Python series (2.6.X, 2.7.X, 3.2.X, and 3.3.X).

Django 1.6 will be the final release series to support Python 2.6; beginning with Django 1.7, the minimum supported Python version will be 2.7.

Python 3.4 is not supported, but support will be added in Django 1.7.

## What's new in Django 1.6

### Simplified default project and app templates

The default templates used by `startproject` and `startapp` have been simplified and modernized. The `admin` is now enabled by default in new projects; the `sites` framework no longer is. `clickjacking prevention` is now on and the database defaults to SQLite.

If the default templates don't suit your tastes, you can use *custom project and app templates*.

### Improved transaction management

Django's transaction management was overhauled. Database-level autocommit is now turned on by default. This makes transaction handling more explicit and should improve performance. The existing APIs were deprecated, and new APIs were introduced, as described in the *transaction management docs*.

### Persistent database connections

Django now supports reusing the same database connection for several requests. This avoids the overhead of re-establishing a connection at the beginning of each request. For backwards compatibility, this feature is disabled by default. See *Persistent connections* for details.

### Discovery of tests in any test module

Django 1.6 ships with a new test runner that allows more flexibility in the location of tests. The previous runner (`django.test.simple.DjangoTestSuiteRunner`) found tests only in the `models.py` and `tests.py` modules of a Python package in `INSTALLED_APPS`.

The new runner (`django.test.runner.DiscoverRunner`) uses the test discovery features built into `unittest2` (the version of `unittest` in the Python 2.7+ standard library, and bundled with Django). With test discovery, tests can be located in any module whose name matches the pattern `test*.py`.

In addition, the test labels provided to `./manage.py test` to nominate specific tests to run must now be full Python dotted paths (or directory paths), rather than `applabel.TestCase.test_method_name` pseudo-paths. This allows running tests located anywhere in your codebase, rather than only in `INSTALLED_APPS`. For more details, see *Testing in Django*.

This change is backwards-incompatible; see the *backwards-incompatibility notes*.

### Time zone aware aggregation

The support for *time zones* introduced in Django 1.4 didn't work well with `QuerySet.dates()`: aggregation was always performed in UTC. This limitation was lifted in Django 1.6. Use `QuerySet.datetimes()` to perform time zone aware aggregation on a `DateTimeField`.

### Support for savepoints in SQLite

Django 1.6 adds support for savepoints in SQLite, with some *limitations*.

## BinaryField model field

A new `django.db.models.BinaryField` model field allows storage of raw binary data in the database.

## GeoDjango form widgets

GeoDjango now provides *form fields and widgets* for its geo-specialized fields. They are OpenLayers-based by default, but they can be customized to use any other JS framework.

## check management command added for verifying compatibility

A *check* management command was added, enabling you to verify if your current configuration (currently oriented at settings) is compatible with the current version of Django.

## Model.save() algorithm changed

The `Model.save()` method now tries to directly UPDATE the database if the instance has a primary key value. Previously SELECT was performed to determine if UPDATE or INSERT were needed. The new algorithm needs only one query for updating an existing row while the old algorithm needed two. See `Model.save()` for more details.

In some rare cases the database doesn't report that a matching row was found when doing an UPDATE. An example is the PostgreSQL ON UPDATE trigger which returns NULL. In such cases it is possible to set `django.db.models.Options.select_on_save` flag to force saving to use the old algorithm.

## Minor features

- Authentication backends can raise `PermissionDenied` to immediately fail the authentication chain.
- The `HttpOnly` flag can be set on the CSRF cookie with `CSRF_COOKIE_HTTPONLY`.
- The `assertQuerysetEqual()` now checks for undefined order and raises `ValueError` if undefined order is spotted. The order is seen as undefined if the given `QuerySet` isn't ordered and there are more than one ordered values to compare against.
- Added `earliest()` for symmetry with `latest()`.
- In addition to `year`, `month` and `day`, the ORM now supports `hour`, `minute` and `second` lookups.
- Django now wraps all PEP-249 exceptions.
- The default widgets for `EmailField`, `URLField`, `IntegerField`, `FloatField` and `DecimalField` use the new type attributes available in HTML5 (`type='email'`, `type='url'`, `type='number'`). Note that due to erratic support of the `number` input type with localized numbers in current browsers, Django only uses it when numeric fields are not localized.
- The `number` argument for *lazy plural translations* can be provided at translation time rather than at definition time.
- For custom management commands: Verification of the presence of valid settings in commands that ask for it by using the `can_import_settings` internal option is now performed independently from handling of the locale that should be active during the execution of the command. The latter can now be influenced by the new `leave_locale_alone` internal option. See *Management commands and locales* for more details.
- The `success_url` of `DeletionMixin` is now interpolated with its object's `__dict__`.

- `HttpResponseRedirect` and `HttpResponsePermanentRedirect` now provide an `url` attribute (equivalent to the URL the response will redirect to).
- The `MemcachedCache` cache backend now uses the latest `pickle` protocol available.
- Added `SuccessMessageMixin` which provides a `success_message` attribute for `FormView` based classes.
- Added the `django.db.models.ForeignKey.db_constraint` and `django.db.models.ManyToManyField.db_constraint` options.
- The jQuery library embedded in the admin has been upgraded to version 1.9.1.
- Syndication feeds (`django.contrib.syndication`) can now pass extra context through to feed templates using a new `Feed.get_context_data()` callback.
- The admin list columns have a `column-<field_name>` class in the HTML so the columns header can be styled with CSS, e.g. to set a column width.
- The `isolation level` can be customized under PostgreSQL.
- The `blocktrans` template tag now respects `TEMPLATE_STRING_IF_INVALID` for variables not present in the context, just like other template constructs.
- `SimpleLazyObjects` will now present more helpful representations in shell debugging situations.
- Generic `GeometryField` is now editable with the `OpenLayers` widget in the admin.
- The documentation contains a *deployment checklist*.
- The `diffsettings` command gained a `--all` option.
- `django.forms.fields.Field.__init__` now calls `super()`, allowing field mixins to implement `__init__()` methods that will reliably be called.
- The `validate_max` parameter was added to `BaseFormSet` and `formset_factory()`, and `ModelForm` and inline versions of the same. The behavior of validation for formsets with `max_num` was clarified. The previously undocumented behavior that hardened formsets against memory exhaustion attacks was documented, and the undocumented limit of the higher of 1000 or `max_num` forms was changed so it is always 1000 more than `max_num`.
- Added `BCryptSHA256PasswordHasher` to resolve the password truncation issue with `bcrypt`.
- `Pillow` is now the preferred image manipulation library to use with Django. `PIL` is pending deprecation (support to be removed in Django 1.8). To upgrade, you should **first** uninstall `PIL`, **then** install `Pillow`.
- `ModelForm` accepts several new `Meta` options.
  - Fields included in the `localized_fields` list will be localized (by setting `localize` on the form field).
  - The `labels`, `help_texts` and `error_messages` options may be used to customize the default fields, see *Overriding the default fields* for details.
- The `choices` argument to model fields now accepts an iterable of iterables instead of requiring an iterable of lists or tuples.
- The reason phrase can be customized in HTTP responses using `reason_phrase`.
- When giving the URL of the next page for `logout()`, `password_reset()`, `password_reset_confirm()`, and `password_change()`, you can now pass URL names and they will be resolved.
- The new `dumpdata --pks` option specifies the primary keys of objects to dump. This option can only be used with one model.

- Added `QuerySet` methods `first()` and `last()` which are convenience methods returning the first or last object matching the filters. Returns `None` if there are no objects matching.
- `View` and `RedirectView` now support HTTP PATCH method.
- `GenericForeignKey` now takes an optional `for_concrete_model` argument, which when set to `False` allows the field to reference proxy models. The default is `True` to retain the old behavior.
- The `LocaleMiddleware` now stores the active language in session if it is not present there. This prevents loss of language settings after session flush, e.g. logout.
- `SuspiciousOperation` has been differentiated into a number of subclasses, and each will log to a matching named logger under the `django.security` logging hierarchy. Along with this change, a `handler400` mechanism and default view are used whenever a `SuspiciousOperation` reaches the WSGI handler to return an `HttpResponseBadRequest`.
- The `DoesNotExist` exception now includes a message indicating the name of the attribute used for the lookup.
- The `get_or_create()` method no longer requires at least one keyword argument.
- The `SimpleTestCase` class includes a new assertion helper for testing formset errors: `assertFormsetError()`.
- The list of related fields added to a `QuerySet` by `select_related()` can be cleared using `select_related(None)`.
- The `get_extra()` and `get_max_num()` methods on `InlineModelAdmin` may be overridden to customize the extra and maximum number of inline forms.
- Formsets now have a `total_error_count()` method.
- `ModelForm` fields can now override error messages defined in model fields by using the `error_messages` argument of a `Field`'s constructor. To take advantage of this new feature with your custom fields, *see the updated recommendation* for raising a `ValidationError`.
- `ModelAdmin` now preserves filters on the list view after creating, editing or deleting an object. It's possible to restore the previous behavior of clearing filters by setting the `preserve_filters` attribute to `False`.
- Added `FormMixin.get_prefix()` (which returns `FormMixin.prefix` by default) to allow customizing the `prefix` of the form.
- Raw queries (`Manager.raw()` or `cursor.execute()`) can now use the “pyformat” parameter style, where placeholders in the query are given as `'%(name)s'` and the parameters are passed as a dictionary rather than a list (except on SQLite). This has long been possible (but not officially supported) on MySQL and PostgreSQL, and is now also available on Oracle.
- The default iteration count for the PBKDF2 password hasher has been increased by 20%. This backwards compatible change will not affect existing passwords or users who have subclassed `django.contrib.auth.hashers.PBKDF2PasswordHasher` to change the default value. Passwords *will be upgraded* to use the new iteration count as necessary.

## Backwards incompatible changes in 1.6

<p><b>Warning:</b> In addition to the changes outlined in this section, be sure to review the <i>deprecation plan</i> for any features that have been removed. If you haven't updated your code within the deprecation timeline for a given feature, its removal may appear as a backwards incompatible change.</p>
---

## New transaction management model

### Behavior changes

Database-level autocommit is enabled by default in Django 1.6. While this doesn't change the general spirit of Django's transaction management, there are a few backwards-incompatibilities.

### Savepoints and `assertNumQueries`

The changes in transaction management may result in additional statements to create, release or rollback savepoints. This is more likely to happen with SQLite, since it didn't support savepoints until this release.

If tests using `assertNumQueries()` fail because of a higher number of queries than expected, check that the extra queries are related to savepoints, and adjust the expected number of queries accordingly.

### Autocommit option for PostgreSQL

In previous versions, database-level autocommit was only an option for PostgreSQL, and it was disabled by default. This option is now ignored and can be removed.

### New test runner

In order to maintain greater consistency with Python's `unittest` module, the new test runner (`django.test.runner.DiscoverRunner`) does not automatically support some types of tests that were supported by the previous runner:

- Tests in `models.py` and `tests/__init__.py` files will no longer be found and run. Move them to a file whose name begins with `test`.
- Doctests will no longer be automatically discovered. To integrate doctests in your test suite, follow the [recommendations in the Python documentation](#).

Django bundles a modified version of the `doctest` module from the Python standard library (in `django.test._doctest`) and includes some additional doctest utilities. These utilities are deprecated and will be removed in Django 1.8; doctest suites should be updated to work with the standard library's doctest module (or converted to `unittest`-compatible tests).

If you wish to delay updates to your test suite, you can set your `TEST_RUNNER` setting to `django.test.simple.DjangoTestSuiteRunner` to fully restore the old test behavior. `DjangoTestSuiteRunner` is deprecated but will not be removed from Django until version 1.8.

### Removal of `django.contrib.gis.tests.GeoDjangoTestSuiteRunner` GeoDjango custom test runner

This is for developers working on the GeoDjango application itself and related to the item above about changes in the test runners:

The `django.contrib.gis.tests.GeoDjangoTestSuiteRunner` test runner has been removed and the standalone GeoDjango tests execution setup it implemented isn't supported anymore. To run the GeoDjango tests simply use the new `DiscoverRunner` and specify the `django.contrib.gis` app.

## Custom user models in tests

The introduction of the new test runner has also slightly changed the way that test models are imported. As a result, any test that overrides `AUTH_USER_MODEL` to test behavior with one of Django's test user models (`django.contrib.auth.tests.custom_user.CustomUser` and `django.contrib.auth.tests.custom_user.ExtensionUser`) must now explicitly import the User model in your test module:

```
from django.contrib.auth.tests.custom_user import CustomUser

@override_settings(AUTH_USER_MODEL='auth.CustomUser')
class CustomUserFeatureTests(TestCase):
    def test_something(self):
        # Test code here ...
```

This import forces the custom user model to be registered. Without this import, the test will be unable to swap in the custom user model, and you will get an error reporting:

```
ImproperlyConfigured: AUTH_USER_MODEL refers to model 'auth.CustomUser' that has not_
↪been installed
```

## Time zone-aware day, month, and week\_day lookups

Django 1.6 introduces time zone support for *day*, *month*, and *week\_day* lookups when `USE_TZ` is `True`. These lookups were previously performed in UTC regardless of the current time zone.

This requires *time zone definitions in the database*. If you're using SQLite, you must install `pytz`. If you're using MySQL, you must install `pytz` and load the time zone tables with `mysql_tzinfo_to_sql`.

### Addition of `QuerySet.dates()`

When the *time zone support* added in Django 1.4 was active, `QuerySet.dates()` lookups returned unexpected results, because the aggregation was performed in UTC. To fix this, Django 1.6 introduces a new API, `QuerySet.dates()`. This requires a few changes in your code.

### `QuerySet.dates()` returns date objects

`QuerySet.dates()` now returns a list of `date`. It used to return a list of `datetime`.

`QuerySet.dates()` returns a list of `datetime`.

### `QuerySet.dates()` no longer usable on `DateTimeField`

`QuerySet.dates()` raises an error if it's used on `DateTimeField` when time zone support is active. Use `QuerySet.dates()` instead.

### `date_hierarchy` requires time zone definitions

The `date_hierarchy` feature of the admin now relies on `QuerySet.dates()` when it's used on a `DateTimeField`.

This requires time zone definitions in the database when `USE_TZ` is `True`. [Learn more](#).

## date\_list in generic views requires time zone definitions

For the same reason, accessing `date_list` in the context of a date-based generic view requires time zone definitions in the database when the view is based on a `DateTimeField` and `USE_TZ` is `True`. [Learn more](#).

## New lookups may clash with model fields

Django 1.6 introduces `hour`, `minute`, and `second` lookups on `DateTimeField`. If you had model fields called `hour`, `minute`, or `second`, the new lookups will clash with your field names. Append an explicit `exact` lookup if this is an issue.

## BooleanField no longer defaults to False

When a `BooleanField` doesn't have an explicit `default`, the implicit default value is `None`. In previous version of Django, it was `False`, but that didn't represent accurately the lack of a value.

Code that relies on the default value being `False` may raise an exception when saving new model instances to the database, because `None` isn't an acceptable value for a `BooleanField`. You should either specify `default=False` in the field definition, or ensure the field is set to `True` or `False` before saving the object.

## Translations and comments in templates

### Extraction of translations after comments

Extraction of translatable literals from templates with the `makemessages` command now correctly detects `i18n` constructs when they are located after a `{# / #}`-type comment on the same line. E.g.:

```
{# A comment #}{% trans "This literal was incorrectly ignored. Not anymore" %}
```

### Location of translator comments

*Comments for translators in templates* specified using `{# / #}` need to be at the end of a line. If they are not, the comments are ignored and `makemessages` will generate a warning. For example:

```
{# Translators: This is ignored #}{% trans "Translate me" %}
{{ title }}{# Translators: Extracted and associated with 'Welcome' below #}
<h1>{% trans "Welcome" %}</h1>
```

### Quoting in reverse()

When reversing URLs, Django didn't apply `urlquote()` to arguments before interpolating them in URL patterns. This bug is fixed in Django 1.6. If you worked around this bug by applying URL quoting before passing arguments to `reverse()`, this may result in double-quoting. If this happens, simply remove the URL quoting from your code. You will also have to replace special characters in URLs used in `assertRedirects()` with their encoded versions.

## Storage of IP addresses in the comments app

The comments app now uses a `GenericIPAddressField` for storing commenters' IP addresses, to support comments submitted from IPv6 addresses. Until now, it stored them in an `IPAddressField`, which is only meant to support IPv4. When saving a comment made from an IPv6 address, the address would be silently truncated on MySQL databases, and raise an exception on Oracle. You will need to change the column type in your database to benefit from this change.

For MySQL, execute this query on your project's database:

```
ALTER TABLE django_comments MODIFY ip_address VARCHAR(39);
```

For Oracle, execute this query:

```
ALTER TABLE DJANGO_COMMENTS MODIFY (ip_address VARCHAR2(39));
```

If you do not apply this change, the behavior is unchanged: on MySQL, IPv6 addresses are silently truncated; on Oracle, an exception is generated. No database change is needed for SQLite or PostgreSQL databases.

## Percent literals in `cursor.execute` queries

When you are running raw SQL queries through the `cursor.execute` method, the rule about doubling percent literals (%) inside the query has been unified. Past behavior depended on the database backend. Now, across all backends, you only need to double literal percent characters if you are also providing replacement parameters. For example:

```
# No parameters, no percent doubling
cursor.execute("SELECT foo FROM bar WHERE baz = '30%'")

# Parameters passed, non-placeholders have to be doubled
cursor.execute("SELECT foo FROM bar WHERE baz = '30%' and id = %s", [self.id])
```

SQLite users need to check and update such queries.

## Help text of model form fields for `ManyToManyField` fields

HTML rendering of model form fields corresponding to `ManyToManyField` model fields used to get the hard-coded sentence:

*Hold down “Control”, or “Command” on a Mac, to select more than one.*

(or its translation to the active locale) imposed as the help legend shown along them if neither `model` nor `form` `help_text` attributes were specified by the user (or this string was appended to any `help_text` that was provided).

Since this happened at the model layer, there was no way to prevent the text from appearing in cases where it wasn't applicable such as form fields that implement user interactions that don't involve a keyboard and/or a mouse.

Starting with Django 1.6, as an ad-hoc temporary backward-compatibility provision, the logic to add the “Hold down...” sentence has been moved to the model form field layer and modified to add the text only when the associated widget is `SelectMultiple` or selected subclasses.

The change can affect you in a backward incompatible way if you employ custom model form fields and/or widgets for `ManyToManyField` model fields whose UIs do rely on the automatic provision of the mentioned hard-coded sentence. These form field implementations need to adapt to the new scenario by providing their own handling of the `help_text` attribute.

Applications that use Django *model form* facilities together with Django built-in form *fields* and *widgets* aren't affected but need to be aware of what's described in *Munging of help text of model form fields for ManyToManyField fields* below.

## QuerySet iteration

The `QuerySet` iteration was changed to immediately convert all fetched rows to `Model` objects. In Django 1.5 and earlier the fetched rows were converted to `Model` objects in chunks of 100.

Existing code will work, but the amount of rows converted to objects might change in certain use cases. Such usages include partially looping over a queryset or any usage which ends up doing `__bool__` or `__contains__`.

Notably most database backends did fetch all the rows in one go already in 1.5.

It is still possible to convert the fetched rows to `Model` objects lazily by using the `iterator()` method.

## BoundField.label\_tag now includes the form's label\_suffix

This is consistent with how methods like `Form.as_p` and `Form.as_ul` render labels.

If you manually render `label_tag` in your templates:

```
{{ form.my_field.label_tag }}: {{ form.my_field }}
```

you'll want to remove the colon (or whatever other separator you may be using) to avoid duplicating it when upgrading to Django 1.6. The following template in Django 1.6 will render identically to the above template in Django 1.5, except that the colon will appear inside the `<label>` element.

```
{{ form.my_field.label_tag }} {{ form.my_field }}
```

will render something like:

```
<label for="id_my_field">My Field:</label> <input id="id_my_field" type="text" name=
↵"my_field" />
```

If you want to keep the current behavior of rendering `label_tag` without the `label_suffix`, instantiate the form `label_suffix=''`. You can also customize the `label_suffix` on a per-field basis using the new `label_suffix` parameter on `label_tag()`.

## Admin views \_changelist\_filters GET parameter

To achieve preserving and restoring list view filters, admin views now pass around the `_changelist_filters` GET parameter. It's important that you account for that change if you have custom admin templates or if your tests rely on the previous URLs. If you want to revert to the original behavior you can set the `preserve_filters` attribute to `False`.

## django.contrib.auth password reset uses base 64 encoding of user PK

Past versions of Django used base 36 encoding of the `User` primary key in the password reset views and URLs (`django.contrib.auth.views.password_reset_confirm()`). Base 36 encoding is sufficient if the user primary key is an integer, however, with the introduction of custom user models in Django 1.5, that assumption may no longer be true.

`django.contrib.auth.views.password_reset_confirm()` has been modified to take a `uidb64` parameter instead of `uidb36`. If you are reversing this view, for example in a custom `password_reset_email.html` template, be sure to update your code.

A temporary shim for `django.contrib.auth.views.password_reset_confirm()` that will allow password reset links generated prior to Django 1.6 to continue to work has been added to provide backwards compatibility; this will be removed in Django 1.7. Thus, as long as your site has been running Django 1.6 for more than `PASSWORD_RESET_TIMEOUT_DAYS`, this change will have no effect. If not (for example, if you upgrade directly from Django 1.5 to Django 1.7), then any password reset links generated before you upgrade to Django 1.7 or later won't work after the upgrade.

In addition, if you have any custom password reset URLs, you will need to update them by replacing `uidb36` with `uidb64` and the dash that follows that pattern with a slash. Also add `_\-` to the list of characters that may match the `uidb64` pattern.

For example:

```
url(r'^reset/(?P<uidb36>[0-9A-Za-z]+)-(P<token>+)/$',
    'django.contrib.auth.views.password_reset_confirm',
    name='password_reset_confirm'),
```

becomes:

```
url(r'^reset/(?P<uidb64>[0-9A-Za-z_\-]+)/(?P<token>+)/$',
    'django.contrib.auth.views.password_reset_confirm',
    name='password_reset_confirm'),
```

You may also want to add the shim to support the old style reset links. Using the example above, you would modify the existing url by replacing `django.contrib.auth.views.password_reset_confirm` with `django.contrib.auth.views.password_reset_confirm_uidb36` and also remove the `name` argument so it doesn't conflict with the new url:

```
url(r'^reset/(?P<uidb36>[0-9A-Za-z]+)-(P<token>+)/$',
    'django.contrib.auth.views.password_reset_confirm_uidb36'),
```

You can remove this URL pattern after your app has been deployed with Django 1.6 for `PASSWORD_RESET_TIMEOUT_DAYS`.

## Default session serialization switched to JSON

Historically, `django.contrib.sessions` used `pickle` to serialize session data before storing it in the backend. If you're using the `signed cookie session backend` and `SECRET_KEY` is known by an attacker (there isn't an inherent vulnerability in Django that would cause it to leak), the attacker could insert a string into his session which, when unpickled, executes arbitrary code on the server. The technique for doing so is simple and easily available on the internet. Although the cookie session storage signs the cookie-stored data to prevent tampering, a `SECRET_KEY` leak immediately escalates to a remote code execution vulnerability.

This attack can be mitigated by serializing session data using JSON rather than `pickle`. To facilitate this, Django 1.5.3 introduced a new setting, `SESSION_SERIALIZER`, to customize the session serialization format. For backwards compatibility, this setting defaulted to using `pickle` in Django 1.5.3, but we've changed the default to JSON in 1.6. If you upgrade and switch from `pickle` to JSON, sessions created before the upgrade will be lost. While JSON serialization does not support all Python objects like `pickle` does, we highly recommend using JSON-serialized sessions. Be aware of the following when checking your code to determine if JSON serialization will work for your application:

- JSON requires string keys, so you will likely run into problems if you are using non-string keys in `request.session`.

- Setting session expiration by passing `datetime` values to `set_expiry()` will not work as `datetime` values are not serializable in JSON. You can use integer values instead.

See the *Session serialization* documentation for more details.

## Object Relational Mapper changes

Django 1.6 contains many changes to the ORM. These changes fall mostly in three categories:

1. Bug fixes (e.g. proper join clauses for generic relations, query combining, join promotion, and join trimming fixes)
2. Preparation for new features. For example the ORM is now internally ready for multicolumn foreign keys.
3. General cleanup.

These changes can result in some compatibility problems. For example, some queries will now generate different table aliases. This can affect `QuerySet.extra()`. In addition some queries will now produce different results. An example is `exclude(condition)` where the condition is a complex one (referencing multijoins inside `Q objects`). In many cases the affected queries didn't produce correct results in Django 1.5 but do now. Unfortunately there are also cases that produce different results, but neither Django 1.5 nor 1.6 produce correct results.

Finally, there have been many changes to the ORM internal APIs.

## Miscellaneous

- The `django.db.models.query.EmptyQuerySet` can't be instantiated any more - it is only usable as a marker class for checking if `none()` has been called: `isinstance(qs.none(), EmptyQuerySet)`
- If your CSS/JavaScript code used to access HTML input widgets by type, you should review it as `type='text'` widgets might be now output as `type='email'`, `type='url'` or `type='number'` depending on their corresponding field type.
- Form field's `error_messages` that contain a placeholder should now always use a named placeholder ("Value '%(value)s' is too big" instead of "Value '%s' is too big"). See the corresponding field documentation for details about the names of the placeholders. The changes in 1.6 particularly affect `DecimalField` and `ModelMultipleChoiceField`.
- Some `error_messages` for `IntegerField`, `EmailField`, `IPAddressField`, `GenericIPAddressField`, and `SlugField` have been suppressed because they duplicated error messages already provided by validators tied to the fields.
- Due to a change in the form validation workflow, `TypedChoiceField.coerce` method should always return a value present in the `choices` field attribute. That limitation should be lifted again in Django 1.7.
- There have been changes in the way timeouts are handled in cache backends. Explicitly passing in `timeout=None` no longer results in using the default timeout. It will now set a non-expiring timeout. Passing 0 into the memcache backend no longer uses the default timeout, and now will set-and-expire-immediately the value.
- The `django.contrib.flatpages` app used to set custom HTTP headers for debugging purposes. This functionality was not documented and made caching ineffective so it has been removed, along with its generic implementation, previously available in `django.core.xheaders`.
- The `XViewMiddleware` has been moved from `django.middleware.doc` to `django.contrib.admindocs.middleware` because it is an implementation detail of `admindocs`, proven not to be reusable in general.

- `GenericIPAddressField` will now only allow blank values if null values are also allowed. Creating a `GenericIPAddressField` where blank is allowed but null is not will trigger a model validation error because blank values are always stored as null. Previously, storing a blank value in a field which did not allow null would cause a database exception at runtime.
- If a `NoReverseMatch` exception is raised from a method when rendering a template, it is not silenced. For example, `{{ obj.view_href }}` will cause template rendering to fail if `view_href()` raises `NoReverseMatch`. There is no change to the `{% url %}` tag, it causes template rendering to fail like always when `NoReverseMatch` is raised.
- `django.test.Client.logout()` now calls `django.contrib.auth.logout()` which will send the `user_logged_out()` signal.
- `Authentication views` are now reversed by name, not their locations in `django.contrib.auth.views`. If you are using the views without a name, you should update your `urlpatterns` to use `url()` with the name parameter. For example:

```
(r'^reset/done/$', 'django.contrib.auth.views.password_reset_complete')
```

becomes:

```
url(r'^reset/done/$', 'django.contrib.auth.views.password_reset_complete', name=  
→'password_reset_complete')
```

- `RedirectView` now has a `pattern_name` attribute which allows it to choose the target by reversing the URL.
- In Django 1.4 and 1.5, a blank string was unintentionally not considered to be a valid password. This meant `set_password()` would save a blank password as an unusable password like `set_unusable_password()` does, and thus `check_password()` always returned `False` for blank passwords. This has been corrected in this release: blank passwords are now valid.
- The admin `changelist_view` previously accepted a `pop` GET parameter to signify it was to be displayed in a popup. This parameter has been renamed to `_popup` to be consistent with the rest of the admin views. You should update your custom templates if they use the previous parameter name.
- `validate_email()` now accepts email addresses with `localhost` as the domain.
- The new `makemessages --keep-pot` option prevents deleting the temporary `.pot` file generated before creating the `.po` file.
- The undocumented `django.core.servers.basehttp.WSGIServerException` has been removed. Use `socket.error` provided by the standard library instead. This change was also released in Django 1.5.5.
- The signature of `django.views.generic.base.RedirectView.get_redirect_url()` has changed and now accepts positional arguments as well (`*args, **kwargs`). Any unnamed captured group will now be passed to `get_redirect_url()` which may result in a `TypeError` if you don't update the signature of your custom method.

## Features deprecated in 1.6

### Transaction management APIs

Transaction management was completely overhauled in Django 1.6, and the current APIs are deprecated:

- `django.middleware.transaction.TransactionMiddleware`
- `django.db.transaction.autocommit`
- `django.db.transaction.commit_on_success`

- `django.db.transaction.commit_manually`
- the `TRANSACTIONS_MANAGED` setting

### `django.contrib.comments`

Django's comment framework has been deprecated and is no longer supported. It will be available in Django 1.6 and 1.7, and removed in Django 1.8. Most users will be better served with a custom solution, or a hosted product like [Disqus](#).

The code formerly known as `django.contrib.comments` is [still available in an external repository](#).

### Support for PostgreSQL versions older than 8.4

The end of upstream support periods was reached in December 2011 for PostgreSQL 8.2 and in February 2013 for 8.3. As a consequence, Django 1.6 sets 8.4 as the minimum PostgreSQL version it officially supports.

You're strongly encouraged to use the most recent version of PostgreSQL available, because of performance improvements and to take advantage of the native streaming replication available in PostgreSQL 9.x.

### Changes to `cycle` and `firstof`

The template system generally escapes all variables to avoid XSS attacks. However, due to an accident of history, the `cycle` and `firstof` tags render their arguments as-is.

Django 1.6 starts a process to correct this inconsistency. The `future` template library provides alternate implementations of `cycle` and `firstof` that autoescape their inputs. If you're using these tags, you're encouraged to include the following line at the top of your templates to enable the new behavior:

```
{% load cycle from future %}
```

or:

```
{% load firstof from future %}
```

The tags implementing the old behavior have been deprecated, and in Django 1.8, the old behavior will be replaced with the new behavior. To ensure compatibility with future versions of Django, existing templates should be modified to use the `future` versions.

If necessary, you can temporarily disable auto-escaping with `mark_safe()` or `{% autoescape off %}`.

### `CACHE_MIDDLEWARE_ANONYMOUS_ONLY` setting

`CacheMiddleware` and `UpdateCacheMiddleware` used to provide a way to cache requests only if they weren't made by a logged-in user. This mechanism was largely ineffective because the middleware correctly takes into account the `Vary: Cookie` HTTP header, and this header is being set on a variety of occasions, such as:

- accessing the session, or
- using CSRF protection, which is turned on by default, or
- using a client-side library which sets cookies, like [Google Analytics](#).

This makes the cache effectively work on a per-session basis regardless of the `CACHE_MIDDLEWARE_ANONYMOUS_ONLY` setting.

### **SEND\_BROKEN\_LINK\_EMAILS setting**

`CommonMiddleware` used to provide basic reporting of broken links by email when `SEND_BROKEN_LINK_EMAILS` is set to `True`.

Because of intractable ordering problems between `CommonMiddleware` and `LocaleMiddleware`, this feature was split out into a new middleware: `BrokenLinkEmailsMiddleware`.

If you're relying on this feature, you should add `'django.middleware.common.BrokenLinkEmailsMiddleware'` to your `MIDDLEWARE_CLASSES` setting and remove `SEND_BROKEN_LINK_EMAILS` from your settings.

### **`_has_changed` method on widgets**

If you defined your own form widgets and defined the `_has_changed` method on a widget, you should now define this method on the form field itself.

### **`module_name` model `_meta` attribute**

`Model._meta.module_name` was renamed to `model_name`. Despite being a private API, it will go through a regular deprecation path.

### **`get_(add|change|delete)_permission` model `_meta` methods**

`Model._meta.get_(add|change|delete)_permission` methods were deprecated. Even if they were not part of the public API they'll also go through a regular deprecation path. You can replace them with `django.contrib.auth.get_permission_codename('action', Model._meta)` where `'action'` is `'add'`, `'change'`, or `'delete'`.

### **`get_query_set` and similar methods renamed to `get_queryset`**

Methods that return a `QuerySet` such as `Manager.get_query_set` or `ModelAdmin.queryset` have been renamed to `get_queryset`.

If you are writing a library that implements, for example, a `Manager.get_query_set` method, and you need to support old Django versions, you should rename the method and conditionally add an alias with the old name:

```
class CustomManager(models.Manager):
    def get_queryset(self):
        pass # ...

    if django.VERSION < (1, 6):
        get_query_set = get_queryset

    # For Django >= 1.6, models.Manager provides a get_query_set fallback
    # that emits a warning when used.
```

If you are writing a library that needs to call the `get_queryset` method and must support old Django versions, you should write:

```

get_queryset = (some_manager.get_query_set
                if hasattr(some_manager, 'get_query_set')
                else some_manager.get_queryset)
return get_queryset() # etc

```

In the general case of a custom manager that both implements its own `get_queryset` method and calls that method, and needs to work with older Django versions, and libraries that have not been updated yet, it is useful to define a `get_queryset_compat` method as below and use it internally to your manager:

```

class YourCustomManager(models.Manager):
    def get_queryset(self):
        return YourCustomQuerySet() # for example

    if django.VERSION < (1, 6):
        get_query_set = get_queryset

    def active(self): # for example
        return self.get_queryset_compat().filter(active=True)

    def get_queryset_compat(self):
        get_queryset = (self.get_query_set
                        if hasattr(self, 'get_query_set')
                        else self.get_queryset)
        return get_queryset()

```

This helps to minimize the changes that are needed, but also works correctly in the case of subclasses (such as `RelatedManagers` from Django 1.5) which might override either `get_query_set` or `get_queryset`.

### shortcut view and URLconf

The shortcut view was moved from `django.views.defaults` to `django.contrib.contenttypes.views` shortly after the 1.0 release, but the old location was never deprecated. This oversight was corrected in Django 1.6 and you should now use the new location.

The URLconf `django.conf.urls.shortcut` was also deprecated. If you're including it in an URLconf, simply replace:

```
(r'^prefix/', include('django.conf.urls.shortcut')),
```

with:

```
(r'^prefix/(?P<content_type_id>\d+)/(?P<object_id>.*)/$', 'django.contrib.
↳contenttypes.views.shortcut'),
```

### ModelForm without fields or exclude

Previously, if you wanted a `ModelForm` to use all fields on the model, you could simply omit the `Meta.fields` attribute, and all fields would be used.

This can lead to security problems where fields are added to the model and, unintentionally, automatically become editable by end users. In some cases, particular with boolean fields, it is possible for this problem to be completely invisible. This is a form of [Mass assignment vulnerability](#).

For this reason, this behavior is deprecated, and using the `Meta.exclude` option is strongly discouraged. Instead, all fields that are intended for inclusion in the form should be listed explicitly in the `fields` attribute.

If this security concern really does not apply in your case, there is a shortcut to explicitly indicate that all fields should be used - use the special value `"__all__"` for the `fields` attribute:

```
class MyModelForm(ModelForm):
    class Meta:
        fields = "__all__"
        model = MyModel
```

If you have custom `ModelForms` that only need to be used in the admin, there is another option. The admin has its own methods for defining fields (`fieldset`s etc.), and so adding a list of fields to the `ModelForm` is redundant. Instead, simply omit the `Meta` inner class of the `ModelForm`, or omit the `Meta.model` attribute. Since the `ModelAdmin` subclass knows which model it is for, it can add the necessary attributes to derive a functioning `ModelForm`. This behavior also works for earlier Django versions.

### UpdateView and CreateView without explicit fields

The generic views `CreateView` and `UpdateView`, and anything else derived from `ModelFormMixin`, are vulnerable to the security problem described in the section above, because they can automatically create a `ModelForm` that uses all fields for a model.

For this reason, if you use these views for editing models, you must also supply the `fields` attribute (new in Django 1.6), which is a list of model fields and works in the same way as the `ModelForm.Meta.fields` attribute. Alternatively, you can set the `form_class` attribute to a `ModelForm` that explicitly defines the fields to be used. Defining an `UpdateView` or `CreateView` subclass to be used with a model but without an explicit list of fields is deprecated.

### Munging of help text of model form fields for `ManyToManyField` fields

All special handling of the `help_text` attribute of `ManyToManyField` model fields performed by standard model or model form fields as described in *Help text of model form fields for `ManyToManyField` fields* above is deprecated and will be removed in Django 1.8.

Help text of these fields will need to be handled either by applications, custom form fields or widgets, just like happens with the rest of the model field types.

## 9.1.6 1.5 release

### Django 1.5.12 release notes

January 2, 2015

Django 1.5.12 fixes a regression in the 1.5.9 security release.

#### Bugfixes

- Fixed a regression with dynamically generated inlines and allowed field references in the admin (#23754).

### Django 1.5.11 release notes

October 22, 2014

Django 1.5.11 fixes a couple regressions in the 1.5.9 security release.

## Bugfixes

- Allowed related many-to-many fields to be referenced in the admin (#23604).
- Allowed inline and hidden references to admin fields (#23431).

## Django 1.5.10 release notes

*September 2, 2014*

Django 1.5.10 fixes a regression in the 1.5.9 security release.

## Bugfixes

- Allowed inherited and m2m fields to be referenced in the admin (#22486)

## Django 1.5.9 release notes

*August 20, 2014*

Django 1.5.9 fixes several security issues in 1.5.8.

### **`reverse()` could generate URLs pointing to other hosts**

In certain situations, URL reversing could generate scheme-relative URLs (URLs starting with two slashes), which could unexpectedly redirect a user to a different host. An attacker could exploit this, for example, by redirecting users to a phishing site designed to ask for user's passwords.

To remedy this, URL reversing now ensures that no URL starts with two slashes (`//`), replacing the second slash with its URL encoded counterpart (`%2F`). This approach ensures that semantics stay the same, while making the URL relative to the domain and not to the scheme.

### **File upload denial-of-service**

Before this release, Django's file upload handling in its default configuration may degrade to producing a huge number of `os.stat()` system calls when a duplicate filename is uploaded. Since `stat()` may invoke IO, this may produce a huge data-dependent slowdown that slowly worsens over time. The net result is that given enough time, a user with the ability to upload files can cause poor performance in the upload handler, eventually causing it to become very slow simply by uploading 0-byte files. At this point, even a slow network connection and few HTTP requests would be all that is necessary to make a site unavailable.

We've remedied the issue by changing the algorithm for generating file names if a file with the uploaded name already exists. `Storage.get_available_name()` now appends an underscore plus a random 7 character alphanumeric string (e.g. `"_x3a1gho"`), rather than iterating through an underscore followed by a number (e.g. `"_1"`, `"_2"`, etc.).

### **RemoteUserMiddleware session hijacking**

When using the `RemoteUserMiddleware` and the `RemoteUserBackend`, a change to the `REMOTE_USER` header between requests without an intervening logout could result in the prior user's session being co-opted by the subsequent user. The middleware now logs the user out on a failed login attempt.

## Data leakage via query string manipulation in `contrib.admin`

In older versions of Django it was possible to reveal any field’s data by modifying the “popup” and “to\_field” parameters of the query string on an admin change form page. For example, requesting a URL like `/admin/auth/user/?pop=1&t=password` and viewing the page’s HTML allowed viewing the password hash of each user. While the admin requires users to have permissions to view the change form pages in the first place, this could leak data if you rely on users having access to view only certain fields on a model.

To address the issue, an exception will now be raised if a `to_field` value that isn’t a related field to a model that has been registered with the admin is specified.

## Django 1.5.8 release notes

*May 14, 2014*

Django 1.5.8 fixes two security issues in 1.5.8.

### Caches may incorrectly be allowed to store and serve private data

In certain situations, Django may allow caches to store private data related to a particular session and then serve that data to requests with a different session, or no session at all. This can lead to information disclosure and can be a vector for cache poisoning.

When using Django sessions, Django will set a `Vary: Cookie` header to ensure caches do not serve cached data to requests from other sessions. However, older versions of Internet Explorer (most likely only Internet Explorer 6, and Internet Explorer 7 if run on Windows XP or Windows Server 2003) are unable to handle the `Vary` header in combination with many content types. Therefore, Django would remove the header if the request was made by Internet Explorer.

To remedy this, the special behavior for these older Internet Explorer versions has been removed, and the `Vary` header is no longer stripped from the response. In addition, modifications to the `Cache-Control` header for all Internet Explorer requests with a `Content-Disposition` header have also been removed as they were found to have similar issues.

### Malformed redirect URLs from user input not correctly validated

The validation for redirects did not correctly validate some malformed URLs, which are accepted by some browsers. This allows a user to be redirected to an unsafe URL unexpectedly.

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()`, `django.contrib.comments`, and *il8n*) to redirect the user to an “on success” URL. The security checks for these redirects (namely `django.utils.http.is_safe_url()`) did not correctly validate some malformed URLs, such as `http:\\djangoproject.com`, which are accepted by some browsers with more liberal URL parsing.

To remedy this, the validation in `is_safe_url()` has been tightened to be able to handle and correctly validate these malformed URLs.

## Django 1.5.7 release notes

*April 28, 2014*

Django 1.5.7 fixes a regression in the 1.5.6 security release.

## Bugfixes

- Restored the ability to `reverse()` views created using `functools.partial()` (#22486).

## Django 1.5.6 release notes

April 21, 2014

Django 1.5.6 fixes several bugs in 1.5.5, including three security issues.

### Unexpected code execution using `reverse()`

Django’s URL handling is based on a mapping of regex patterns (representing the URLs) to callable views, and Django’s own processing consists of matching a requested URL against those patterns to determine the appropriate view to invoke.

Django also provides a convenience function – `reverse()` – which performs this process in the opposite direction. The `reverse()` function takes information about a view and returns a URL which would invoke that view. Use of `reverse()` is encouraged for application developers, as the output of `reverse()` is always based on the current URL patterns, meaning developers do not need to change other code when making changes to URLs.

One argument signature for `reverse()` is to pass a dotted Python path to the desired view. In this situation, Django will import the module indicated by that dotted path as part of generating the resulting URL. If such a module has import-time side effects, those side effects will occur.

Thus it is possible for an attacker to cause unexpected code execution, given the following conditions:

1. One or more views are present which construct a URL based on user input (commonly, a “next” parameter in a querystring indicating where to redirect upon successful completion of an action).
2. One or more modules are known to an attacker to exist on the server’s Python import path, which perform code execution with side effects on importing.

To remedy this, `reverse()` will now only accept and import dotted paths based on the view-containing modules listed in the project’s *URL pattern configuration*, so as to ensure that only modules the developer intended to be imported in this fashion can or will be imported.

### Caching of anonymous pages could reveal CSRF token

Django includes both a *caching framework* and a system for *preventing cross-site request forgery (CSRF) attacks*. The CSRF-protection system is based on a random nonce sent to the client in a cookie which must be sent by the client on future requests and, in forms, a hidden value which must be submitted back with the form.

The caching framework includes an option to cache responses to anonymous (i.e., unauthenticated) clients.

When the first anonymous request to a given page is by a client which did not have a CSRF cookie, the cache framework will also cache the CSRF cookie and serve the same nonce to other anonymous clients who do not have a CSRF cookie. This can allow an attacker to obtain a valid CSRF cookie value and perform attacks which bypass the check for the cookie.

To remedy this, the caching framework will no longer cache such responses. The heuristic for this will be:

1. If the incoming request did not submit any cookies, and
2. If the response did send one or more cookies, and
3. If the `Vary: Cookie` header is set on the response, then the response will not be cached.

## MySQL typecasting

The MySQL database is known to “typecast” on certain queries; for example, when querying a table which contains string values, but using a query which filters based on an integer value, MySQL will first silently coerce the strings to integers and return a result based on that.

If a query is performed without first converting values to the appropriate type, this can produce unexpected results, similar to what would occur if the query itself had been manipulated.

Django’s model field classes are aware of their own types and most such classes perform explicit conversion of query arguments to the correct database-level type before querying. However, three model field classes did not correctly convert their arguments:

- `FilePathField`
- `GenericIPAddressField`
- `IPAddressField`

These three fields have been updated to convert their arguments to the correct types before querying.

Additionally, developers of custom model fields are now warned via documentation to ensure their custom field classes will perform appropriate type conversions, and users of the `raw()` and `extra()` query methods – which allow the developer to supply raw SQL or SQL fragments – will be advised to ensure they perform appropriate manual type conversions prior to executing queries.

## Bugfixes

- Fixed `ModelBackend` raising `UnboundLocalError` if `get_user_model()` raised an error (#21439).

Additionally, Django’s vendored version of six, `django.utils.six`, has been upgraded to the latest release (1.6.1).

## Django 1.5.5 release notes

October 23, 2013

Django 1.5.5 fixes a couple security-related bugs and several other bugs in the 1.5 series.

### Readdressed denial-of-service via password hashers

Django 1.5.4 imposes a 4096-byte limit on passwords in order to mitigate a denial-of-service attack through submission of bogus but extremely large passwords. In Django 1.5.5, we’ve reverted this change and instead improved the speed of our PBKDF2 algorithm by not rehashing the key on every iteration.

### Properly rotate CSRF token on login

This behavior introduced as a security hardening measure in Django 1.5.2 did not work properly and is now fixed.

## Bugfixes

- Fixed a data corruption bug with `datetime_safe.datetime.combine` (#21256).
- Fixed a Python 3 incompatibility in `django.utils.text.unescape_entities()` (#21185).

- Fixed a couple data corruption issues with `QuerySet` edge cases under Oracle and MySQL (#21203, #21126).
- Fixed crashes when using combinations of `annotate()`, `select_related()`, and `only()` (#16436).

### Backwards incompatible changes

- The undocumented `django.core.servers.basehttp.WSGIServerException` has been removed. Use `socket.error` provided by the standard library instead.

### Django 1.5.4 release notes

September 14, 2013

This is Django 1.5.4, the fourth release in the Django 1.5 series. It addresses two security issues and one bug.

#### Denial-of-service via password hashers

In previous versions of Django, no limit was imposed on the plaintext length of a password. This allowed a denial-of-service attack through submission of bogus but extremely large passwords, tying up server resources performing the (expensive, and increasingly expensive with the length of the password) calculation of the corresponding hash.

As of 1.5.4, Django's authentication framework imposes a 4096-byte limit on passwords, and will fail authentication with any submitted password of greater length.

#### Corrected usage of `sensitive_post_parameters()` in `django.contrib.auth's admin`

The decoration of the `add_view` and `user_change_password` user admin views with `sensitive_post_parameters()` did not include `method_decorator()` (required since the views are methods) resulting in the decorator not being properly applied. This usage has been fixed and `sensitive_post_parameters()` will now throw an exception if it's improperly used.

### Bugfixes

- Fixed a bug that prevented a `QuerySet` that uses `prefetch_related()` from being pickled and unpickled more than once (the second pickling attempt raised an exception) (#21102).

### Django 1.5.3 release notes

September 10, 2013

This is Django 1.5.3, the third release in the Django 1.5 series. It addresses one security issue and also contains an opt-in feature to enhance the security of `django.contrib.sessions`.

#### Directory traversal vulnerability in `ssi` template tag

In previous versions of Django it was possible to bypass the `ALLOWED_INCLUDE_ROOTS` setting used for security with the `ssi` template tag by specifying a relative path that starts with one of the allowed roots. For example, if `ALLOWED_INCLUDE_ROOTS = ("/var/www",)` the following would be possible:

```
{% ssi "/var/www/../../etc/passwd" %}
```

In practice this is not a very common problem, as it would require the template author to put the `ssi` file in a user-controlled variable, but it's possible in principle.

### Mitigating a remote-code execution vulnerability in `django.contrib.sessions`

`django.contrib.sessions` currently uses `pickle` to serialize session data before storing it in the backend. If you're using the *signed cookie session backend* and `SECRET_KEY` is known by an attacker (there isn't an inherent vulnerability in Django that would cause it to leak), the attacker could insert a string into his session which, when unpickled, executes arbitrary code on the server. The technique for doing so is simple and easily available on the internet. Although the cookie session storage signs the cookie-stored data to prevent tampering, a `SECRET_KEY` leak immediately escalates to a remote code execution vulnerability.

This attack can be mitigated by serializing session data using JSON rather than `pickle`. To facilitate this, Django 1.5.3 introduces a new setting, `SESSION_SERIALIZER`, to customize the session serialization format. For backwards compatibility, this setting defaults to using `pickle`. While JSON serialization does not support all Python objects like `pickle` does, we highly recommend switching to JSON-serialized values. Also, as JSON requires string keys, you will likely run into problems if you are using non-string keys in `request.session`. See the *Session serialization* documentation for more details.

### Django 1.5.2 release notes

August 13, 2013

This is Django 1.5.2, a bugfix and security release for Django 1.5.

### Mitigated possible XSS attack via user-supplied redirect URLs

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()`, `django.contrib.comments`, and *i18n*) to redirect the user to an "on success" URL. The security checks for these redirects (namely `django.utils.http.is_safe_url()`) didn't check if the scheme is `http(s)` and as such allowed `javascript:...` URLs to be entered. If a developer relied on `is_safe_url()` to provide safe redirect targets and put such a URL into a link, they could suffer from a XSS attack. This bug doesn't affect Django currently, since we only put this URL into the `Location` response header and browsers seem to ignore JavaScript there.

### XSS vulnerability in `django.contrib.admin`

If a `URLField` is used in Django 1.5, it displays the current value of the field and a link to the target on the admin change page. The display routine of this widget was flawed and allowed for XSS.

### Bugfixes

- Fixed a crash with `prefetch_related()` (#19607) as well as some `pickle` regressions with `prefetch_related` (#20157 and #20257).
- Fixed a regression in `django.contrib.gis` in the Google Map output on Python 3 (#20773).
- Made `DjangoTestSuiteRunner.setup_databases` properly handle aliases for the default database (#19940) and prevented `teardown_databases` from attempting to tear down aliases (#20681).

- Fixed the `django.core.cache.backends.memcached.MemcachedCache` backend's `get_many()` method on Python 3 (#20722).
- Fixed `django.contrib.humanize` translation syntax errors. Affected languages: Mexican Spanish, Mongolian, Romanian, Turkish (#20695).
- Added support for wheel packages (#19252).
- The CSRF token now rotates when a user logs in.
- Some Python 3 compatibility fixes including #20212 and #20025.
- Fixed some rare cases where `get()` exceptions recursed infinitely (#20278).
- `makemessages` no longer crashes with `UnicodeDecodeError` (#20354).
- Fixed `geojson` detection with `Spatialite`.
- `assertContains()` once again works with binary content (#20237).
- Fixed `ManyToManyField` if it has a unicode name parameter (#20207).
- Ensured that the WSGI request's path is correctly based on the `SCRIPT_NAME` environment variable or the `FORCE_SCRIPT_NAME` setting, regardless of whether or not either has a trailing slash (#20169).
- Fixed an obscure bug with the `override_settings()` decorator. If you hit an `AttributeError: 'Settings' object has no attribute '_original_allowed_hosts'` exception, it's probably fixed (#20636).

## Django 1.5.1 release notes

March 28, 2013

This is Django 1.5.1, a bugfix release for Django 1.5. It's completely backwards compatible with Django 1.5, but includes a handful of fixes.

The biggest fix is for a memory leak introduced in Django 1.5. Under certain circumstances, repeated iteration over querysets could leak memory - sometimes quite a bit of it. If you'd like more information, the details are in [our ticket tracker](#) (and in [a related issue](#) in Python itself).

If you've noticed memory problems under Django 1.5, upgrading to 1.5.1 should fix those issues.

Django 1.5.1 also includes a couple smaller fixes:

- Module-level warnings emitted during tests are no longer silently hidden (#18985).
- Prevented filtering on password hashes in the user admin (#20078).

## Django 1.5 release notes

February 26, 2013

Welcome to Django 1.5!

These release notes cover the *new features*, as well as some *backwards incompatible changes* you'll want to be aware of when upgrading from Django 1.4 or older versions. We've also dropped some features, which are detailed in *our deprecation plan*, and we've *begun the deprecation process for some features*.

## Overview

The biggest new feature in Django 1.5 is the *configurable User model*. Before Django 1.5, applications that wanted to use Django’s auth framework (*django.contrib.auth*) were forced to use Django’s definition of a “user”. In Django 1.5, you can now swap out the `User` model for one that you write yourself. This could be a simple extension to the existing `User` model – for example, you could add a Twitter or Facebook ID field – or you could completely replace the `User` with one totally customized for your site.

Django 1.5 is also the first release with *Python 3 support*! We’re labeling this support “experimental” because we don’t yet consider it production-ready, but everything’s in place for you to start porting your apps to Python 3. Our next release, Django 1.6, will support Python 3 without reservations.

Other notable new features in Django 1.5 include:

- *Support for saving a subset of model’s fields* - `Model.save()` now accepts an `update_fields` argument, letting you specify which fields are written back to the database when you call `save()`. This can help in high-concurrency operations, and can improve performance.
- Better *support for streaming responses* via the new `StreamingHttpResponse` response class.
- *GeoDjango* now supports PostGIS 2.0.
- ... and more; *see below*.

Wherever possible we try to introduce new features in a backwards-compatible manner per *our API stability policy*. However, as with previous releases, Django 1.5 ships with some minor *backwards incompatible changes*; people upgrading from previous versions of Django should read that list carefully.

One deprecated feature worth noting is the shift to “new-style” `url` tag. Prior to Django 1.3, syntax like `{% url myview %}` was interpreted incorrectly (Django considered “myview” to be a literal name of a view, not a template variable named `myview`). Django 1.3 and above introduced the `{% load url from future %}` syntax to bring in the corrected behavior where `myview` was seen as a variable.

The upshot of this is that if you are not using `{% load url from future %}` in your templates, you’ll need to change tags like `{% url myview %}` to `{% url "myview" %}`. If you *were* using `{% load url from future %}` you can simply remove that line under Django 1.5

## Python compatibility

Django 1.5 requires Python 2.6.5 or above, though we **highly recommend** Python 2.7.3 or above. Support for Python 2.5 and below has been dropped.

This change should affect only a small number of Django users, as most operating-system vendors today are shipping Python 2.6 or newer as their default version. If you’re still using Python 2.5, however, you’ll need to stick to Django 1.4 until you can upgrade your Python version. Per *our support policy*, Django 1.4 will continue to receive security support until the release of Django 1.6.

Django 1.5 does not run on a Jython final release, because Jython’s latest release doesn’t currently support Python 2.6. However, Jython currently does offer an alpha release featuring 2.7 support, and Django 1.5 supports that alpha release.

## Python 3 support

Django 1.5 introduces support for Python 3 - specifically, Python 3.2 and above. This comes in the form of a **single** codebase; you don’t need to install a different version of Django on Python 3. This means that you can write applications targeted for just Python 2, just Python 3, or single applications that support both platforms.

However, we’re labeling this support “experimental” for now: although it’s received extensive testing via our automated test suite, it’s received very little real-world testing. We’ve done our best to eliminate bugs, but we can’t be sure we covered all possible uses of Django.

Some features of Django aren’t available because they depend on third-party software that hasn’t been ported to Python 3 yet, including:

- the MySQL database backend (depends on MySQLdb)
- `ImageField` (depends on PIL)
- `LiveServerTestCase` (depends on Selenium WebDriver)

Further, Django’s more than a web framework; it’s an ecosystem of pluggable components. At this point, very few third-party applications have been ported to Python 3, so it’s unlikely that a real-world application will have all its dependencies satisfied under Python 3.

Thus, we’re recommending that Django 1.5 not be used in production under Python 3. Instead, use this opportunity to begin *porting applications to Python 3*. If you’re an author of a pluggable component, we encourage you to start porting now.

We plan to offer first-class, production-ready support for Python 3 in our next release, Django 1.6.

## What’s new in Django 1.5

### Configurable User model

In Django 1.5, you can now use your own model as the store for user-related data. If your project needs a username with more than 30 characters, or if you want to store user’s names in a format other than first name/last name, or you want to put custom profile information onto your User object, you can now do so.

If you have a third-party reusable application that references the User model, you may need to make some changes to the way you reference User instances. You should also document any specific features of the User model that your application relies upon.

See the *documentation on custom user models* for more details.

### Support for saving a subset of model’s fields

The method `Model.save()` has a new keyword argument `update_fields`. By using this argument it is possible to save only a select list of model’s fields. This can be useful for performance reasons or when trying to avoid overwriting concurrent changes.

Deferred instances (those loaded by `.only()` or `.defer()`) will automatically save just the loaded fields. If any field is set manually after load, that field will also get updated on save.

See the `Model.save()` documentation for more details.

### Caching of related model instances

When traversing relations, the ORM will avoid re-fetching objects that were previously loaded. For example, with the tutorial’s models:

```
>>> first_poll = Poll.objects.all()[0]
>>> first_choice = first_poll.choice_set.all()[0]
>>> first_choice.poll is first_poll
True
```

In Django 1.5, the third line no longer triggers a new SQL query to fetch `first_choice.poll`; it was set by the second line.

For one-to-one relationships, both sides can be cached. For many-to-one relationships, only the single side of the relationship can be cached. This is particularly helpful in combination with `prefetch_related`.

### Explicit support for streaming responses

Before Django 1.5, it was possible to create a streaming response by passing an iterator to `HttpResponse`. But this was unreliable: any middleware that accessed the `content` attribute would consume the iterator prematurely.

You can now explicitly generate a streaming response with the new `StreamingHttpResponse` class. This class exposes a `streaming_content` attribute which is an iterator.

Since `StreamingHttpResponse` does not have a `content` attribute, middleware that needs access to the response content must test for streaming responses and behave accordingly.

### `{% verbatim %}` template tag

To make it easier to deal with JavaScript templates which collide with Django’s syntax, you can now use the `verbatim` block tag to avoid parsing the tag’s content.

### Retrieval of `ContentType` instances associated with proxy models

The methods `ContentTypeManager.get_for_model()` and `ContentTypeManager.get_for_models()` have a new keyword argument – respectively `for_concrete_model` and `for_concrete_models`. By passing `False` using this argument it is now possible to retrieve the `ContentType` associated with proxy models.

### New `view` variable in class-based views context

In all *generic class-based views* (or any class-based view inheriting from `ContextMixin`), the context dictionary contains a `view` variable that points to the `View` instance.

### GeoDjango

- `LineString` and `MultiLineString` GEOS objects now support the `interpolate()` and `project()` methods (so-called linear referencing).
- The `wkb` and `hex` properties of `GEOSGeometry` objects preserve the Z dimension.
- Support for PostGIS 2.0 has been added and support for GDAL < 1.5 has been dropped.

### New tutorials

Additions to the docs include a revamped *Tutorial 3* and a new *tutorial on testing*. A new section, “Advanced Tutorials”, offers *How to write reusable apps* as well as a step-by-step guide for new contributors in *Writing your first patch for Django*.

## Minor features

Django 1.5 also includes several smaller improvements worth noting:

- The template engine now interprets `True`, `False` and `None` as the corresponding Python objects.
- `django.utils.timezone` provides a helper for converting aware datetimes between time zones. See `localtime()`.
- The generic views support `OPTIONS` requests.
- Management commands do not raise `SystemExit` any more when called by code from `call_command()`. Any exception raised by the command (mostly `CommandError`) is propagated.  
Moreover, when you output errors or messages in your custom commands, you should now use `self.stdout.write('message')` and `self.stderr.write('error')` (see the note on *management commands output*).
- The `dumpdata` management command outputs one row at a time, preventing out-of-memory errors when dumping large datasets.
- In the `localflavor` for Canada, “pq” was added to the acceptable codes for Quebec. It’s an old abbreviation.
- The `receiver` decorator is now able to connect to more than one signal by supplying a list of signals.
- In the admin, you can now filter users by groups which they are members of.
- `QuerySet.bulk_create()` now has a `batch_size` argument. By default the `batch_size` is unlimited except for SQLite where single batch is limited so that 999 parameters per query isn’t exceeded.
- The `LOGIN_URL` and `LOGIN_REDIRECT_URL` settings now also accept view function names and *named URL patterns*. This allows you to reduce configuration duplication. More information can be found in the `login_required()` documentation.
- Django now provides a `mod_wsgi` *auth handler*.
- The `QuerySet.delete()` and `Model.delete()` can now take fast-path in some cases. The fast-path allows for less queries and less objects fetched into memory. See `QuerySet.delete()` for details.
- An instance of `ResolverMatch` is stored on the request as `resolver_match`.
- By default, all logging messages reaching the `django` logger when `DEBUG` is `True` are sent to the console (unless you redefine the logger in your `LOGGING` setting).
- When using `RequestContext`, it is now possible to look up permissions by using `{% if 'someapp.someperm' in perms %}` in templates.
- It’s not required any more to have `404.html` and `500.html` templates in the root templates directory. Django will output some basic error messages for both situations when those templates are not found. Of course, it’s still recommended as good practice to provide those templates in order to present pretty error pages to the user.
- `django.contrib.auth` provides a new signal that is emitted whenever a user fails to login successfully. See `user_login_failed`
- The new `loaddata --ignorenonexistent` option ignore data for fields that no longer exist.
- `assertXMLEqual()` and `assertXMLNotEqual()` new assertions allow you to test equality for XML content at a semantic level, without caring for syntax differences (spaces, attribute order, etc.).
- `RemoteUserMiddleware` now forces logout when the `REMOTE_USER` header disappears during the same browser session.
- The *cache-based session backend* can store session data in a non-default cache.

- Multi-column indexes can now be created on models. Read the *index\_together* documentation for more information.
- During Django’s logging configuration verbose Deprecation warnings are enabled and warnings are captured into the logging system. Logged warnings are routed through the `console` logging handler, which by default requires `DEBUG` to be True for output to be generated. The result is that DeprecationWarnings should be printed to the console in development environments the way they have been in Python versions < 2.7.
- The API for `django.contrib.admin.ModelAdmin.message_user()` method has been modified to accept additional arguments adding capabilities similar to `django.contrib.messages.add_message()`. This is useful for generating error messages from admin actions.
- The admin’s list filters can now be customized per-request thanks to the new `django.contrib.admin.ModelAdmin.get_list_filter()` method.

## Backwards incompatible changes in 1.5

**Warning:** In addition to the changes outlined in this section, be sure to review the *deprecation plan* for any features that have been removed. If you haven’t updated your code within the deprecation timeline for a given feature, its removal may appear as a backwards incompatible change.

### ALLOWED\_HOSTS required in production

The new `ALLOWED_HOSTS` setting validates the request’s `Host` header and protects against host-poisoning attacks. This setting is now required whenever `DEBUG` is `False`, or else `django.http.HttpRequest.get_host()` will raise `SuspiciousOperation`. For more details see the *full documentation* for the new setting.

### Managers on abstract models

Abstract models are able to define a custom manager, and that manager *will be inherited by any concrete models extending the abstract model*. However, if you try to use the abstract model to call a method on the manager, an exception will now be raised. Previously, the call would have been permitted, but would have failed as soon as any database operation was attempted (usually with a “table does not exist” error from the database).

If you have functionality on a manager that you have been invoking using the abstract class, you should migrate that logic to a Python `staticmethod` or `classmethod` on the abstract class.

### Context in year archive class-based views

For consistency with the other date-based generic views, `YearArchiveView` now passes `year` in the context as a `datetime.date` rather than a string. If you are using `{{ year }}` in your templates, you must replace it with `{{ year|date:"Y" }}`.

`next_year` and `previous_year` were also added in the context. They are calculated according to `allow_empty` and `allow_future`.

### Context in year and month archive class-based views

`YearArchiveView` and `MonthArchiveView` were documented to provide a `date_list` sorted in ascending order in the context, like their function-based predecessors, but it actually was in descending order. In 1.5, the doc-

umented order was restored. You may want to add (or remove) the `reversed` keyword when you're iterating on `date_list` in a template:

```
{% for date in date_list reversed %}
```

`ArchiveIndexView` still provides a `date_list` in descending order.

## Context in TemplateView

For consistency with the design of the other generic views, `TemplateView` no longer passes a `params` dictionary into the context, instead passing the variables from the `URLconf` directly into the context.

## Non-form data in HTTP requests

`request.POST` will no longer include data posted via HTTP requests with non form-specific content-types in the header. In prior versions, data posted with content-types other than `multipart/form-data` or `application/x-www-form-urlencoded` would still end up represented in the `request.POST` attribute. Developers wishing to access the raw POST data for these cases, should use the `request.body` attribute instead.

## request\_finished signal

Django used to send the `request_finished` signal as soon as the view function returned a response. This interacted badly with *streaming responses* that delay content generation.

This signal is now sent after the content is fully consumed by the WSGI gateway. This might be backwards incompatible if you rely on the signal being fired before sending the response content to the client. If you do, you should consider using *middleware* instead.

---

**Note:** Some WSGI servers and middleware do not always call `close` on the response object after handling a request, most notably uWSGI prior to 1.2.6 and Sentry's error reporting middleware up to 2.0.7. In those cases the `request_finished` signal isn't sent at all. This can result in idle connections to database and memcache servers.

---

## OPTIONS, PUT and DELETE requests in the test client

Unlike GET and POST, these HTTP methods aren't implemented by web browsers. Rather, they're used in APIs, which transfer data in various formats such as JSON or XML. Since such requests may contain arbitrary data, Django doesn't attempt to decode their body.

However, the test client used to build a query string for OPTIONS and DELETE requests like for GET, and a request body for PUT requests like for POST. This encoding was arbitrary and inconsistent with Django's behavior when it receives the requests, so it was removed in Django 1.5.

If you were using the `data` parameter in an OPTIONS or a DELETE request, you must convert it to a query string and append it to the `path` parameter.

If you were using the `data` parameter in a PUT request without a `content_type`, you must encode your data before passing it to the test client and set the `content_type` argument.

## System version of `simplejson` no longer used

As explained below, Django 1.5 deprecates `django.utils.simplejson` in favor of Python 2.6's built-in `json` module. In theory, this change is harmless. Unfortunately, because of incompatibilities between versions of `simplejson`, it may trigger errors in some circumstances.

JSON-related features in Django 1.4 always used `django.utils.simplejson`. This module was actually:

- A system version of `simplejson`, if one was available (ie. `import simplejson` works), if it was more recent than Django's built-in copy or it had the C speedups, or
- The `json` module from the standard library, if it was available (ie. Python 2.6 or greater), or
- A built-in copy of version 2.0.7 of `simplejson`.

In Django 1.5, those features use Python's `json` module, which is based on version 2.0.9 of `simplejson`.

There are no known incompatibilities between Django's copy of version 2.0.7 and Python's copy of version 2.0.9. However, there are some incompatibilities between other versions of `simplejson`:

- While the `simplejson` API is documented as always returning unicode strings, the optional C implementation can return a byte string. This was fixed in Python 2.7.
- `simplejson.JSONEncoder` gained a `namedtuple_as_object` keyword argument in version 2.2.

More information on these incompatibilities is available in [ticket #18023](#).

The net result is that, if you have installed `simplejson` and your code uses Django's serialization internals directly – for instance `django.core.serializers.json.DjangoJSONEncoder`, the switch from `simplejson` to `json` could break your code. (In general, changes to internals aren't documented; we're making an exception here.)

At this point, the maintainers of Django believe that using `json` from the standard library offers the strongest guarantee of backwards-compatibility. They recommend to use it from now on.

## String types of hasher method parameters

If you have written a *custom password hasher*, your `encode()`, `verify()` or `safe_summary()` methods should accept Unicode parameters (`password`, `salt` or `encoded`). If any of the hashing methods need byte strings, you can use the `force_bytes()` utility to encode the strings.

## Validation of `previous_page_number` and `next_page_number`

When using *object pagination*, the `previous_page_number()` and `next_page_number()` methods of the `Page` object did not check if the returned number was inside the existing page range. It does check it now and raises an `InvalidPage` exception when the number is either too low or too high.

## Behavior of autocommit database option on PostgreSQL changed

PostgreSQL's autocommit option didn't work as advertised previously. It did work for single transaction block, but after the first block was left the autocommit behavior was never restored. This bug is now fixed in 1.5. While this is only a bug fix, it is worth checking your applications behavior if you are using PostgreSQL together with the autocommit option.

## Session not saved on 500 responses

Django's session middleware will skip saving the session data if the response's status code is 500.

## Email checks on failed admin login

Prior to Django 1.5, if you attempted to log into the admin interface and mistakenly used your email address instead of your username, the admin interface would provide a warning advising that your email address was not your username. In Django 1.5, the introduction of *custom user models* has required the removal of this warning. This doesn't change the login behavior of the admin site; it only affects the warning message that is displayed under one particular mode of login failure.

## Changes in tests execution

Some changes have been introduced in the execution of tests that might be backward-incompatible for some testing setups:

### Database flushing in `django.test.TransactionTestCase`

Previously, the test database was truncated *before* each test run in a *TransactionTestCase*.

In order to be able to run unit tests in any order and to make sure they are always isolated from each other, *TransactionTestCase* will now reset the database *after* each test run instead.

### No more implicit DB sequences reset

*TransactionTestCase* tests used to reset primary key sequences automatically together with the database flushing actions described above.

This has been changed so no sequences are implicitly reset. This can cause *TransactionTestCase* tests that depend on hard-coded primary key values to break.

The new *reset\_sequences* attribute can be used to force the old behavior for *TransactionTestCase* that might need it.

## Ordering of tests

In order to make sure all *TestCase* code starts with a clean database, tests are now executed in the following order:

- First, all unittests (including *unittest.TestCase*, *SimpleTestCase*, *TestCase* and *TransactionTestCase*) are run with no particular ordering guaranteed nor enforced among them.
- Then any other tests (e.g. doctests) that may alter the database without restoring it to its original state are run.

This should not cause any problems unless you have existing doctests which assume a *TransactionTestCase* executed earlier left some database state behind or unit tests that rely on some form of state being preserved after the execution of other tests. Such tests are already very fragile, and must now be changed to be able to run independently.

### ***cleaned\_data* dictionary kept for invalid forms**

The *cleaned\_data* dictionary is now always present after form validation. When the form doesn't validate, it contains only the fields that passed validation. You should test the success of the validation with the *is\_valid()* method and not with the presence or absence of the *cleaned\_data* attribute on the form.

### **Behavior of *syncdb* with multiple databases**

*syncdb* now queries the database routers to determine if content types (when *contenttypes* is enabled) and permissions (when *auth* is enabled) should be created in the target database. Previously, it created them in the default database, even when another database was specified with the `--database` option.

If you use *syncdb* on multiple databases, you should ensure that your routers allow synchronizing content types and permissions to only one of them. See the docs on the *behavior of contrib apps with multiple databases* for more information.

### **XML deserializer will not parse documents with a DTD**

In order to prevent exposure to denial-of-service attacks related to external entity references and entity expansion, the XML model deserializer now refuses to parse XML documents containing a DTD (DOCTYPE definition). Since the XML serializer does not output a DTD, this will not impact typical usage, only cases where custom-created XML documents are passed to Django's model deserializer.

### **Formsets default *max\_num***

A (default) value of `None` for the *max\_num* argument to a formset factory no longer defaults to allowing any number of forms in the formset. Instead, in order to prevent memory-exhaustion attacks, it now defaults to a limit of 1000 forms. This limit can be raised by explicitly setting a higher value for *max\_num*.

### **Miscellaneous**

- *django.forms.ModelFormMultipleChoiceField* now returns an empty `QuerySet` as the empty value instead of an empty list.
- *int\_to\_base36()* properly raises a `TypeError` instead of `ValueError` for non-integer inputs.
- The *slugify* template filter is now available as a standard python function at *django.utils.text.slugify()*. Similarly, *remove\_tags* is available at *django.utils.html.remove\_tags()*.
- Uploaded files are no longer created as executable by default. If you need them to be executable change `FILE_UPLOAD_PERMISSIONS` to your needs. The new default value is `0o666` (octal) and the current `umask` value is first masked out.
- The *F expressions* supported bitwise operators by `&` and `|`. These operators are now available using `.bitand()` and `.bitor()` instead. The removal of `&` and `|` was done to be consistent with *Q() expressions* and `QuerySet` combining where the operators are used as boolean AND and OR operators.
- In a *filter()* call, when *F expressions* contained lookups spanning multi-valued relations, they didn't always reuse the same relations as other lookups along the same chain. This was changed, and now *F()* expressions will always use the same relations as other lookups within the same *filter()* call.
- The *csrf\_token* template tag is no longer enclosed in a `div`. If you need HTML validation against pre-HTML5 Strict DTDs, you should add a `div` around it in your pages.

- The template tags library `adminmedia`, which only contained the deprecated template tag `{% admin_media_prefix %}`, was removed. Attempting to load it with `{% load adminmedia %}` will fail. If your templates still contain that line you must remove it.
- Because of an implementation oversight, it was possible to use `django.contrib.redirects` without enabling `django.contrib.sites`. This isn't allowed any longer. If you're using `django.contrib.redirects`, make sure `INSTALLED_APPS` contains `django.contrib.sites`.
- `BoundField.label_tag` now escapes its `contents` argument. To avoid the HTML escaping, use `django.utils.safestring.mark_safe()` on the argument before passing it.
- Accessing reverse one-to-one relations fetched via `select_related()` now raises `DoesNotExist` instead of returning `None`.

## Features deprecated in 1.5

### `django.contrib.localflavor`

The `localflavor` contrib app has been split into separate packages. `django.contrib.localflavor` itself will be removed in Django 1.6, after an accelerated deprecation.

The new packages are available on GitHub. The core team cannot efficiently maintain these packages in the long term — it spans just a dozen countries at this time; similar to translations, maintenance will be handed over to interested members of the community.

### `django.contrib.markup`

The `markup` contrib module has been deprecated and will follow an accelerated deprecation schedule. Direct use of Python markup libraries or 3rd party tag libraries is preferred to Django maintaining this functionality in the framework.

### `AUTH_PROFILE_MODULE`

With the introduction of *custom user models*, there is no longer any need for a built-in mechanism to store user profile data.

You can still define user profiles models that have a one-to-one relation with the `User` model - in fact, for many applications needing to associate data with a `User` account, this will be an appropriate design pattern to follow. However, the `AUTH_PROFILE_MODULE` setting, and the `django.contrib.auth.models.User.get_profile()` method for accessing the user profile model, should not be used any longer.

## Streaming behavior of `HttpResponse`

Django 1.5 deprecates the ability to stream a response by passing an iterator to `HttpResponse`. If you rely on this behavior, switch to `StreamingHttpResponse`. See *Explicit support for streaming responses* above.

In Django 1.7 and above, the iterator will be consumed immediately by `HttpResponse`.

### `django.utils.simplejson`

Since Django 1.5 drops support for Python 2.5, we can now rely on the `json` module being available in Python's standard library, so we've removed our own copy of `simplejson`. You should now import `json` instead of `django.utils.simplejson`.

Unfortunately, this change might have unwanted side-effects, because of incompatibilities between versions of `simplejson` – see the *backwards-incompatible changes* section. If you rely on features added to `simplejson` after it became Python's `json`, you should import `simplejson` explicitly.

### `django.utils.encoding.StrAndUnicode`

The `django.utils.encoding.StrAndUnicode` mix-in has been deprecated. Define a `__str__` method and apply the `python_2_unicode_compatible()` decorator instead.

### `django.utils.itercompat.product`

The `django.utils.itercompat.product` function has been deprecated. Use the built-in `itertools.product()` instead.

### cleanup management command

The `cleanup` management command has been deprecated and replaced by `clearsessions`.

### `daily_cleanup.py` script

The undocumented `daily_cleanup.py` script has been deprecated. Use the `clearsessions` management command instead.

### depth keyword argument in `select_related`

The `depth` keyword argument in `select_related()` has been deprecated. You should use field names instead.

## 9.1.7 1.4 release

### Django 1.4.22 release notes

*August 18, 2015*

Django 1.4.22 fixes a security issue in 1.4.21.

It also fixes support with pip 7+ by disabling wheel support. Older versions of 1.4 would silently build a broken wheel when installed with those versions of pip.

## Denial-of-service possibility in `logout ()` view by filling session store

Previously, a session could be created when anonymously accessing the `django.contrib.auth.views.logout ()` view (provided it wasn't decorated with `login_required ()` as done in the admin). This could allow an attacker to easily create many new session records by sending repeated requests, potentially filling up the session store or causing other users' session records to be evicted.

The `SessionMiddleware` has been modified to no longer create empty session records, including when `SESSION_SAVE_EVERY_REQUEST` is active.

Additionally, the `contrib.sessions.backends.base.SessionBase.flush ()` and `cache_db.SessionStore.flush ()` methods have been modified to avoid creating a new empty session. Maintainers of third-party session backends should check if the same vulnerability is present in their backend and correct it if so.

## Django 1.4.21 release notes

July 8, 2015

Django 1.4.21 fixes several security issues in 1.4.20.

### Denial-of-service possibility by filling session store

In previous versions of Django, the session backends created a new empty record in the session storage anytime `request.session` was accessed and there was a session key provided in the request cookies that didn't already have a session record. This could allow an attacker to easily create many new session records simply by sending repeated requests with unknown session keys, potentially filling up the session store or causing other users' session records to be evicted.

The built-in session backends now create a session record only if the session is actually modified; empty session records are not created. Thus this potential DoS is now only possible if the site chooses to expose a session-modifying view to anonymous users.

As each built-in session backend was fixed separately (rather than a fix in the core sessions framework), maintainers of third-party session backends should check whether the same vulnerability is present in their backend and correct it if so.

### Header injection possibility since validators accept newlines in input

Some of Django's built-in validators (`EmailValidator`, most seriously) didn't prohibit newline characters (due to the usage of `$` instead of `\Z` in the regular expressions). If you use values with newlines in HTTP response or email headers, you can suffer from header injection attacks. Django itself isn't vulnerable because `HttpResponse` and the mail sending utilities in `django.core.mail` prohibit newlines in HTTP and SMTP headers, respectively. While the validators have been fixed in Django, if you're creating HTTP responses or email messages in other ways, it's a good idea to ensure that those methods prohibit newlines as well. You might also want to validate that any existing data in your application doesn't contain unexpected newlines.

`validate_ipv4_address ()`, `validate_slug ()`, and `URLValidator` and their usage in the corresponding form fields `GenericIPAddressField`, `IPAddressField`, `SlugField`, and `URLField` are also affected.

The undocumented, internally unused `validate_integer ()` function is now stricter as it validates using a regular expression instead of simply casting the value using `int ()` and checking if an exception was raised.

## Django 1.4.20 release notes

March 18, 2015

Django 1.4.20 fixes one security issue in 1.4.19.

### Mitigated possible XSS attack via user-supplied redirect URLs

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()` and `isln`) to redirect the user to an “on success” URL. The security checks for these redirects (namely `django.utils.http.is_safe_url()`) accepted URLs with leading control characters and so considered URLs like `\x08javascript:... safe`. This issue doesn’t affect Django currently, since we only put this URL into the `Location` response header and browsers seem to ignore JavaScript there. Browsers we tested also treat URLs prefixed with control characters such as `%08//example.com` as relative paths so redirection to an unsafe target isn’t a problem either.

However, if a developer relies on `is_safe_url()` to provide safe redirect targets and puts such a URL into a link, they could suffer from an XSS attack as some browsers such as Google Chrome ignore control characters at the start of a URL in an anchor `href`.

## Django 1.4.19 release notes

January 27, 2015

Django 1.4.19 fixes a regression in the 1.4.18 security release.

### Bugfixes

- `GZipMiddleware` now supports streaming responses. As part of the 1.4.18 security release, the `django.views.static.serve()` function was altered to stream the files it serves. Unfortunately, the `GZipMiddleware` consumed the stream prematurely and prevented files from being served properly (#24158).

## Django 1.4.18 release notes

January 13, 2015

Django 1.4.18 fixes several security issues in 1.4.17 as well as a regression on Python 2.5 in the 1.4.17 release.

### WSGI header spoofing via underscore/dash conflation

When HTTP headers are placed into the WSGI environ, they are normalized by converting to uppercase, converting all dashes to underscores, and prepending `HTTP_`. For instance, a header `X-Auth-User` would become `HTTP_X_AUTH_USER` in the WSGI environ (and thus also in Django’s `request.META` dictionary).

Unfortunately, this means that the WSGI environ cannot distinguish between headers containing dashes and headers containing underscores: `X-Auth-User` and `X-Auth_User` both become `HTTP_X_AUTH_USER`. This means that if a header is used in a security-sensitive way (for instance, passing authentication information along from a front-end proxy), even if the proxy carefully strips any incoming value for `X-Auth-User`, an attacker may be able to provide an `X-Auth_User` header (with underscore) and bypass this protection.

In order to prevent such attacks, both Nginx and Apache 2.4+ strip all headers containing underscores from incoming requests by default. Django’s built-in development server now does the same. Django’s development server is not

recommended for production use, but matching the behavior of common production servers reduces the surface area for behavior changes during deployment.

### Mitigated possible XSS attack via user-supplied redirect URLs

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()` and `isbn`) to redirect the user to an “on success” URL. The security checks for these redirects (namely `django.utils.http.is_safe_url()`) didn’t strip leading whitespace on the tested URL and as such considered URLs like `\njavascript:... safe`. If a developer relied on `is_safe_url()` to provide safe redirect targets and put such a URL into a link, they could suffer from a XSS attack. This bug doesn’t affect Django currently, since we only put this URL into the `Location` response header and browsers seem to ignore JavaScript there.

### Denial-of-service attack against `django.views.static.serve`

In older versions of Django, the `django.views.static.serve()` view read the files it served one line at a time. Therefore, a big file with no newlines would result in memory usage equal to the size of that file. An attacker could exploit this and launch a denial-of-service attack by simultaneously requesting many large files. This view now reads the file in chunks to prevent large memory usage.

Note, however, that this view has always carried a warning that it is not hardened for production use and should be used only as a development aid. Now may be a good time to audit your project and serve your files in production using a real front-end web server if you are not doing so.

### Bugfixes

- To maintain compatibility with Python 2.5, Django’s vendored version of six, `django.utils.six`, has been downgraded to 1.8.0 which is the last version to support Python 2.5.

### Django 1.4.17 release notes

*January 2, 2015*

Django 1.4.17 fixes a regression in the 1.4.14 security release.

Additionally, Django’s vendored version of six, `django.utils.six`, has been upgraded to the latest release (1.9.0).

### Bugfixes

- Fixed a regression with dynamically generated inlines and allowed field references in the admin ([#23754](#)).

### Django 1.4.16 release notes

*October 22, 2014*

Django 1.4.16 fixes a couple regressions in the 1.4.14 security release and a bug preventing the use of some GEOS versions with GeoDjango.

## Bugfixes

- Allowed related many-to-many fields to be referenced in the admin (#23604).
- Allowed inline and hidden references to admin fields (#23431).
- Fixed parsing of the GEOS version string (#20036).

## Django 1.4.15 release notes

*September 2, 2014*

Django 1.4.15 fixes a regression in the 1.4.14 security release.

## Bugfixes

- Allowed inherited and m2m fields to be referenced in the admin (#22486)

## Django 1.4.14 release notes

*August 20, 2014*

Django 1.4.14 fixes several security issues in 1.4.13.

### **`reverse ()` could generate URLs pointing to other hosts**

In certain situations, URL reversing could generate scheme-relative URLs (URLs starting with two slashes), which could unexpectedly redirect a user to a different host. An attacker could exploit this, for example, by redirecting users to a phishing site designed to ask for user's passwords.

To remedy this, URL reversing now ensures that no URL starts with two slashes (`//`), replacing the second slash with its URL encoded counterpart (`%2F`). This approach ensures that semantics stay the same, while making the URL relative to the domain and not to the scheme.

### **File upload denial-of-service**

Before this release, Django's file upload handling in its default configuration may degrade to producing a huge number of `os.stat ()` system calls when a duplicate filename is uploaded. Since `stat ()` may invoke IO, this may produce a huge data-dependent slowdown that slowly worsens over time. The net result is that given enough time, a user with the ability to upload files can cause poor performance in the upload handler, eventually causing it to become very slow simply by uploading 0-byte files. At this point, even a slow network connection and few HTTP requests would be all that is necessary to make a site unavailable.

We've remedied the issue by changing the algorithm for generating file names if a file with the uploaded name already exists. `Storage.get_available_name ()` now appends an underscore plus a random 7 character alphanumeric string (e.g. `"_x3a1gho"`), rather than iterating through an underscore followed by a number (e.g. `"_1"`, `"_2"`, etc.).

### RemoteUserMiddleware session hijacking

When using the `RemoteUserMiddleware` and the `RemoteUserBackend`, a change to the `REMOTE_USER` header between requests without an intervening logout could result in the prior user's session being co-opted by the subsequent user. The middleware now logs the user out on a failed login attempt.

### Data leakage via query string manipulation in `contrib.admin`

In older versions of Django it was possible to reveal any field's data by modifying the "popup" and "to\_field" parameters of the query string on an admin change form page. For example, requesting a URL like `/admin/auth/user/?pop=1&t=password` and viewing the page's HTML allowed viewing the password hash of each user. While the admin requires users to have permissions to view the change form pages in the first place, this could leak data if you rely on users having access to view only certain fields on a model.

To address the issue, an exception will now be raised if a `to_field` value that isn't a related field to a model that has been registered with the admin is specified.

### Django 1.4.13 release notes

May 14, 2014

Django 1.4.13 fixes two security issues in 1.4.12.

### Caches may incorrectly be allowed to store and serve private data

In certain situations, Django may allow caches to store private data related to a particular session and then serve that data to requests with a different session, or no session at all. This can lead to information disclosure and can be a vector for cache poisoning.

When using Django sessions, Django will set a `Vary: Cookie` header to ensure caches do not serve cached data to requests from other sessions. However, older versions of Internet Explorer (most likely only Internet Explorer 6, and Internet Explorer 7 if run on Windows XP or Windows Server 2003) are unable to handle the `Vary` header in combination with many content types. Therefore, Django would remove the header if the request was made by Internet Explorer.

To remedy this, the special behavior for these older Internet Explorer versions has been removed, and the `Vary` header is no longer stripped from the response. In addition, modifications to the `Cache-Control` header for all Internet Explorer requests with a `Content-Disposition` header have also been removed as they were found to have similar issues.

### Malformed redirect URLs from user input not correctly validated

The validation for redirects did not correctly validate some malformed URLs, which are accepted by some browsers. This allows a user to be redirected to an unsafe URL unexpectedly.

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()`, `django.contrib.comments`, and `ii8n`) to redirect the user to an "on success" URL. The security checks for these redirects (namely `django.utils.http.is_safe_url()`) did not correctly validate some malformed URLs, such as `http:\\djangoproject.com`, which are accepted by some browsers with more liberal URL parsing.

To remedy this, the validation in `is_safe_url()` has been tightened to be able to handle and correctly validate these malformed URLs.

## Django 1.4.12 release notes

April 28, 2014

Django 1.4.12 fixes a regression in the 1.4.11 security release.

### Bugfixes

- Restored the ability to `reverse()` views created using `functools.partial()` (#22486).

## Django 1.4.11 release notes

April 21, 2014

Django 1.4.11 fixes three security issues in 1.4.10. Additionally, Django’s vendored version of six, `django.utils.six`, has been upgraded to the latest release (1.6.1).

### Unexpected code execution using `reverse()`

Django’s URL handling is based on a mapping of regex patterns (representing the URLs) to callable views, and Django’s own processing consists of matching a requested URL against those patterns to determine the appropriate view to invoke.

Django also provides a convenience function – `reverse()` – which performs this process in the opposite direction. The `reverse()` function takes information about a view and returns a URL which would invoke that view. Use of `reverse()` is encouraged for application developers, as the output of `reverse()` is always based on the current URL patterns, meaning developers do not need to change other code when making changes to URLs.

One argument signature for `reverse()` is to pass a dotted Python path to the desired view. In this situation, Django will import the module indicated by that dotted path as part of generating the resulting URL. If such a module has import-time side effects, those side effects will occur.

Thus it is possible for an attacker to cause unexpected code execution, given the following conditions:

1. One or more views are present which construct a URL based on user input (commonly, a “next” parameter in a querystring indicating where to redirect upon successful completion of an action).
2. One or more modules are known to an attacker to exist on the server’s Python import path, which perform code execution with side effects on importing.

To remedy this, `reverse()` will now only accept and import dotted paths based on the view-containing modules listed in the project’s *URL pattern configuration*, so as to ensure that only modules the developer intended to be imported in this fashion can or will be imported.

### Caching of anonymous pages could reveal CSRF token

Django includes both a *caching framework* and a system for *preventing cross-site request forgery (CSRF) attacks*. The CSRF-protection system is based on a random nonce sent to the client in a cookie which must be sent by the client on future requests and, in forms, a hidden value which must be submitted back with the form.

The caching framework includes an option to cache responses to anonymous (i.e., unauthenticated) clients.

When the first anonymous request to a given page is by a client which did not have a CSRF cookie, the cache framework will also cache the CSRF cookie and serve the same nonce to other anonymous clients who do not have a CSRF

cookie. This can allow an attacker to obtain a valid CSRF cookie value and perform attacks which bypass the check for the cookie.

To remedy this, the caching framework will no longer cache such responses. The heuristic for this will be:

1. If the incoming request did not submit any cookies, and
2. If the response did send one or more cookies, and
3. If the `Vary: Cookie` header is set on the response, then the response will not be cached.

## MySQL typecasting

The MySQL database is known to “typecast” on certain queries; for example, when querying a table which contains string values, but using a query which filters based on an integer value, MySQL will first silently coerce the strings to integers and return a result based on that.

If a query is performed without first converting values to the appropriate type, this can produce unexpected results, similar to what would occur if the query itself had been manipulated.

Django’s model field classes are aware of their own types and most such classes perform explicit conversion of query arguments to the correct database-level type before querying. However, three model field classes did not correctly convert their arguments:

- `FilePathField`
- `GenericIPAddressField`
- `IPAddressField`

These three fields have been updated to convert their arguments to the correct types before querying.

Additionally, developers of custom model fields are now warned via documentation to ensure their custom field classes will perform appropriate type conversions, and users of the `raw()` and `extra()` query methods – which allow the developer to supply raw SQL or SQL fragments – will be advised to ensure they perform appropriate manual type conversions prior to executing queries.

## Django 1.4.10 release notes

*November 6, 2013*

Django 1.4.10 fixes a Python-compatibility bug in the 1.4 series.

## Python compatibility

Django 1.4.9 inadvertently introduced issues with Python 2.5 compatibility. Django 1.4.10 restores Python 2.5 compatibility. This was issue #21362 in Django’s Trac.

## Django 1.4.9 release notes

*October 23, 2013*

Django 1.4.9 fixes a security-related bug in the 1.4 series and one other data corruption bug.

## Readdressed denial-of-service via password hashers

Django 1.4.8 imposes a 4096-byte limit on passwords in order to mitigate a denial-of-service attack through submission of bogus but extremely large passwords. In Django 1.4.9, we've reverted this change and instead improved the speed of our PBKDF2 algorithm by not rehashing the key on every iteration.

## Bugfixes

- Fixed a data corruption bug with `datetime_safe.datetime.combine` (#21256).

## Django 1.4.8 release notes

*September 14, 2013*

Django 1.4.8 fixes two security issues present in previous Django releases in the 1.4 series.

### Denial-of-service via password hashers

In previous versions of Django, no limit was imposed on the plaintext length of a password. This allowed a denial-of-service attack through submission of bogus but extremely large passwords, tying up server resources performing the (expensive, and increasingly expensive with the length of the password) calculation of the corresponding hash.

As of 1.4.8, Django's authentication framework imposes a 4096-byte limit on passwords and will fail authentication with any submitted password of greater length.

### Corrected usage of `sensitive_post_parameters()` in `django.contrib.auth`'s admin

The decoration of the `add_view` and `user_change_password` user admin views with `sensitive_post_parameters()` did not include `method_decorator()` (required since the views are methods) resulting in the decorator not being properly applied. This usage has been fixed and `sensitive_post_parameters()` will now throw an exception if it's improperly used.

## Django 1.4.7 release notes

*September 10, 2013*

Django 1.4.7 fixes one security issue present in previous Django releases in the 1.4 series.

### Directory traversal vulnerability in `ssi` template tag

In previous versions of Django it was possible to bypass the `ALLOWED_INCLUDE_ROOTS` setting used for security with the `ssi` template tag by specifying a relative path that starts with one of the allowed roots. For example, if `ALLOWED_INCLUDE_ROOTS = ("/var/www",)` the following would be possible:

```
{% ssi "/var/www/../../../../etc/passwd" %}
```

In practice this is not a very common problem, as it would require the template author to put the `ssi` file in a user-controlled variable, but it's possible in principle.

## Django 1.4.6 release notes

August 13, 2013

Django 1.4.6 fixes one security issue present in previous Django releases in the 1.4 series, as well as one other bug.

This is the sixth bugfix/security release in the Django 1.4 series.

### Mitigated possible XSS attack via user-supplied redirect URLs

Django relies on user input in some cases (e.g. `django.contrib.auth.views.login()`, `django.contrib.comments`, and *118n*) to redirect the user to an “on success” URL. The security checks for these redirects (namely `django.utils.http.is_safe_url()`) didn’t check if the scheme is `http(s)` and as such allowed `javascript:...` URLs to be entered. If a developer relied on `is_safe_url()` to provide safe redirect targets and put such a URL into a link, they could suffer from a XSS attack. This bug doesn’t affect Django currently, since we only put this URL into the `Location` response header and browsers seem to ignore JavaScript there.

### Bugfixes

- Fixed an obscure bug with the `override_settings()` decorator. If you hit an `AttributeError: 'Settings' object has no attribute '_original_allowed_hosts'` exception, it’s probably fixed (#20636).

## Django 1.4.5 release notes

February 20, 2013

Django 1.4.5 corrects a packaging problem with yesterday’s *1.4.4 release*.

The release contained stray `.pyc` files that caused “bad magic number” errors when running with some versions of Python. This release corrects this, and also fixes a bad documentation link in the project template `settings.py` file generated by `manage.py startproject`.

## Django 1.4.4 release notes

February 19, 2013

Django 1.4.4 fixes four security issues present in previous Django releases in the 1.4 series, as well as several other bugs and numerous documentation improvements.

This is the fourth bugfix/security release in the Django 1.4 series.

### Host header poisoning

Some parts of Django – independent of end-user-written applications – make use of full URLs, including domain name, which are generated from the HTTP Host header. Django’s documentation has for some time contained notes advising users on how to configure Web servers to ensure that only valid Host headers can reach the Django application. However, it has been reported to us that even with the recommended Web server configurations there are still techniques available for tricking many common Web servers into supplying the application with an incorrect and possibly malicious Host header.

For this reason, Django 1.4.4 adds a new setting, `ALLOWED_HOSTS`, containing an explicit list of valid host/domain names for this site. A request with a Host header not matching an entry in this list will raise

`SuspiciousOperation` if `request.get_host()` is called. For full details see the documentation for the `ALLOWED_HOSTS` setting.

The default value for this setting in Django 1.4.4 is `[ '*' ]` (matching any host), for backwards-compatibility, but we strongly encourage all sites to set a more restrictive value.

This host validation is disabled when `DEBUG` is `True` or when running tests.

## XML deserialization

The XML parser in the Python standard library is vulnerable to a number of attacks via external entities and entity expansion. Django uses this parser for deserializing XML-formatted database fixtures. This deserializer is not intended for use with untrusted data, but in order to err on the side of safety in Django 1.4.4 the XML deserializer refuses to parse an XML document with a DTD (DOCTYPE definition), which closes off these attack avenues.

These issues in the Python standard library are CVE-2013-1664 and CVE-2013-1665. More information available from the [Python security team](#).

Django's XML serializer does not create documents with a DTD, so this should not cause any issues with the typical round-trip from `dumpdata` to `loaddata`, but if you feed your own XML documents to the `loaddata` management command, you will need to ensure they do not contain a DTD.

## Formset memory exhaustion

Previous versions of Django did not validate or limit the form-count data provided by the client in a formset's management form, making it possible to exhaust a server's available memory by forcing it to create very large numbers of forms.

In Django 1.4.4, all formsets have a strictly-enforced maximum number of forms (1000 by default, though it can be set higher via the `max_num` formset factory argument).

## Admin history view information leakage

In previous versions of Django, an admin user without change permission on a model could still view the unicode representation of instances via their admin history log. Django 1.4.4 now limits the admin history log view for an object to users with change permission for that model.

## Other bugfixes and changes

- Prevented transaction state from leaking from one request to the next (#19707).
- Changed an SQL command syntax to be MySQL 4 compatible (#19702).
- Added backwards-compatibility with old unsalted MD5 passwords (#18144).
- Numerous documentation improvements and fixes.

## Django 1.4.3 release notes

*December 10, 2012*

Django 1.4.3 addresses two security issues present in previous Django releases in the 1.4 series.

Please be aware that this security release is slightly different from previous ones. Both issues addressed here have been dealt with in prior security updates to Django. In one case, we have received ongoing reports of problems, and in the other we've chosen to take further steps to tighten up Django's code in response to independent discovery of potential problems from multiple sources.

## Host header poisoning

Several earlier Django security releases focused on the issue of poisoning the HTTP Host header, causing Django to generate URLs pointing to arbitrary, potentially-malicious domains.

In response to further input received and reports of continuing issues following the previous release, we're taking additional steps to tighten Host header validation. Rather than attempt to accommodate all features HTTP supports here, Django's Host header validation attempts to support a smaller, but far more common, subset:

- Hostnames must consist of characters `[A-Za-z0-9]` plus hyphen ('-') or dot ('.').
- IP addresses – both IPv4 and IPv6 – are permitted.
- Port, if specified, is numeric.

Any deviation from this will now be rejected, raising the exception `django.core.exceptions.SuspiciousOperation`.

## Redirect poisoning

Also following up on a previous issue: in July of this year, we made changes to Django's HTTP redirect classes, performing additional validation of the scheme of the URL to redirect to (since, both within Django's own supplied applications and many third-party applications, accepting a user-supplied redirect target is a common pattern).

Since then, two independent audits of the code turned up further potential problems. So, similar to the Host-header issue, we are taking steps to provide tighter validation in response to reported problems (primarily with third-party applications, but to a certain extent also within Django itself). This comes in two parts:

1. A new utility function, `django.utils.http.is_safe_url`, is added; this function takes a URL and a hostname, and checks that the URL is either relative, or if absolute matches the supplied hostname. This function is intended for use whenever user-supplied redirect targets are accepted, to ensure that such redirects cannot lead to arbitrary third-party sites.
2. All of Django's own built-in views – primarily in the authentication system – which allow user-supplied redirect targets now use `is_safe_url` to validate the supplied URL.

## Django 1.4.2 release notes

*October 17, 2012*

This is the second security release in the Django 1.4 series.

## Host header poisoning

Some parts of Django – independent of end-user-written applications – make use of full URLs, including domain name, which are generated from the HTTP Host header. Some attacks against this are beyond Django's ability to control, and require the web server to be properly configured; Django's documentation has for some time contained notes advising users on such configuration.

Django’s own built-in parsing of the Host header is, however, still vulnerable, as was reported to us recently. The Host header parsing in Django 1.3.3 and Django 1.4.1 – specifically, `django.http.HttpRequest.get_host()` – was incorrectly handling username/password information in the header. Thus, for example, the following Host header would be accepted by Django when running on “validsite.com”:

```
Host: validsite.com:random@evilsite.com
```

Using this, an attacker can cause parts of Django – particularly the password-reset mechanism – to generate and display arbitrary URLs to users.

To remedy this, the parsing in `HttpRequest.get_host()` is being modified; Host headers which contain potentially dangerous content (such as username/password pairs) now raise the exception `django.core.exceptions.SuspiciousOperation`.

Details of this issue were initially posted online as a [security advisory](#).

### Backwards incompatible changes

- The newly introduced `GenericIPAddressField` constructor arguments have been adapted to match those of all other model fields. The first two keyword arguments are now `verbose_name` and `name`.

### Other bugfixes and changes

- Subclass `HTMLParser` only for appropriate Python versions (#18239).
- Added `batch_size` argument to `qs.bulk_create()` (#17788).
- Fixed a small regression in the admin filters where wrongly formatted dates passed as url parameters caused an unhandled `ValidationError` (#18530).
- Fixed an endless loop bug when accessing permissions in templates (#18979)
- Fixed some Python 2.5 compatibility issues
- Fixed an issue with quoted filenames in Content-Disposition header (#19006)
- Made the context option in `trans` and `blocktrans` tags accept literals wrapped in single quotes (#18881).
- Numerous documentation improvements and fixes.

### Django 1.4.1 release notes

July 30, 2012

This is the first security release in the Django 1.4 series, fixing several security issues in Django 1.4. Django 1.4.1 is a recommended upgrade for all users of Django 1.4.

For a full list of issues addressed in this release, see the [security advisory](#).

### Django 1.4 release notes

March 23, 2012

Welcome to Django 1.4!

These release notes cover the *new features*, as well as some *backwards incompatible changes* you’ll want to be aware of when upgrading from Django 1.3 or older versions. We’ve also dropped some features, which are detailed in *our deprecation plan*, and we’ve *begun the deprecation process for some features*.

## Overview

The biggest new feature in Django 1.4 is *support for time zones* when handling date/times. When enabled, this Django will store date/times in UTC, use timezone-aware objects internally, and translate them to users' local timezones for display.

If you're upgrading an existing project to Django 1.4, switching to the timezone aware mode may take some care: the new mode disallows some rather sloppy behavior that used to be accepted. We encourage anyone who's upgrading to check out the *timezone migration guide* and the *timezone FAQ* for useful pointers.

Other notable new features in Django 1.4 include:

- A number of ORM improvements, including *SELECT FOR UPDATE support*, the ability to *bulk insert* large datasets for improved performance, and *QuerySet.prefetch\_related*, a method to batch-load related objects in areas where *select\_related()* doesn't work.
- Some nice security additions, including *improved password hashing* (featuring PBKDF2 and bcrypt support), new *tools for cryptographic signing*, several *CSRF improvements*, and *simple clickjacking protection*.
- An *updated default project layout and manage.py* that removes the "magic" from prior versions. And for those who don't like the new layout, you can use *custom project and app templates* instead!
- *Support for in-browser testing frameworks* (like Selenium).
- ... and a whole lot more; *see below!*

Wherever possible we try to introduce new features in a backwards-compatible manner per *our API stability policy* policy. However, as with previous releases, Django 1.4 ships with some minor *backwards incompatible changes*; people upgrading from previous versions of Django should read that list carefully.

## Python compatibility

Django 1.4 has dropped support for Python 2.4. Python 2.5 is now the minimum required Python version. Django is tested and supported on Python 2.5, 2.6 and 2.7.

This change should affect only a small number of Django users, as most operating-system vendors today are shipping Python 2.5 or newer as their default version. If you're still using Python 2.4, however, you'll need to stick to Django 1.3 until you can upgrade. Per *our support policy*, Django 1.3 will continue to receive security support until the release of Django 1.5.

Django does not support Python 3.x at this time. At some point before the release of Django 1.4, we plan to publish a document outlining our full timeline for deprecating Python 2.x and moving to Python 3.x.

## What's new in Django 1.4

### Support for time zones

In previous versions, Django used "naive" date/times (that is, date/times without an associated time zone), leaving it up to each developer to interpret what a given date/time "really means". This can cause all sorts of subtle timezone-related bugs.

In Django 1.4, you can now switch Django into a more correct, time-zone aware mode. In this mode, Django stores date and time information in UTC in the database, uses time-zone-aware datetime objects internally and translates them to the end user's time zone in templates and forms. Reasons for using this feature include:

- Customizing date and time display for users around the world.

- Storing datetimes in UTC for database portability and interoperability. (This argument doesn't apply to PostgreSQL, because it already stores timestamps with time zone information in Django 1.3.)
- Avoiding data corruption problems around DST transitions.

Time zone support is enabled by default in new projects created with `startproject`. If you want to use this feature in an existing project, read the [migration guide](#). If you encounter problems, there's a helpful [FAQ](#).

## Support for in-browser testing frameworks

Django 1.4 supports integration with in-browser testing frameworks like [Selenium](#). The new `django.test.LiveServerTestCase` base class lets you test the interactions between your site's front and back ends more comprehensively. See the [documentation](#) for more details and concrete examples.

## Updated default project layout and `manage.py`

Django 1.4 ships with an updated default project layout and `manage.py` file for the `startproject` management command. These fix some issues with the previous `manage.py` handling of Python import paths that caused double imports, trouble moving from development to deployment, and other difficult-to-debug path issues.

The previous `manage.py` called functions that are now deprecated, and thus projects upgrading to Django 1.4 should update their `manage.py`. (The old-style `manage.py` will continue to work as before until Django 1.6. In 1.5 it will raise `DeprecationWarning`).

The new recommended `manage.py` file should look like this:

```
#!/usr/bin/env python
import os, sys

if __name__ == "__main__":
    os.environ.setdefault("DJANGO_SETTINGS_MODULE", "{{ project_name }}.settings")

    from django.core.management import execute_from_command_line

    execute_from_command_line(sys.argv)
```

`{{ project_name }}` should be replaced with the Python package name of the actual project.

If settings, URLconfs and apps within the project are imported or referenced using the project name prefix (e.g. `myproject.settings`, `ROOT_URLCONF = "myproject.urls"`, etc.), the new `manage.py` will need to be moved one directory up, so it is outside the project package rather than adjacent to `settings.py` and `urls.py`.

For instance, with the following layout:

```
manage.py
mysite/
  __init__.py
  settings.py
  urls.py
  myapp/
    __init__.py
    models.py
```

You could import `mysite.settings`, `mysite.urls`, and `mysite.myapp`, but not `settings`, `urls`, or `myapp` as top-level modules.

Anything imported as a top-level module can be placed adjacent to the new `manage.py`. For instance, to decouple “myapp” from the project module and import it as just `myapp`, place it outside the `mysite/` directory:

```
manage.py
myapp/
    __init__.py
    models.py
mysite/
    __init__.py
    settings.py
    urls.py
```

If the same code is imported inconsistently (some places with the project prefix, some places without it), the imports will need to be cleaned up when switching to the new `manage.py`.

## Custom project and app templates

The `startapp` and `startproject` management commands now have a `--template` option for specifying a path or URL to a custom app or project template.

For example, Django will use the `/path/to/my_project_template` directory when you run the following command:

```
django-admin.py startproject --template=/path/to/my_project_template myproject
```

You can also now provide a destination directory as the second argument to both `startapp` and `startproject`:

```
django-admin.py startapp myapp /path/to/new/app
django-admin.py startproject myproject /path/to/new/project
```

For more information, see the `startapp` and `startproject` documentation.

## Improved WSGI support

The `startproject` management command now adds a `wsgi.py` module to the initial project layout, containing a simple WSGI application that can be used for *deploying with WSGI app servers*.

The *built-in development server* now supports using an externally-defined WSGI callable, which makes it possible to run `runserver` with the same WSGI configuration that is used for deployment. The new `WSGI_APPLICATION` setting lets you configure which WSGI callable `runserver` uses.

(The `runfcgi` management command also internally wraps the WSGI callable configured via `WSGI_APPLICATION`.)

## SELECT FOR UPDATE support

Django 1.4 includes a `QuerySet.select_for_update()` method, which generates a `SELECT ... FOR UPDATE` SQL query. This will lock rows until the end of the transaction, meaning other transactions cannot modify or delete rows matched by a `FOR UPDATE` query.

For more details, see the documentation for `select_for_update()`.

### `Model.objects.bulk_create` in the ORM

This method lets you create multiple objects more efficiently. It can result in significant performance increases if you have many objects.

Django makes use of this internally, meaning some operations (such as database setup for test suites) have seen a performance benefit as a result.

See the `bulk_create()` docs for more information.

### `QuerySet.prefetch_related`

Similar to `select_related()` but with a different strategy and broader scope, `prefetch_related()` has been added to `QuerySet`. This method returns a new `QuerySet` that will prefetch each of the specified related lookups in a single batch as soon as the query begins to be evaluated. Unlike `select_related`, it does the joins in Python, not in the database, and supports many-to-many relationships, `GenericForeignKey` and more. This allows you to fix a very common performance problem in which your code ends up doing  $O(n)$  database queries (or worse) if objects on your primary `QuerySet` each have many related objects that you also need to fetch.

### Improved password hashing

Django’s auth system (`django.contrib.auth`) stores passwords using a one-way algorithm. Django 1.3 uses the SHA1 algorithm, but increasing processor speeds and theoretical attacks have revealed that SHA1 isn’t as secure as we’d like. Thus, Django 1.4 introduces a new password storage system: by default Django now uses the PBKDF2 algorithm (as recommended by NIST). You can also easily choose a different algorithm (including the popular `bcrypt` algorithm). For more details, see *How Django stores passwords*.

### HTML5 doctype

We’ve switched the admin and other bundled templates to use the HTML5 doctype. While Django will be careful to maintain compatibility with older browsers, this change means that you can use any HTML5 features you need in admin pages without having to lose HTML validity or override the provided templates to change the doctype.

### List filters in admin interface

Prior to Django 1.4, the `admin` app let you specify change list filters by specifying a field lookup, but it didn’t allow you to create custom filters. This has been rectified with a simple API (previously used internally and known as “FilterSpec”). For more details, see the documentation for `list_filter`.

### Multiple sort in admin interface

The admin change list now supports sorting on multiple columns. It respects all elements of the `ordering` attribute, and sorting on multiple columns by clicking on headers is designed to mimic the behavior of desktop GUIs. We also added a `get_ordering()` method for specifying the ordering dynamically (i.e., depending on the request).

### New `ModelAdmin` methods

We added a `save_related()` method to `ModelAdmin` to ease customization of how related objects are saved in the admin.

Two other new `ModelAdmin` methods, `get_list_display()` and `get_list_display_links()` enable dynamic customization of fields and links displayed on the admin change list.

### Admin inlines respect user permissions

Admin inlines now only allow those actions for which the user has permission. For `ManyToMany` relationships with an auto-created intermediate model (which does not have its own permissions), the change permission for the related model determines if the user has the permission to add, change or delete relationships.

### Tools for cryptographic signing

Django 1.4 adds both a low-level API for signing values and a high-level API for setting and reading signed cookies, one of the most common uses of signing in Web applications.

See the [cryptographic signing](#) docs for more information.

### Cookie-based session backend

Django 1.4 introduces a cookie-based session backend that uses the tools for [cryptographic signing](#) to store the session data in the client's browser.

**Warning:** Session data is signed and validated by the server, but it's not encrypted. This means a user can view any data stored in the session but cannot change it. Please read the documentation for further clarification before using this backend.

See the [cookie-based session backend](#) docs for more information.

### New form wizard

The previous `FormWizard` from `django.contrib.formtools` has been replaced with a new implementation based on the class-based views introduced in Django 1.3. It features a pluggable storage API and doesn't require the wizard to pass around hidden fields for every previous step.

Django 1.4 ships with a session-based storage backend and a cookie-based storage backend. The latter uses the tools for [cryptographic signing](#) also introduced in Django 1.4 to store the wizard's state in the user's cookies.

### `reverse_lazy`

A lazily evaluated version of `reverse()` was added to allow using URL reversals before the project's `URLconf` gets loaded.

### Translating URL patterns

Django can now look for a language prefix in the `URLpattern` when using the new `i18n_patterns()` helper function. It's also now possible to define translatable URL patterns using `ugettext_lazy()`. See [Internationalization: in URL patterns](#) for more information about the language prefix and how to internationalize URL patterns.

## Contextual translation support for `{% trans %}` and `{% blocktrans %}`

The *contextual translation* support introduced in Django 1.3 via the `pgettext` function has been extended to the `trans` and `blocktrans` template tags using the new `context` keyword.

## Customizable `SingleObjectMixin` `URLConf` kwargs

Two new attributes, `pk_url_kwarg` and `slug_url_kwarg`, have been added to `SingleObjectMixin` to enable the customization of `URLConf` keyword arguments used for single object generic views.

## Assignment template tags

A new `assignment_tag` helper function was added to `template.Library` to ease the creation of template tags that store data in a specified context variable.

## `*args` and `**kwargs` support for template tag helper functions

The `simple_tag`, `inclusion_tag` and newly introduced `assignment_tag` template helper functions may now accept any number of positional or keyword arguments. For example:

```
@register.simple_tag
def my_tag(a, b, *args, **kwargs):
    warning = kwargs['warning']
    profile = kwargs['profile']
    ...
    return ...
```

Then, in the template, any number of arguments may be passed to the template tag. For example:

```
{% my_tag 123 "abcd" book.title warning=message|lower profile=user.profile %}
```

## No wrapping of exceptions in `TEMPLATE_DEBUG` mode

In previous versions of Django, whenever the `TEMPLATE_DEBUG` setting was `True`, any exception raised during template rendering (even exceptions unrelated to template syntax) were wrapped in `TemplateSyntaxError` and re-raised. This was done in order to provide detailed template source location information in the debug 500 page.

In Django 1.4, exceptions are no longer wrapped. Instead, the original exception is annotated with the source information. This means that catching exceptions from template rendering is now consistent regardless of the value of `TEMPLATE_DEBUG`, and there's no need to catch and unwrap `TemplateSyntaxError` in order to catch other errors.

## `truncatechars` template filter

This new filter truncates a string to be no longer than the specified number of characters. Truncated strings end with a translatable ellipsis sequence ("..."). See the documentation for `truncatechars` for more details.

## static template tag

The `staticfiles` contrib app has a new `static` template tag to refer to files saved with the `STATICFILES_STORAGE` storage backend. It uses the storage backend's `url` method and therefore supports advanced features such as *servng files from a cloud service*.

## CachedStaticFilesStorage storage backend

The `staticfiles` contrib app now has a `CachedStaticFilesStorage` backend that caches the files it saves (when running the `collectstatic` management command) by appending the MD5 hash of the file's content to the filename. For example, the file `css/styles.css` would also be saved as `css/styles.55e7cbb9ba48.css`

See the `CachedStaticFilesStorage` docs for more information.

## Simple clickjacking protection

We've added a middleware to provide easy protection against [clickjacking](#) using the `X-Frame-Options` header. It's not enabled by default for backwards compatibility reasons, but you'll almost certainly want to *enable it* to help plug that security hole for browsers that support the header.

## CSRF improvements

We've made various improvements to our CSRF features, including the `ensure_csrf_cookie()` decorator, which can help with AJAX-heavy sites; protection for PUT and DELETE requests; and the `CSRF_COOKIE_SECURE` and `CSRF_COOKIE_PATH` settings, which can improve the security and usefulness of CSRF protection. See the `CSRF docs` for more information.

## Error report filtering

We added two function decorators, `sensitive_variables()` and `sensitive_post_parameters()`, to allow designating the local variables and POST parameters that may contain sensitive information and should be filtered out of error reports.

All POST parameters are now systematically filtered out of error reports for certain views (`login`, `password_reset_confirm`, `password_change` and `add_view` in `django.contrib.auth.views`, as well as `user_change_password` in the admin app) to prevent the leaking of sensitive information such as user passwords.

You can override or customize the default filtering by writing a *custom filter*. For more information see the docs on *Filtering error reports*.

## Extended IPv6 support

Django 1.4 can now better handle IPv6 addresses with the new `GenericIPAddressField` model field, `GenericIPAddressField` form field and the validators `validate_ipv46_address` and `validate_ipv6_address`.

## HTML comparisons in tests

The base classes in `django.test` now have some helpers to compare HTML without tripping over irrelevant differences in whitespace, argument quoting/ordering and closing of self-closing tags. You can either compare HTML directly with the new `assertHTMLEqual()` and `assertHTMLNotEqual()` assertions, or use the `html=True` flag with `assertContains()` and `assertNotContains()` to test whether the client's response contains a given HTML fragment. See the [assertions documentation](#) for more.

## Two new date format strings

Two new `date` formats were added for use in template filters, template tags and *Format localization*:

- `e` – the name of the timezone of the given datetime object
- `o` – the ISO 8601 year number

Please make sure to update your *custom format files* if they contain either `e` or `o` in a format string. For example a Spanish localization format previously only escaped the `d` format character:

```
DATE_FORMAT = r'j \de F \de Y'
```

But now it needs to also escape `e` and `o`:

```
DATE_FORMAT = r'j \d\e F \d\e Y'
```

For more information, see the [date](#) documentation.

## Minor features

Django 1.4 also includes several smaller improvements worth noting:

- A more usable stacktrace in the technical 500 page. Frames in the stack trace that reference Django's framework code are dimmed out, while frames in application code are slightly emphasized. This change makes it easier to scan a stacktrace for issues in application code.
- *Tablespace support* in PostgreSQL.
- Customizable names for `simple_tag()`.
- In the documentation, a helpful *security overview* page.
- The `django.contrib.auth.models.check_password` function has been moved to the `django.contrib.auth.hashers` module. Importing it from the old location will still work, but you should update your imports.
- The `collectstatic` management command now has a `--clear` option to delete all files at the destination before copying or linking the static files.
- It's now possible to load fixtures containing forward references when using MySQL with the InnoDB database engine.
- A new 403 response handler has been added as `'django.views.defaults.permission_denied'`. You can set your own handler by setting the value of `django.conf.urls.handler403`. See the documentation about *the 403 (HTTP Forbidden) view* for more information.
- The `makemessages` command uses a new and more accurate lexer, `JsLex`, for extracting translatable strings from JavaScript files.

- The `trans` template tag now takes an optional `as` argument to be able to retrieve a translation string without displaying it but setting a template context variable instead.
- The `if` template tag now supports `{% elif %}` clauses.
- If your Django app is behind a proxy, you might find the new `SECURE_PROXY_SSL_HEADER` setting useful. It solves the problem of your proxy “eating” the fact that a request came in via HTTPS. But only use this setting if you know what you’re doing.
- A new, plain-text, version of the HTTP 500 status code internal error page served when `DEBUG` is `True` is now sent to the client when Django detects that the request has originated in JavaScript code. (`is_ajax()` is used for this.)

Like its HTML counterpart, it contains a collection of different pieces of information about the state of the application.

This should make it easier to read when debugging interaction with client-side JavaScript.

- Added the `makemessages --no-location` option.
- Changed the `locmem` cache backend to use `pickle.HIGHEST_PROTOCOL` for better compatibility with the other cache backends.
- Added support in the ORM for generating `SELECT` queries containing `DISTINCT ON`.

The `distinct()` `QuerySet` method now accepts an optional list of model field names. If specified, then the `DISTINCT` statement is limited to these fields. This is only supported in PostgreSQL.

For more details, see the documentation for `distinct()`.

- The admin login page will add a password reset link if you include a URL with the name `admin_password_reset` in your `urls.py`, so plugging in the built-in password reset mechanism and making it available is now much easier. For details, see [Adding a password-reset feature](#).
- The MySQL database backend can now make use of the savepoint feature implemented by MySQL version 5.0.3 or newer with the InnoDB storage engine.
- It’s now possible to pass initial values to the model forms that are part of both model formsets and inline model formsets as returned from factory functions `modelformset_factory` and `inlineformset_factory` respectively just like with regular formsets. However, initial values only apply to extra forms, i.e. those which are not bound to an existing model instance.
- The sitemaps framework can now handle HTTPS links using the new `Sitemap.protocol` class attribute.
- A new `django.test.SimpleTestCase` subclass of `unittest.TestCase` that’s lighter than `django.test.TestCase` and company. It can be useful in tests that don’t need to hit a database. See [Hierarchy of Django unit testing classes](#).

## Backwards incompatible changes in 1.4

### SECRET\_KEY setting is required

Running Django with an empty or known `SECRET_KEY` disables many of Django’s security protections and can lead to remote-code-execution vulnerabilities. No Django site should ever be run without a `SECRET_KEY`.

In Django 1.4, starting Django with an empty `SECRET_KEY` will raise a `DeprecationWarning`. In Django 1.5, it will raise an exception and Django will refuse to start. This is slightly accelerated from the usual deprecation path due to the severity of the consequences of running Django with no `SECRET_KEY`.

## `django.contrib.admin`

The included administration app `django.contrib.admin` has for a long time shipped with a default set of static files such as JavaScript, images and stylesheets. Django 1.3 added a new contrib app `django.contrib.staticfiles` to handle such files in a generic way and defined conventions for static files included in apps.

Starting in Django 1.4, the admin’s static files also follow this convention, to make the files easier to deploy. In previous versions of Django, it was also common to define an `ADMIN_MEDIA_PREFIX` setting to point to the URL where the admin’s static files live on a Web server. This setting has now been deprecated and replaced by the more general setting `STATIC_URL`. Django will now expect to find the admin static files under the URL `<STATIC_URL>/admin/`.

If you’ve previously used a URL path for `ADMIN_MEDIA_PREFIX` (e.g. `/media/`) simply make sure `STATIC_URL` and `STATIC_ROOT` are configured and your Web server serves those files correctly. The development server continues to serve the admin files just like before. Read the [static files howto](#) for more details.

If your `ADMIN_MEDIA_PREFIX` is set to an specific domain (e.g. `http://media.example.com/admin/`), make sure to also set your `STATIC_URL` setting to the correct URL – for example, `http://media.example.com/`.

**Warning:** If you’re implicitly relying on the path of the admin static files within Django’s source code, you’ll need to update that path. The files were moved from `django/contrib/admin/media/` to `django/contrib/admin/static/admin/`.

## Supported browsers for the admin

Django hasn’t had a clear policy on which browsers are supported by the admin app. Our new policy formalizes existing practices: [YUI’s A-grade](#) browsers should provide a fully-functional admin experience, with the notable exception of Internet Explorer 6, which is no longer supported.

Released over 10 years ago, IE6 imposes many limitations on modern Web development. The practical implications of this policy are that contributors are free to improve the admin without consideration for these limitations.

Obviously, this new policy **has no impact** on sites you develop using Django. It only applies to the Django admin. Feel free to develop apps compatible with any range of browsers.

## Removed admin icons

As part of an effort to improve the performance and usability of the admin’s change-list sorting interface and [horizontal](#) and [vertical](#) “filter” widgets, some icon files were removed and grouped into two sprite files.

Specifically: `selector-add.gif`, `selector-addall.gif`, `selector-remove.gif`, `selector-removeall.gif`, `selector_stacked-add.gif` and `selector_stacked-remove.gif` were combined into `selector-icons.gif`; and `arrow-up.gif` and `arrow-down.gif` were combined into `sorting-icons.gif`.

If you used those icons to customize the admin, then you’ll need to replace them with your own icons or get the files from a previous release.

## CSS class names in admin forms

To avoid conflicts with other common CSS class names (e.g. “button”), we added a prefix (“field-”) to all CSS class names automatically generated from the form field names in the main admin forms, stacked inline forms and tabular

inline cells. You'll need to take that prefix into account in your custom style sheets or JavaScript files if you previously used plain field names as selectors for custom styles or JavaScript transformations.

## Compatibility with old signed data

Django 1.3 changed the cryptographic signing mechanisms used in a number of places in Django. While Django 1.3 kept fallbacks that would accept hashes produced by the previous methods, these fallbacks are removed in Django 1.4.

So, if you upgrade to Django 1.4 directly from 1.2 or earlier, you may lose/invalidate certain pieces of data that have been cryptographically signed using an old method. To avoid this, use Django 1.3 first for a period of time to allow the signed data to expire naturally. The affected parts are detailed below, with 1) the consequences of ignoring this advice and 2) the amount of time you need to run Django 1.3 for the data to expire or become irrelevant.

- `contrib.sessions` data integrity check
  - Consequences: The user will be logged out, and session data will be lost.
  - Time period: Defined by `SESSION_COOKIE_AGE`.
- `contrib.auth` password reset hash
  - Consequences: Password reset links from before the upgrade will not work.
  - Time period: Defined by `PASSWORD_RESET_TIMEOUT_DAYS`.

Form-related hashes: these have a are much shorter lifetime and are relevant only for the short window where a user might fill in a form generated by the pre-upgrade Django instance and try to submit it to the upgraded Django instance:

- `contrib.comments` form security hash
  - Consequences: The user will see the validation error “Security hash failed.”
  - Time period: The amount of time you expect users to take filling out comment forms.
- `FormWizard` security hash
  - Consequences: The user will see an error about the form having expired and will be sent back to the first page of the wizard, losing the data entered so far.
  - Time period: The amount of time you expect users to take filling out the affected forms.
- CSRF check
  - Note: This is actually a Django 1.1 fallback, not Django 1.2, and it applies only if you're upgrading from 1.1.
  - Consequences: The user will see a 403 error with any CSRF-protected POST form.
  - Time period: The amount of time you expect user to take filling out such forms.
- `contrib.auth` user password hash-upgrade sequence
  - Consequences: Each user's password will be updated to a stronger password hash when it's written to the database in 1.4. This means that if you upgrade to 1.4 and then need to downgrade to 1.3, version 1.3 won't be able to read the updated passwords.
  - Remedy: Set `PASSWORD_HASHERS` to use your original password hashing when you initially upgrade to 1.4. After you confirm your app works well with Django 1.4 and you won't have to roll back to 1.3, enable the new password hashes.

### `django.contrib.flatpages`

Starting in 1.4, the `FlatpageFallbackMiddleware` only adds a trailing slash and redirects if the resulting URL refers to an existing flatpage. For example, requesting `/notafatpageoravalidurl` in a previous version would redirect to `/notafatpageoravalidurl/`, which would subsequently raise a 404. Requesting `/notafatpageoravalidurl` now will immediately raise a 404.

Also, redirects returned by flatpages are now permanent (with 301 status code), to match the behavior of `CommonMiddleware`.

### Serialization of `datetime` and `time`

As a consequence of time-zone support, and according to the ECMA-262 specification, we made changes to the JSON serializer:

- It includes the time zone for aware datetime objects. It raises an exception for aware time objects.
- It includes milliseconds for datetime and time objects. There is still some precision loss, because Python stores microseconds (6 digits) and JSON only supports milliseconds (3 digits). However, it's better than discarding microseconds entirely.

We changed the XML serializer to use the ISO8601 format for datetimes. The letter T is used to separate the date part from the time part, instead of a space. Time zone information is included in the `[+-]HH:MM` format.

Though the serializers now use these new formats when creating fixtures, they can still load fixtures that use the old format.

### `supports_timezone` changed to `False` for SQLite

The database feature `supports_timezone` used to be `True` for SQLite. Indeed, if you saved an aware datetime object, SQLite stored a string that included an UTC offset. However, this offset was ignored when loading the value back from the database, which could corrupt the data.

In the context of time-zone support, this flag was changed to `False`, and datetimes are now stored without time-zone information in SQLite. When `USE_TZ` is `False`, if you attempt to save an aware datetime object, Django raises an exception.

### MySQLdb-specific exceptions

The MySQL backend historically has raised `MySQLdb.OperationalError` when a query triggered an exception. We've fixed this bug, and we now raise `django.db.DatabaseError` instead. If you were testing for `MySQLdb.OperationalError`, you'll need to update your `except` clauses.

### Database connection's thread-locality

`DatabaseWrapper` objects (i.e. the connection objects referenced by `django.db.connection` and `django.db.connections["some_alias"]`) used to be thread-local. They are now global objects in order to be potentially shared between multiple threads. While the individual connection objects are now global, the `django.db.connections` dictionary referencing those objects is still thread-local. Therefore if you just use the ORM or `DatabaseWrapper.cursor()` then the behavior is still the same as before. Note, however, that `django.db.connection` does not directly reference the default `DatabaseWrapper` object anymore and is now a proxy to access that object's attributes. If you need to access the actual `DatabaseWrapper` object, use `django.db.connections[DEFAULT_DB_ALIAS]` instead.

As part of this change, all underlying SQLite connections are now enabled for potential thread-sharing (by passing the `check_same_thread=False` attribute to `pysqlite`). `DatabaseWrapper` however preserves the previous behavior by disabling thread-sharing by default, so this does not affect any existing code that purely relies on the ORM or on `DatabaseWrapper.cursor()`.

Finally, while it's now possible to pass connections between threads, Django doesn't make any effort to synchronize access to the underlying backend. Concurrency behavior is defined by the underlying backend implementation. Check their documentation for details.

### **`COMMENTS_BANNED_USERS_GROUP` setting**

Django's comments has historically supported excluding the comments of a special user group, but we've never documented the feature properly and didn't enforce the exclusion in other parts of the app such as the template tags. To fix this problem, we removed the code from the feed class.

If you rely on the feature and want to restore the old behavior, use a custom comment model manager to exclude the user group, like this:

```
from django.conf import settings
from django.contrib.comments.managers import CommentManager

class BanningCommentManager(CommentManager):
    def get_query_set(self):
        qs = super(BanningCommentManager, self).get_query_set()
        if getattr(settings, 'COMMENTS_BANNED_USERS_GROUP', None):
            where = ['user_id NOT IN (SELECT user_id FROM auth_user_groups WHERE_
↳group_id = %s)']
            params = [settings.COMMENTS_BANNED_USERS_GROUP]
            qs = qs.extra(where=where, params=params)
        return qs
```

Save this model manager in your custom comment app (e.g., in `my_comments_app/managers.py`) and add it your custom comment app model:

```
from django.db import models
from django.contrib.comments.models import Comment

from my_comments_app.managers import BanningCommentManager

class CommentWithTitle(Comment):
    title = models.CharField(max_length=300)

    objects = BanningCommentManager()
```

### **`IGNORABLE_404_STARTS` and `IGNORABLE_404_ENDS` settings**

Until Django 1.3, it was possible to exclude some URLs from Django's *404 error reporting* by adding prefixes to `IGNORABLE_404_STARTS` and suffixes to `IGNORABLE_404_ENDS`.

In Django 1.4, these two settings are superseded by `IGNORABLE_404_URLS`, which is a list of compiled regular expressions. Django won't send an email for 404 errors on URLs that match any of them.

Furthermore, the previous settings had some rather arbitrary default values:

```
IGNORABLE_404_STARTS = ('/cgi-bin/', '/_vti_bin', '/_vti_inf')
IGNORABLE_404_ENDS = ('mail.pl', 'mailform.pl', 'mail.cgi', 'mailform.cgi',
                      'favicon.ico', '.php')
```

It's not Django's role to decide if your website has a legacy `/cgi-bin/` section or a `favicon.ico`. As a consequence, the default values of `IGNORABLE_404_URLS`, `IGNORABLE_404_STARTS`, and `IGNORABLE_404_ENDS` are all now empty.

If you have customized `IGNORABLE_404_STARTS` or `IGNORABLE_404_ENDS`, or if you want to keep the old default value, you should add the following lines in your settings file:

```
import re
IGNORABLE_404_URLS = (
    # for each <prefix> in IGNORABLE_404_STARTS
    re.compile(r'^<prefix>'),
    # for each <suffix> in IGNORABLE_404_ENDS
    re.compile(r'<suffix>$'),
)
```

Don't forget to escape characters that have a special meaning in a regular expression, such as periods.

### CSRF protection extended to PUT and DELETE

Previously, Django's *CSRF protection* provided protection only against POST requests. Since use of PUT and DELETE methods in AJAX applications is becoming more common, we now protect all methods not defined as safe by [RFC 2616](#) – i.e., we exempt GET, HEAD, OPTIONS and TRACE, and we enforce protection on everything else.

If you're using PUT or DELETE methods in AJAX applications, please see the *instructions about using AJAX and CSRF*.

### Password reset view now accepts `subject_template_name`

The `password_reset` view in `django.contrib.auth` now accepts a `subject_template_name` parameter, which is passed to the password save form as a keyword argument. If you are using this view with a custom password reset form, then you will need to ensure your form's `save()` method accepts this keyword argument.

### `django.core.template_loaders`

This was an alias to `django.template.loader` since 2005, and we've removed it without emitting a warning due to the length of the deprecation. If your code still referenced this, please use `django.template.loader` instead.

### `django.db.models.fields.URLField.verify_exists`

This functionality has been removed due to intractable performance and security issues. Any existing usage of `verify_exists` should be removed.

### `django.core.files.storage.Storage.open`

The `open` method of the base `Storage` class used to take an obscure parameter `mixin` that allowed you to dynamically change the base classes of the returned file object. This has been removed. In the rare case you relied on the `mixin` parameter, you can easily achieve the same by overriding the `open` method, like this:

```
from django.core.files import File
from django.core.files.storage import FileSystemStorage

class Spam(File):
    """
    Spam, spam, spam, spam and spam.
    """
    def ham(self):
        return 'eggs'

class SpamStorage(FileSystemStorage):
    """
    A custom file storage backend.
    """
    def open(self, name, mode='rb'):
        return Spam(open(self.path(name), mode))
```

### YAML deserializer now uses `yaml.safe_load`

`yaml.load` is able to construct any Python object, which may trigger arbitrary code execution if you process a YAML document that comes from an untrusted source. This feature isn't necessary for Django's YAML deserializer, whose primary use is to load fixtures consisting of simple objects. Even though fixtures are trusted data, the YAML deserializer now uses `yaml.safe_load` for additional security.

### Session cookies now have the `httponly` flag by default

Session cookies now include the `httponly` attribute by default to help reduce the impact of potential XSS attacks. As a consequence of this change, session cookie data, including `sessionid`, is no longer accessible from JavaScript in many browsers. For strict backwards compatibility, use `SESSION_COOKIE_HTTPONLY = False` in your settings file.

### The `urlize` filter no longer escapes every URL

When a URL contains a `%xx` sequence, where `xx` are two hexadecimal digits, `urlize` now assumes that the URL is already escaped and doesn't apply URL escaping again. This is wrong for URLs whose unquoted form contains a `%xx` sequence, but such URLs are very unlikely to happen in the wild, because they would confuse browsers too.

### `assertTemplateUsed` and `assertTemplateNotUsed` as context manager

It's now possible to check whether a template was used within a block of code with `assertTemplateUsed()` and `assertTemplateNotUsed()`. And they can be used as a context manager:

```
with self.assertTemplateUsed('index.html'):
    render_to_string('index.html')
```

```
with self.assertTemplateNotUsed('base.html'):  
    render_to_string('index.html')
```

See the [assertion documentation](#) for more.

## Database connections after running the test suite

The default test runner no longer restores the database connections after tests' execution. This prevents the production database from being exposed to potential threads that would still be running and attempting to create new connections.

If your code relied on connections to the production database being created after tests' execution, then you can restore the previous behavior by subclassing `DjangoTestRunner` and overriding its `teardown_databases()` method.

## Output of `manage.py help`

`manage.py help` now groups available commands by application. If you depended on the output of this command – if you parsed it, for example – then you'll need to update your code. To get a list of all available management commands in a script, use `manage.py help --commands` instead.

## extends template tag

Previously, the `extends` tag used a buggy method of parsing arguments, which could lead to it erroneously considering an argument as a string literal when it wasn't. It now uses `parser.compile_filter`, like other tags.

The internals of the tag aren't part of the official stable API, but in the interests of full disclosure, the `ExtendsNode.__init__` definition has changed, which may break any custom tags that use this class.

## Loading some incomplete fixtures no longer works

Prior to 1.4, a default value was inserted for fixture objects that were missing a specific date or datetime value when `auto_now` or `auto_now_add` was set for the field. This was something that should not have worked, and in 1.4 loading such incomplete fixtures will fail. Because fixtures are a raw import, they should explicitly specify all field values, regardless of field options on the model.

## Development Server Multithreading

The development server is now multithreaded by default. Use the `runserver --nothreading` option to disable the use of threading in the development server:

```
django-admin.py runserver --nothreading
```

## Attributes disabled in markdown when safe mode set

Prior to Django 1.4, attributes were included in any markdown output regardless of safe mode setting of the filter. With version > 2.1 of the Python-Markdown library, an `enable_attributes` option was added. When the `safe` argument is passed to the markdown filter, both the `safe_mode=True` and `enable_attributes=False` options are set. If using a version of the Python-Markdown library less than 2.1, a warning is issued that the output is insecure.

## FormMixin `get_initial` returns an instance-specific dictionary

In Django 1.3, the `get_initial` method of the `django.views.generic.edit.FormMixin` class was returning the class `initial` dictionary. This has been fixed to return a copy of this dictionary, so form instances can modify their initial data without messing with the class variable.

## Features deprecated in 1.4

### Old styles of calling `cache_page` decorator

Some legacy ways of calling `cache_page()` have been deprecated. Please see the documentation for the correct way to use this decorator.

### Support for PostgreSQL versions older than 8.2

Django 1.3 dropped support for PostgreSQL versions older than 8.0, and we suggested using a more recent version because of performance improvements and, more importantly, the end of upstream support periods for 8.0 and 8.1 was near (November 2010).

Django 1.4 takes that policy further and sets 8.2 as the minimum PostgreSQL version it officially supports.

### Request exceptions are now always logged

When we added *logging support* in Django in 1.3, the admin error email support was moved into the `django.utils.log.AdminEmailHandler`, attached to the `'django.request'` logger. In order to maintain the established behavior of error emails, the `'django.request'` logger was called only when `DEBUG` was `False`.

To increase the flexibility of error logging for requests, the `'django.request'` logger is now called regardless of the value of `DEBUG`, and the default settings file for new projects now includes a separate filter attached to `django.utils.log.AdminEmailHandler` to prevent admin error emails in `DEBUG` mode:

```
'filters': {
    'require_debug_false': {
        '()': 'django.utils.log.RequireDebugFalse'
    }
},
'handlers': {
    'mail_admins': {
        'level': 'ERROR',
        'filters': ['require_debug_false'],
        'class': 'django.utils.log.AdminEmailHandler'
    }
},
```

If your project was created prior to this change, your `LOGGING` setting will not include this new filter. In order to maintain backwards-compatibility, Django will detect that your `'mail_admins'` handler configuration includes no `'filters'` section and will automatically add this filter for you and issue a pending-deprecation warning. This will become a deprecation warning in Django 1.5, and in Django 1.6 the backwards-compatibility shim will be removed entirely.

The existence of any `'filters'` key under the `'mail_admins'` handler will disable this backward-compatibility shim and deprecation warning.

### `django.conf.urls.defaults`

Until Django 1.3, the functions `include()`, `patterns()` and `url()` plus `handler404`, `handler500` were located in a `django.conf.urls.defaults` module.

In Django 1.4, they live in `django.conf.urls`.

### `django.contrib.databrowse`

Databrowse has not seen active development for some time, and this does not show any sign of changing. There had been a suggestion for a [GSOC project](#) to integrate the functionality of databrowse into the admin, but no progress was made. While Databrowse has been deprecated, an enhancement of `django.contrib.admin` providing a similar feature set is still possible.

The code that powers Databrowse is licensed under the same terms as Django itself, so it's available to be adopted by an individual or group as a third-party project.

### `django.core.management.setup_environ`

This function temporarily modified `sys.path` in order to make the parent “project” directory importable under the old flat `startproject` layout. This function is now deprecated, as its path workarounds are no longer needed with the new `manage.py` and default project layout.

This function was never documented or part of the public API, but it was widely recommended for use in setting up a “Django environment” for a user script. These uses should be replaced by setting the `DJANGO_SETTINGS_MODULE` environment variable or using `django.conf.settings.configure()`.

### `django.core.management.execute_manager`

This function was previously used by `manage.py` to execute a management command. It is identical to `django.core.management.execute_from_command_line`, except that it first calls `setup_environ`, which is now deprecated. As such, `execute_manager` is also deprecated; `execute_from_command_line` can be used instead. Neither of these functions is documented as part of the public API, but a deprecation path is needed due to use in existing `manage.py` files.

### `is_safe` and `needs_autoescape` attributes of template filters

Two flags, `is_safe` and `needs_autoescape`, define how each template filter interacts with Django's auto-escaping behavior. They used to be attributes of the filter function:

```
@register.filter
def noop(value):
    return value
noop.is_safe = True
```

However, this technique caused some problems in combination with decorators, especially `@stringfilter`. Now, the flags are keyword arguments of `@register.filter`:

```
@register.filter(is_safe=True)
def noop(value):
    return value
```

See *filters and auto-escaping* for more information.

## Wildcard expansion of application names in `INSTALLED_APPS`

Until Django 1.3, `INSTALLED_APPS` accepted wildcards in application names, like `django.contrib.*`. The expansion was performed by a filesystem-based implementation of `from <package> import *`. Unfortunately, this can't be done reliably.

This behavior was never documented. Since it is unpythonic and not obviously useful, it was removed in Django 1.4. If you relied on it, you must edit your settings file to list all your applications explicitly.

## `HttpRequest.raw_post_data` renamed to `HttpRequest.body`

This attribute was confusingly named `HttpRequest.raw_post_data`, but it actually provided the body of the HTTP request. It's been renamed to `HttpRequest.body`, and `HttpRequest.raw_post_data` has been deprecated.

## `django.contrib.sitemaps` bug fix with potential performance implications

In previous versions, `Paginator` objects used in sitemap classes were cached, which could result in stale site maps. We've removed the caching, so each request to a site map now creates a new `Paginator` object and calls the `items()` method of the `Sitemap` subclass. Depending on what your `items()` method is doing, this may have a negative performance impact. To mitigate the performance impact, consider using the *caching framework* within your `Sitemap` subclass.

## Versions of Python-Markdown earlier than 2.1

Versions of Python-Markdown earlier than 2.1 do not support the option to disable attributes. As a security issue, earlier versions of this library will not be supported by the markup contrib app in 1.5 under an accelerated deprecation timeline.

## 9.1.8 1.3 release

### Django 1.3.7 release notes

*February 20, 2013*

Django 1.3.7 corrects a packaging problem with yesterday's *1.3.6 release*.

The release contained stray `.pyc` files that caused "bad magic number" errors when running with some versions of Python. This release corrects this, and also fixes a bad documentation link in the project template `settings.py` file generated by `manage.py startproject`.

### Django 1.3.6 release notes

*February 19, 2013*

Django 1.3.6 fixes four security issues present in previous Django releases in the 1.3 series.

This is the sixth bugfix/security release in the Django 1.3 series.

## Host header poisoning

Some parts of Django – independent of end-user-written applications – make use of full URLs, including domain name, which are generated from the HTTP Host header. Django’s documentation has for some time contained notes advising users on how to configure Web servers to ensure that only valid Host headers can reach the Django application. However, it has been reported to us that even with the recommended Web server configurations there are still techniques available for tricking many common Web servers into supplying the application with an incorrect and possibly malicious Host header.

For this reason, Django 1.3.6 adds a new setting, `ALLOWED_HOSTS`, which should contain an explicit list of valid host/domain names for this site. A request with a Host header not matching an entry in this list will raise `SuspiciousOperation` if `request.get_host()` is called. For full details see the documentation for the `ALLOWED_HOSTS` setting.

The default value for this setting in Django 1.3.6 is `['*']` (matching any host), for backwards-compatibility, but we strongly encourage all sites to set a more restrictive value.

This host validation is disabled when `DEBUG` is `True` or when running tests.

## XML deserialization

The XML parser in the Python standard library is vulnerable to a number of attacks via external entities and entity expansion. Django uses this parser for deserializing XML-formatted database fixtures. The fixture deserializer is not intended for use with untrusted data, but in order to err on the side of safety in Django 1.3.6 the XML deserializer refuses to parse an XML document with a DTD (DOCTYPE definition), which closes off these attack avenues.

These issues in the Python standard library are CVE-2013-1664 and CVE-2013-1665. More information available [from the Python security team](#).

Django’s XML serializer does not create documents with a DTD, so this should not cause any issues with the typical round-trip from `dumpdata` to `loaddata`, but if you feed your own XML documents to the `loaddata` management command, you will need to ensure they do not contain a DTD.

## Formset memory exhaustion

Previous versions of Django did not validate or limit the form-count data provided by the client in a formset’s management form, making it possible to exhaust a server’s available memory by forcing it to create very large numbers of forms.

In Django 1.3.6, all formsets have a strictly-enforced maximum number of forms (1000 by default, though it can be set higher via the `max_num` formset factory argument).

## Admin history view information leakage

In previous versions of Django, an admin user without change permission on a model could still view the unicode representation of instances via their admin history log. Django 1.3.6 now limits the admin history log view for an object to users with change permission for that model.

## Django 1.3.5 release notes

*December 10, 2012*

Django 1.3.5 addresses two security issues present in previous Django releases in the 1.3 series.

Please be aware that this security release is slightly different from previous ones. Both issues addressed here have been dealt with in prior security updates to Django. In one case, we have received ongoing reports of problems, and in the other we've chosen to take further steps to tighten up Django's code in response to independent discovery of potential problems from multiple sources.

## Host header poisoning

Several earlier Django security releases focused on the issue of poisoning the HTTP Host header, causing Django to generate URLs pointing to arbitrary, potentially-malicious domains.

In response to further input received and reports of continuing issues following the previous release, we're taking additional steps to tighten Host header validation. Rather than attempt to accommodate all features HTTP supports here, Django's Host header validation attempts to support a smaller, but far more common, subset:

- Hostnames must consist of characters `[A-Za-z0-9]` plus hyphen ('-') or dot ('.').
- IP addresses – both IPv4 and IPv6 – are permitted.
- Port, if specified, is numeric.

Any deviation from this will now be rejected, raising the exception `django.core.exceptions.SuspiciousOperation`.

## Redirect poisoning

Also following up on a previous issue: in July of this year, we made changes to Django's HTTP redirect classes, performing additional validation of the scheme of the URL to redirect to (since, both within Django's own supplied applications and many third-party applications, accepting a user-supplied redirect target is a common pattern).

Since then, two independent audits of the code turned up further potential problems. So, similar to the Host-header issue, we are taking steps to provide tighter validation in response to reported problems (primarily with third-party applications, but to a certain extent also within Django itself). This comes in two parts:

1. A new utility function, `django.utils.http.is_safe_url`, is added; this function takes a URL and a hostname, and checks that the URL is either relative, or if absolute matches the supplied hostname. This function is intended for use whenever user-supplied redirect targets are accepted, to ensure that such redirects cannot lead to arbitrary third-party sites.
2. All of Django's own built-in views – primarily in the authentication system – which allow user-supplied redirect targets now use `is_safe_url` to validate the supplied URL.

## Django 1.3.4 release notes

*October 17, 2012*

This is the fourth release in the Django 1.3 series.

## Host header poisoning

Some parts of Django – independent of end-user-written applications – make use of full URLs, including domain name, which are generated from the HTTP Host header. Some attacks against this are beyond Django's ability to control, and require the web server to be properly configured; Django's documentation has for some time contained notes advising users on such configuration.

Django’s own built-in parsing of the Host header is, however, still vulnerable, as was reported to us recently. The Host header parsing in Django 1.3.3 and Django 1.4.1 – specifically, `django.http.HttpRequest.get_host()` – was incorrectly handling username/password information in the header. Thus, for example, the following Host header would be accepted by Django when running on “validsite.com”:

```
Host: validsite.com:random@evilsite.com
```

Using this, an attacker can cause parts of Django – particularly the password-reset mechanism – to generate and display arbitrary URLs to users.

To remedy this, the parsing in `HttpRequest.get_host()` is being modified; Host headers which contain potentially dangerous content (such as username/password pairs) now raise the exception `django.core.exceptions.SuspiciousOperation`.

Details of this issue were initially posted online as a [security advisory](#).

### Django 1.3.3 release notes

*August 1, 2012*

Following Monday’s security release of [Django 1.3.2](#), we began receiving reports that one of the fixes applied was breaking Python 2.4 compatibility for Django 1.3. Since Python 2.4 is a supported Python version for that release series, this release fixes compatibility with Python 2.4.

### Django 1.3.2 release notes

*July 30, 2012*

This is the second security release in the Django 1.3 series, fixing several security issues in Django 1.3. Django 1.3.2 is a recommended upgrade for all users of Django 1.3.

For a full list of issues addressed in this release, see the [security advisory](#).

### Django 1.3.1 release notes

*September 9, 2011*

Welcome to Django 1.3.1!

This is the first security release in the Django 1.3 series, fixing several security issues in Django 1.3. Django 1.3.1 is a recommended upgrade for all users of Django 1.3.

For a full list of issues addressed in this release, see the [security advisory](#).

### Django 1.3 release notes

*March 23, 2011*

Welcome to Django 1.3!

Nearly a year in the making, Django 1.3 includes quite a few [new features](#) and plenty of bug fixes and improvements to existing features. These release notes cover the new features in 1.3, as well as some [backwards-incompatible changes](#) you’ll want to be aware of when upgrading from Django 1.2 or older versions.

## Overview

Django 1.3's focus has mostly been on resolving smaller, long-standing feature requests, but that hasn't prevented a few fairly significant new features from landing, including:

- A framework for writing *class-based views*.
- Built-in support for *using Python's logging facilities*.
- Contrib support for *easy handling of static files*.
- Django's testing framework now supports (and ships with a copy of) *the unittest2 library*.

Wherever possible, of course, new features are introduced in a backwards-compatible manner per *our API stability policy* policy. As a result of this policy, Django 1.3 *begins the deprecation process for some features*.

## Python compatibility

The release of Django 1.2 was notable for having the first shift in Django's Python compatibility policy; prior to Django 1.2, Django supported any 2.x version of Python from 2.3 up. As of Django 1.2, the minimum requirement was raised to Python 2.4.

Django 1.3 continues to support Python 2.4, but will be the final Django release series to do so; beginning with Django 1.4, the minimum supported Python version will be 2.5. A document outlining our full timeline for deprecating Python 2.x and moving to Python 3.x will be published shortly after the release of Django 1.3.

## What's new in Django 1.3

### Class-based views

Django 1.3 adds a framework that allows you to use a class as a view. This means you can compose a view out of a collection of methods that can be subclassed and overridden to provide common views of data without having to write too much code.

Analogues of all the old function-based generic views have been provided, along with a completely generic view base class that can be used as the basis for reusable applications that can be easily extended.

See *the documentation on class-based generic views* for more details. There is also a document to help you *convert your function-based generic views to class-based views*.

### Logging

Django 1.3 adds framework-level support for Python's logging module. This means you can now easily configure and control logging as part of your Django project. A number of logging handlers and logging calls have been added to Django's own code as well – most notably, the error emails sent on a HTTP 500 server error are now handled as a logging activity. See *the documentation on Django's logging interface* for more details.

### Extended static files handling

Django 1.3 ships with a new contrib app – `django.contrib.staticfiles` – to help developers handle the static media files (images, CSS, JavaScript, etc.) that are needed to render a complete web page.

In previous versions of Django, it was common to place static assets in `MEDIA_ROOT` along with user-uploaded files, and serve them both at `MEDIA_URL`. Part of the purpose of introducing the `staticfiles` app is to make it easier

to keep static files separate from user-uploaded files. Static assets should now go in `static/` subdirectories of your apps or in other static assets directories listed in `STATICFILES_DIRS`, and will be served at `STATIC_URL`.

See the *reference documentation of the app* for more details or learn how to *manage static files*.

## unittest2 support

Python 2.7 introduced some major changes to the `unittest` library, adding some extremely useful features. To ensure that every Django project can benefit from these new features, Django ships with a copy of `unittest2`, a copy of the Python 2.7 `unittest` library, backported for Python 2.4 compatibility.

To access this library, Django provides the `django.utils.unittest` module alias. If you are using Python 2.7, or you have installed `unittest2` locally, Django will map the alias to the installed version of the `unittest` library. Otherwise, Django will use its own bundled version of `unittest2`.

To take advantage of this alias, simply use:

```
from django.utils import unittest
```

wherever you would have historically used:

```
import unittest
```

If you want to continue to use the base `unittest` library, you can – you just won't get any of the nice new `unittest2` features.

## Transaction context managers

Users of Python 2.5 and above may now use transaction management functions as context managers. For example:

```
with transaction.autocommit():  
    # ...
```

## Configurable delete-cascade

`ForeignKey` and `OneToOneField` now accept an `on_delete` argument to customize behavior when the referenced object is deleted. Previously, deletes were always cascaded; available alternatives now include `set null`, `set default`, `set to any value`, `protect`, or `do nothing`.

For more information, see the *on\_delete* documentation.

## Contextual markers and comments for translatable strings

For translation strings with ambiguous meaning, you can now use the `pgettext` function to specify the context of the string.

And if you just want to add some information for translators, you can also add special translator comments in the source.

For more information, see *Contextual markers* and *Comments for translators*.

## Improvements to built-in template tags

A number of improvements have been made to Django's built-in template tags:

- The `include` tag now accepts a `with` option, allowing you to specify context variables to the included template
- The `include` tag now accepts an `only` option, allowing you to exclude the current context from the included context
- The `with` tag now allows you to define multiple context variables in a single `with` block.
- The `load` tag now accepts a `from` argument, allowing you to load a single tag or filter from a library.

## TemplateResponse

It can sometimes be beneficial to allow decorators or middleware to modify a response *after* it has been constructed by the view. For example, you may want to change the template that is used, or put additional data into the context.

However, you can't (easily) modify the content of a basic `HttpResponse` after it has been constructed. To overcome this limitation, Django 1.3 adds a new `TemplateResponse` class. Unlike basic `HttpResponse` objects, `TemplateResponse` objects retain the details of the template and context that was provided by the view to compute the response. The final output of the response is not computed until it is needed, later in the response process.

For more details, see the [documentation](#) on the `TemplateResponse` class.

## Caching changes

Django 1.3 sees the introduction of several improvements to the Django's caching infrastructure.

Firstly, Django now supports multiple named caches. In the same way that Django 1.2 introduced support for multiple database connections, Django 1.3 allows you to use the new `CACHES` setting to define multiple named cache connections.

Secondly, *versioning*, *site-wide prefixing* and *transformation* have been added to the cache API.

Thirdly, *cache key creation* has been updated to take the request query string into account on GET requests.

Finally, support for `pylibmc` has been added to the memcached cache backend.

For more details, see the [documentation on caching in Django](#).

## Permissions for inactive users

If you provide a custom auth backend with `supports_inactive_user` set to `True`, an inactive `User` instance will check the backend for permissions. This is useful for further centralizing the permission handling. See the [authentication docs](#) for more details.

## GeoDjango

The GeoDjango test suite is now included when *running the Django test suite* with `runtests.py` when using *spatial database backends*.

## MEDIA\_URL and STATIC\_URL must end in a slash

Previously, the `MEDIA_URL` setting only required a trailing slash if it contained a suffix beyond the domain name.

A trailing slash is now *required* for `MEDIA_URL` and the new `STATIC_URL` setting as long as it is not blank. This ensures there is a consistent way to combine paths in templates.

Project settings which provide either of both settings without a trailing slash will now raise a `PendingDeprecationWarning`.

In Django 1.4 this same condition will raise `DeprecationWarning`, and in Django 1.5 will raise an `ImproperlyConfigured` exception.

## Everything else

Django *1.1* and *1.2* added lots of big ticket items to Django, like multiple-database support, model validation, and a session-based messages framework. However, this focus on big features came at the cost of lots of smaller features.

To compensate for this, the focus of the Django 1.3 development process has been on adding lots of smaller, long standing feature requests. These include:

- Improved tools for accessing and manipulating the current `Site` object in *the sites framework*.
- A `RequestFactory` for mocking requests in tests.
- A new test assertion – `assertNumQueries()` – making it easier to test the database activity associated with a view.
- Support for lookups spanning relations in admin’s `list_filter`.
- Support for `HTTPOnly` cookies.
- `mail_admins()` and `mail_managers()` now support easily attaching HTML content to messages.
- `EmailMessage` now supports CC’s.
- Error emails now include more of the detail and formatting of the debug server error page.
- `simple_tag()` now accepts a `takes_context` argument, making it easier to write simple template tags that require access to template context.
- A new `render()` shortcut – an alternative to `django.shortcuts.render_to_response()` providing a `RequestContext` by default.
- Support for combining *F expressions* with timedelta values when retrieving or updating database values.

## Backwards-incompatible changes in 1.3

### CSRF validation now applies to AJAX requests

Prior to Django 1.2.5, Django’s CSRF-prevention system exempted AJAX requests from CSRF verification; due to *security issues* reported to us, however, *all* requests are now subjected to CSRF verification. Consult *the Django CSRF documentation* for details on how to handle CSRF verification in AJAX requests.

## Restricted filters in admin interface

Prior to Django 1.2.5, the Django administrative interface allowed filtering on any model field or relation – not just those specified in `list_filter` – via query string manipulation. Due to security issues reported to us, however, query string lookup arguments in the admin must be for fields or relations specified in `list_filter` or `date_hierarchy`.

## Deleting a model doesn't delete associated files

In earlier Django versions, when a model instance containing a `FileField` was deleted, `FileField` took it upon itself to also delete the file from the backend storage. This opened the door to several data-loss scenarios, including rolled-back transactions and fields on different models referencing the same file. In Django 1.3, when a model is deleted the `FileField`'s `delete()` method won't be called. If you need cleanup of orphaned files, you'll need to handle it yourself (for instance, with a custom management command that can be run manually or scheduled to run periodically via e.g. cron).

## PasswordInput default rendering behavior

The `PasswordInput` form widget, intended for use with form fields which represent passwords, accepts a boolean keyword argument `render_value` indicating whether to send its data back to the browser when displaying a submitted form with errors. Prior to Django 1.3, this argument defaulted to `True`, meaning that the submitted password would be sent back to the browser as part of the form. Developers who wished to add a bit of additional security by excluding that value from the redisplayed form could instantiate a `PasswordInput` passing `render_value=False`.

Due to the sensitive nature of passwords, however, Django 1.3 takes this step automatically; the default value of `render_value` is now `False`, and developers who want the password value returned to the browser on a submission with errors (the previous behavior) must now explicitly indicate this. For example:

```
class LoginForm(forms.Form):
    username = forms.CharField(max_length=100)
    password = forms.CharField(widget=forms.PasswordInput(render_value=True))
```

## Clearable default widget for FileField

Django 1.3 now includes a `ClearableFileInput` form widget in addition to `FileInput`. `ClearableFileInput` renders with a checkbox to clear the field's value (if the field has a value and is not required); `FileInput` provided no means for clearing an existing file from a `FileField`.

`ClearableFileInput` is now the default widget for a `FileField`, so existing forms including `FileField` without assigning a custom widget will need to account for the possible extra checkbox in the rendered form output.

To return to the previous rendering (without the ability to clear the `FileField`), use the `FileInput` widget in place of `ClearableFileInput`. For instance, in a `ModelForm` for a hypothetical `Document` model with a `FileField` named `document`:

```
from django import forms
from myapp.models import Document

class DocumentForm(forms.ModelForm):
    class Meta:
        model = Document
        widgets = {'document': forms.FileInput}
```

## New index on database session table

Prior to Django 1.3, the database table used by the database backend for the `sessions` app had no index on the `expire_date` column. As a result, date-based queries on the session table – such as the query that is needed to purge old sessions – would be very slow if there were lots of sessions.

If you have an existing project that is using the database session backend, you don't have to do anything to accommodate this change. However, you may get a significant performance boost if you manually add the new index to the session table. The SQL that will add the index can be found by running the `sqlindexes` admin command:

```
python manage.py sqlindexes sessions
```

## No more naughty words

Django has historically provided (and enforced) a list of profanities. The comments app has enforced this list of profanities, preventing people from submitting comments that contained one of those profanities.

Unfortunately, the technique used to implement this profanities list was woefully naive, and prone to the [Scunthorpe problem](#). Improving the built-in filter to fix this problem would require significant effort, and since natural language processing isn't the normal domain of a web framework, we have “fixed” the problem by making the list of prohibited words an empty list.

If you want to restore the old behavior, simply put a `PROFANITIES_LIST` setting in your settings file that includes the words that you want to prohibit (see the [commit that implemented this change](#) if you want to see the list of words that was historically prohibited). However, if avoiding profanities is important to you, you would be well advised to seek out a better, less naive approach to the problem.

## Localflavor changes

Django 1.3 introduces the following backwards-incompatible changes to local flavors:

- Canada (ca) – The province “Newfoundland and Labrador” has had its province code updated to “NL”, rather than the older “NF”. In addition, the Yukon Territory has had its province code corrected to “YT”, instead of “YK”.
- Indonesia (id) – The province “Nanggroe Aceh Darussalam (NAD)” has been removed from the province list in favor of the new official designation “Aceh (ACE)”.
- United States of America (us) – The list of “states” used by `USStateField` has expanded to include Armed Forces postal codes. This is backwards-incompatible if you were relying on `USStateField` not including them.

## FormSet updates

In Django 1.3 `FormSet` creation behavior is modified slightly. Historically the class didn't make a distinction between not being passed data and being passed empty dictionary. This was inconsistent with behavior in other parts of the framework. Starting with 1.3 if you pass in empty dictionary the `FormSet` will raise a `ValidationError`.

For example with a `FormSet`:

```
>>> class ArticleForm(Form):
...     title = CharField()
...     pub_date = DateField()
>>> ArticleFormSet = formset_factory(ArticleForm)
```

the following code will raise a `ValidationError`:

```
>>> ArticleFormSet({})
Traceback (most recent call last):
...
ValidationError: [u'ManagementForm data is missing or has been tampered with']
```

if you need to instantiate an empty `FormSet`, don't pass in the data or use `None`:

```
>>> formset = ArticleFormSet()
>>> formset = ArticleFormSet(data=None)
```

## Callables in templates

Previously, a callable in a template would only be called automatically as part of the variable resolution process if it was retrieved via attribute lookup. This was an inconsistency that could result in confusing and unhelpful behavior:

```
>>> Template("{% user.get_full_name %}").render(Context({'user': user}))
u'Joe Bloggs'
>>> Template("{% full_name %}").render(Context({'full_name': user.get_full_name}))
u'&lt;bound method User.get_full_name of &lt;...&gt;'
```

This has been resolved in Django 1.3 - the result in both cases will be `u'Joe Bloggs'`. Although the previous behavior was not useful for a template language designed for web designers, and was never deliberately supported, it is possible that some templates may be broken by this change.

## Use of custom SQL to load initial data in tests

Django provides a custom SQL hooks as a way to inject hand-crafted SQL into the database synchronization process. One of the possible uses for this custom SQL is to insert data into your database. If your custom SQL contains `INSERT` statements, those insertions will be performed every time your database is synchronized. This includes the synchronization of any test databases that are created when you run a test suite.

However, in the process of testing the Django 1.3, it was discovered that this feature has never completely worked as advertised. When using database backends that don't support transactions, or when using a `TransactionTestCase`, data that has been inserted using custom SQL will not be visible during the testing process.

Unfortunately, there was no way to rectify this problem without introducing a backwards incompatibility. Rather than leave SQL-inserted initial data in an uncertain state, Django now enforces the policy that data inserted by custom SQL will *not* be visible during testing.

This change only affects the testing process. You can still use custom SQL to load data into your production database as part of the `syncdb` process. If you require data to exist during test conditions, you should either insert it using *test fixtures*, or using the `setUp()` method of your test case.

## Changed priority of translation loading

Work has been done to simplify, rationalize and properly document the algorithm used by Django at runtime to build translations from the different translations found on disk, namely:

For translatable literals found in Python code and templates ('django' gettext domain):

- Priorities of translations included with applications listed in the `INSTALLED_APPS` setting were changed. To provide a behavior consistent with other parts of Django that also use such setting (templates, etc.) now, when

building the translation that will be made available, the apps listed first have higher precedence than the ones listed later.

- Now it is possible to override the translations shipped with applications by using the `LOCALE_PATHS` setting whose translations have now higher precedence than the translations of `INSTALLED_APPS` applications. The relative priority among the values listed in this setting has also been modified so the paths listed first have higher precedence than the ones listed later.
- The `locale` subdirectory of the directory containing the settings, that usually coincides with and is known as the *project directory* is being deprecated in this release as a source of translations. (the precedence of these translations is intermediate between applications and `LOCALE_PATHS` translations). See the *corresponding deprecated features section* of this document.

For translatable literals found in JavaScript code (`'djangojs'` gettext domain):

- Similarly to the `'django'` domain translations: Overriding of translations shipped with applications by using the `LOCALE_PATHS` setting is now possible for this domain too. These translations have higher precedence than the translations of Python packages passed to the *javascript\_catalog view*. Paths listed first have higher precedence than the ones listed later.
- Translations under the `locale` subdirectory of the *project directory* have never been taken in account for JavaScript translations and remain in the same situation considering the deprecation of such location.

## Transaction management

When using managed transactions – that is, anything but the default autocommit mode – it is important when a transaction is marked as “dirty”. Dirty transactions are committed by the `commit_on_success` decorator or the `django.middleware.transaction.TransactionMiddleware`, and `commit_manually` forces them to be closed explicitly; clean transactions “get a pass”, which means they are usually rolled back at the end of a request when the connection is closed.

Until Django 1.3, transactions were only marked dirty when Django was aware of a modifying operation performed in them; that is, either some model was saved, some bulk update or delete was performed, or the user explicitly called `transaction.set_dirty()`. In Django 1.3, a transaction is marked dirty when *any* database operation is performed.

As a result of this change, you no longer need to set a transaction dirty explicitly when you execute raw SQL or use a data-modifying `SELECT`. However, you *do* need to explicitly close any read-only transactions that are being managed using `commit_manually()`. For example:

```
@transaction.commit_manually
def my_view(request, name):
    obj = get_object_or_404(MyObject, name__iexact=name)
    return render_to_response('template', {'object':obj})
```

Prior to Django 1.3, this would work without error. However, under Django 1.3, this will raise a `TransactionManagementError` because the read operation that retrieves the `MyObject` instance leaves the transaction in a dirty state.

## No password reset for inactive users

Prior to Django 1.3, inactive users were able to request a password reset email and reset their password. In Django 1.3 inactive users will receive the same message as a nonexistent account.

## Password reset view now accepts `from_email`

The `django.contrib.auth.views.password_reset()` view now accepts a `from_email` parameter, which is passed to the `password_reset_form`'s `save()` method as a keyword argument. If you are using this view with a custom password reset form, then you will need to ensure your form's `save()` method accepts this keyword argument.

## Features deprecated in 1.3

Django 1.3 deprecates some features from earlier releases. These features are still supported, but will be gradually phased out over the next few release cycles.

Code taking advantage of any of the features below will raise a `PendingDeprecationWarning` in Django 1.3. This warning will be silent by default, but may be turned on using Python's `warnings` module, or by running Python with a `-Wd` or `-Wall` flag.

In Django 1.4, these warnings will become a `DeprecationWarning`, which is *not* silent. In Django 1.5 support for these features will be removed entirely.

### See also:

For more details, see the documentation [Django's release process](#) and our [deprecation timeline](#).

## `mod_python` support

The `mod_python` library has not had a release since 2007 or a commit since 2008. The Apache Foundation board voted to remove `mod_python` from the set of active projects in its version control repositories, and its lead developer has shifted all of his efforts toward the lighter, slimmer, more stable, and more flexible `mod_wsgi` backend.

If you are currently using the `mod_python` request handler, you should redeploy your Django projects using another request handler. `mod_wsgi` is the request handler recommended by the Django project, but FastCGI is also supported. Support for `mod_python` deployment will be removed in Django 1.5.

## Function-based generic views

As a result of the introduction of class-based generic views, the function-based generic views provided by Django have been deprecated. The following modules and the views they contain have been deprecated:

- `django.views.generic.create_update`
- `django.views.generic.date_based`
- `django.views.generic.list_detail`
- `django.views.generic.simple`

## Test client response `template` attribute

Django's `test client` returns `Response` objects annotated with extra testing information. In Django versions prior to 1.3, this included a `template` attribute containing information about templates rendered in generating the response: either `None`, a single `Template` object, or a list of `Template` objects. This inconsistency in return values (sometimes a list, sometimes not) made the attribute difficult to work with.

In Django 1.3 the `template` attribute is deprecated in favor of a new `templates` attribute, which is always a list, even if it has only a single element or no elements.

## DjangoTestRunner

As a result of the introduction of support for unittest2, the features of `django.test.simple.DjangoTestRunner` (including fail-fast and Ctrl-C test termination) have been made redundant. In view of this redundancy, `DjangoTestRunner` has been turned into an empty placeholder class, and will be removed entirely in Django 1.5.

## Changes to `url` and `ssi`

Most template tags will allow you to pass in either constants or variables as arguments – for example:

```
{% extends "base.html" %}
```

allows you to specify a base template as a constant, but if you have a context variable `templ` that contains the value `base.html`:

```
{% extends templ %}
```

is also legal.

However, due to an accident of history, the `url` and `ssi` are different. These tags use the second, quoteless syntax, but interpret the argument as a constant. This means it isn't possible to use a context variable as the target of a `url` and `ssi` tag.

Django 1.3 marks the start of the process to correct this historical accident. Django 1.3 adds a new template library – `future` – that provides alternate implementations of the `url` and `ssi` template tags. This `future` library implements behavior that makes the handling of the first argument consistent with the handling of all other variables. So, an existing template that contains:

```
{% url sample %}
```

should be replaced with:

```
{% load url from future %}
{% url 'sample' %}
```

The tags implementing the old behavior have been deprecated, and in Django 1.5, the old behavior will be replaced with the new behavior. To ensure compatibility with future versions of Django, existing templates should be modified to use the new `future` libraries and syntax.

## Changes to the login methods of the admin

In previous version the admin app defined login methods in multiple locations and ignored the almost identical implementation in the already used auth app. A side effect of this duplication was the missing adoption of the changes made in [r12634](#) to support a broader set of characters for usernames.

This release refactors the admin's login mechanism to use a subclass of the `AuthenticationForm` instead of a manual form validation. The previously undocumented method `'django.contrib.admin.sites.AdminSite.display_login_form'` has been removed in favor of a new `login_form` attribute.

## reset and sqlreset management commands

Those commands have been deprecated. The `flush` and `sqlflush` commands can be used to delete everything. You can also use `ALTER TABLE` or `DROP TABLE` statements manually.

## GeoDjango

- The function-based `TEST_RUNNER` previously used to execute the GeoDjango test suite, `django.contrib.gis.tests.run_gis_tests`, was deprecated for the class-based runner, `django.contrib.gis.tests.GeoDjangoTestSuiteRunner`.
- Previously, calling `transform()` would silently do nothing when GDAL wasn't available. Now, a `GEOSException` is properly raised to indicate possible faulty application code. A warning is now raised if `transform()` is called when the SRID of the geometry is less than 0 or None.

### CZBirthNumberField.clean

Previously this field's `clean()` method accepted a second, `gender`, argument which allowed stronger validation checks to be made, however since this argument could never actually be passed from the Django form machinery it is now pending deprecation.

### CompatCookie

Previously, `django.http` exposed an undocumented `CompatCookie` class, which was a bugfix wrapper around the standard library `SimpleCookie`. As the fixes are moving upstream, this is now deprecated - you should use `from django.http import SimpleCookie` instead.

## Loading of *project-level* translations

This release of Django starts the deprecation process for inclusion of translations located under the so-called *project path* in the translation building process performed at runtime. The `LOCALE_PATHS` setting can be used for the same task by adding the filesystem path to a `locale` directory containing project-level translations to the value of that setting.

Rationale for this decision:

- The *project path* has always been a loosely defined concept (actually, the directory used for locating project-level translations is the directory containing the settings module) and there has been a shift in other parts of the framework to stop using it as a reference for location of assets at runtime.
- Detection of the `locale` subdirectory tends to fail when the deployment scenario is more complex than the basic one. e.g. it fails when the settings module is a directory (ticket #10765).
- There are potential strange development- and deployment-time problems like the fact that the `project_dir/locale/` subdir can generate spurious error messages when the project directory is added to the Python path (`manage.py runserver` does this) and then it clashes with the equally named standard library module, this is a typical warning message:

```
/usr/lib/python2.6/gettext.py:49: ImportWarning: Not importing directory '/path/
↳to/project/locale': missing __init__.py.
import locale, copy, os, re, struct, sys
```

- This location wasn't included in the translation building process for JavaScript literals. This deprecation removes such inconsistency.

### PermWrapper moved to `django.contrib.auth.context_processors`

In Django 1.2, we began the process of changing the location of the auth context processor from `django.core.context_processors` to `django.contrib.auth.context_processors`. However, the `PermWrapper` support class was mistakenly omitted from that migration. In Django 1.3, the `PermWrapper` class has also been moved to `django.contrib.auth.context_processors`, along with the `PermLookupDict` support class. The new classes are functionally identical to their old versions; only the module location has changed.

### Removal of `XMLField`

When Django was first released, Django included an `XMLField` that performed automatic XML validation for any field input. However, this validation function hasn't been performed since the introduction of `newforms`, prior to the 1.0 release. As a result, `XMLField` as currently implemented is functionally indistinguishable from a simple `TextField`.

For this reason, Django 1.3 has fast-tracked the deprecation of `XMLField` – instead of a two-release deprecation, `XMLField` will be removed entirely in Django 1.4.

It's easy to update your code to accommodate this change – just replace all uses of `XMLField` with `TextField`, and remove the `schema_path` keyword argument (if it is specified).

## 9.1.9 1.2 release

### Django 1.2.7 release notes

*September 10, 2011*

Welcome to Django 1.2.7!

This is the seventh bugfix/security release in the Django 1.2 series. It replaces Django 1.2.6 due to problems with the 1.2.6 release tarball. Django 1.2.7 is a recommended upgrade for all users of any Django release in the 1.2.X series.

For more information, see the [release advisory](#).

### Django 1.2.6 release notes

*September 9, 2011*

Welcome to Django 1.2.6!

This is the sixth bugfix/security release in the Django 1.2 series, fixing several security issues present in Django 1.2.5. Django 1.2.6 is a recommended upgrade for all users of any Django release in the 1.2.X series.

For a full list of issues addressed in this release, see the [security advisory](#).

### Django 1.2.5 release notes

Welcome to Django 1.2.5!

This is the fifth “bugfix” release in the Django 1.2 series, improving the stability and performance of the Django 1.2 codebase.

With four exceptions, Django 1.2.5 maintains backwards compatibility with Django 1.2.4. It also contains a number of fixes and other improvements. Django 1.2.5 is a recommended upgrade for any development or deployment currently using or targeting Django 1.2.

For full details on the new features, backwards incompatibilities, and deprecated features in the 1.2 branch, see the [Django 1.2 release notes](#).

## Backwards incompatible changes

### CSRF exception for AJAX requests

Django includes a CSRF-protection mechanism, which makes use of a token inserted into outgoing forms. Middleware then checks for the token's presence on form submission, and validates it.

Prior to Django 1.2.5, our CSRF protection made an exception for AJAX requests, on the following basis:

- Many AJAX toolkits add an X-Requested-With header when using XMLHttpRequest.
- Browsers have strict same-origin policies regarding XMLHttpRequest.
- In the context of a browser, the only way that a custom header of this nature can be added is with XMLHttpRequest.

Therefore, for ease of use, we did not apply CSRF checks to requests that appeared to be AJAX on the basis of the X-Requested-With header. The Ruby on Rails web framework had a similar exemption.

Recently, engineers at Google made members of the Ruby on Rails development team aware of a combination of browser plugins and redirects which can allow an attacker to provide custom HTTP headers on a request to any website. This can allow a forged request to appear to be an AJAX request, thereby defeating CSRF protection which trusts the same-origin nature of AJAX requests.

Michael Koziarski of the Rails team brought this to our attention, and we were able to produce a proof-of-concept demonstrating the same vulnerability in Django's CSRF handling.

To remedy this, Django will now apply full CSRF validation to all requests, regardless of apparent AJAX origin. This is technically backwards-incompatible, but the security risks have been judged to outweigh the compatibility concerns in this case.

Additionally, Django will now accept the CSRF token in the custom HTTP header X-CSRFToken, as well as in the form submission itself, for ease of use with popular JavaScript toolkits which allow insertion of custom headers into all AJAX requests.

Please see the [CSRF docs for example jQuery code](#) that demonstrates this technique, ensuring that you are looking at the documentation for your version of Django, as the exact code necessary is different for some older versions of Django.

### FileField no longer deletes files

In earlier Django versions, when a model instance containing a `FileField` was deleted, `FileField` took it upon itself to also delete the file from the backend storage. This opened the door to several potentially serious data-loss scenarios, including rolled-back transactions and fields on different models referencing the same file. In Django 1.2.5, `FileField` will never delete files from the backend storage. If you need cleanup of orphaned files, you'll need to handle it yourself (for instance, with a custom management command that can be run manually or scheduled to run periodically via e.g. cron).

## Use of custom SQL to load initial data in tests

Django provides a custom SQL hooks as a way to inject hand-crafted SQL into the database synchronization process. One of the possible uses for this custom SQL is to insert data into your database. If your custom SQL contains `INSERT` statements, those insertions will be performed every time your database is synchronized. This includes the synchronization of any test databases that are created when you run a test suite.

However, in the process of testing the Django 1.3, it was discovered that this feature has never completely worked as advertised. When using database backends that don't support transactions, or when using a `TransactionTestCase`, data that has been inserted using custom SQL will not be visible during the testing process.

Unfortunately, there was no way to rectify this problem without introducing a backwards incompatibility. Rather than leave SQL-inserted initial data in an uncertain state, Django now enforces the policy that data inserted by custom SQL will *not* be visible during testing.

This change only affects the testing process. You can still use custom SQL to load data into your production database as part of the `syncdb` process. If you require data to exist during test conditions, you should either insert it using *test fixtures*, or using the `setUp()` method of your test case.

## ModelAdmin.lookup\_allowed signature changed

Django 1.2.4 introduced a method `lookup_allowed` on `ModelAdmin`, to cope with a security issue (changeset [15033]). Although this method was never documented, it seems some people have overridden `lookup_allowed`, especially to cope with regressions introduced by that changeset. While the method is still undocumented and not marked as stable, it may be helpful to know that the signature of this function has changed.

## Django 1.2.4 release notes

Welcome to Django 1.2.4!

This is the fourth “bugfix” release in the Django 1.2 series, improving the stability and performance of the Django 1.2 codebase.

With one exception, Django 1.2.4 maintains backwards compatibility with Django 1.2.3. It also contains a number of fixes and other improvements. Django 1.2.4 is a recommended upgrade for any development or deployment currently using or targeting Django 1.2.

For full details on the new features, backwards incompatibilities, and deprecated features in the 1.2 branch, see the *Django 1.2 release notes*.

## Backwards incompatible changes

### Restricted filters in admin interface

The Django administrative interface, `django.contrib.admin`, supports filtering of displayed lists of objects by fields on the corresponding models, including across database-level relationships. This is implemented by passing lookup arguments in the querystring portion of the URL, and options on the `ModelAdmin` class allow developers to specify particular fields or relationships which will generate automatic links for filtering.

One historically-undocumented and -unofficially-supported feature has been the ability for a user with sufficient knowledge of a model's structure and the format of these lookup arguments to invent useful new filters on the fly by manipulating the querystring.

However, it has been demonstrated that this can be abused to gain access to information outside of an admin user's permissions; for example, an attacker with access to the admin and sufficient knowledge of model structure and

relations could construct query strings which – with repeated use of regular-expression lookups supported by the Django database API – expose sensitive information such as users’ password hashes.

To remedy this, `django.contrib.admin` will now validate that `querystring` lookup arguments either specify only fields on the model being viewed, or cross relations which have been explicitly whitelisted by the application developer using the pre-existing mechanism mentioned above. This is backwards-incompatible for any users relying on the prior ability to insert arbitrary lookups.

## One new feature

Ordinarily, a point release would not include new features, but in the case of Django 1.2.4, we have made an exception to this rule.

One of the bugs fixed in Django 1.2.4 involves a set of circumstances whereby a running a test suite on a multiple database configuration could cause the original source database (i.e., the actual production database) to be dropped, causing catastrophic loss of data. In order to provide a fix for this problem, it was necessary to introduce a new setting – `TEST_DEPENDENCIES` – that allows you to define any creation order dependencies in your database configuration.

Most users – even users with multiple-database configurations – need not be concerned about the data loss bug, or the manual configuration of `TEST_DEPENDENCIES`. See the [original problem report](#) documentation on *controlling the creation order of test databases* for details.

## GeoDjango

The function-based `TEST_RUNNER` previously used to execute the GeoDjango test suite, `django.contrib.gis.tests.run_gis_tests`, was finally deprecated in favor of a class-based test runner, `django.contrib.gis.tests.GeoDjangoTestSuiteRunner`, added in this release.

In addition, the GeoDjango test suite is now included when *running the Django test suite* with `runtests.py` and using *spatial database backends*.

## Django 1.2.3 release notes

Django 1.2.3 fixed a couple of release problems in the 1.2.2 release and was released two days after 1.2.2.

This release corrects the following problems:

- The [patch](#) applied for the security issue covered in Django 1.2.2 caused issues with non-ASCII responses using CSRF tokens.
- The patch also caused issues with some forms, most notably the user-editing forms in the Django administrative interface.
- The packaging manifest did not contain the full list of required files.

## Django 1.2.2 release notes

Welcome to Django 1.2.2!

This is the second “bugfix” release in the Django 1.2 series, improving the stability and performance of the Django 1.2 codebase.

Django 1.2.2 maintains backwards compatibility with Django 1.2.1, but contain a number of fixes and other improvements. Django 1.2.2 is a recommended upgrade for any development or deployment currently using or targeting Django 1.2.

For full details on the new features, backwards incompatibilities, and deprecated features in the 1.2 branch, see the [Django 1.2 release notes](#).

### One new feature

Ordinarily, a point release would not include new features, but in the case of Django 1.2.2, we have made an exception to this rule.

In order to test a bug fix that forms part of the 1.2.2 release, it was necessary to add a feature – the `enforce_csrf_checks` flag – to the *test client*. This flag forces the test client to perform full CSRF checks on forms. The default behavior of the test client hasn't changed, but if you want to do CSRF checks with the test client, it is now possible to do so.

### Django 1.2.1 release notes

Django 1.2.1 was released almost immediately after 1.2.0 to correct two small bugs: one was in the documentation packaging script, the other was a [bug](#) that affected datetime form field widgets when localization was enabled.

### Django 1.2 release notes

*May 17, 2010.*

Welcome to Django 1.2!

Nearly a year in the making, Django 1.2 packs an impressive list of *new features* and lots of bug fixes. These release notes cover the new features, as well as important changes you'll want to be aware of when upgrading from Django 1.1 or older versions.

### Overview

Django 1.2 introduces several large, important new features, including:

- Support for *multiple database connections* in a single Django instance.
- *Model validation* inspired by Django's form validation.
- Vastly *improved protection against Cross-Site Request Forgery (CSRF)*.
- A new *user "messages" framework* with support for cookie- and session-based message for both anonymous and authenticated users.
- Hooks for *object-level permissions, permissions for anonymous users, and more flexible username requirements*.
- Customization of email sending via *email backends*.
- New *"smart" if template tag* which supports comparison operators.

These are just the highlights; full details and a complete list of features *may be found below*.

#### See also:

[Django Advent](#) covered the release of Django 1.2 with a series of articles and tutorials that cover some of the new features in depth.

Wherever possible these features have been introduced in a backwards-compatible manner per *our API stability policy*.

However, a handful of features *have* changed in ways that, for some users, will be backwards-incompatible. The big changes are:

- Support for Python 2.3 has been dropped. See the full notes below.
- The new CSRF protection framework is not backwards-compatible with the old system. Users of the old system will not be affected until the old system is removed in Django 1.4.

However, upgrading to the new CSRF protection framework requires a few important backwards-incompatible changes, detailed in *CSRF Protection*, below.

- Authors of custom *Field* subclasses should be aware that a number of methods have had a change in prototype, detailed under *get\_db\_prep\_\*() methods on Field*, below.
- The internals of template tags have changed somewhat; authors of custom template tags that need to store state (e.g. custom control flow tags) should ensure that their code follows the new rules for *stateful template tags*
- The *user\_passes\_test()*, *login\_required()*, and *permission\_required()*, decorators from *django.contrib.auth* only apply to functions and no longer work on methods. There's a simple one-line fix *detailed below*.

Again, these are just the big features that will affect the most users. Users upgrading from previous versions of Django are heavily encouraged to consult the complete list of *backwards-incompatible changes* and the list of *deprecated features*.

## Python compatibility

While not a new feature, it's important to note that Django 1.2 introduces the first shift in our Python compatibility policy since Django's initial public debut. Previous Django releases were tested and supported on 2.x Python versions from 2.3 up; Django 1.2, however, drops official support for Python 2.3. As such, the minimum Python version required for Django is now 2.4, and Django is tested and supported on Python 2.4, 2.5 and 2.6, and will be supported on the as-yet-unreleased Python 2.7.

This change should affect only a small number of Django users, as most operating-system vendors today are shipping Python 2.4 or newer as their default version. If you're still using Python 2.3, however, you'll need to stick to Django 1.1 until you can upgrade; per *our support policy*, Django 1.1 will continue to receive security support until the release of Django 1.3.

A roadmap for Django's overall 2.x Python support, and eventual transition to Python 3.x, is currently being developed, and will be announced prior to the release of Django 1.3.

## What's new in Django 1.2

### Support for multiple databases

Django 1.2 adds the ability to use *more than one database* in your Django project. Queries can be issued at a specific database with the `using()` method on `QuerySet` objects. Individual objects can be saved to a specific database by providing a `using` argument when you call `save()`.

### Model validation

Model instances now have support for *validating their own data*, and both model and form fields now accept configurable lists of *validators* specifying reusable, encapsulated validation behavior. Note, however, that validation must still be performed explicitly. Simply invoking a model instance's `save()` method will not perform any validation of the instance's data.

## Improved CSRF protection

Django now has much improved protection against *Cross-Site Request Forgery (CSRF) attacks*. This type of attack occurs when a malicious website contains a link, a form button or some JavaScript that is intended to perform some action on your website, using the credentials of a logged-in user who visits the malicious site in their browser. A related type of attack, “login CSRF,” where an attacking site tricks a user’s browser into logging into a site with someone else’s credentials, is also covered.

## Messages framework

Django now includes a robust and configurable *messages framework* with built-in support for cookie- and session-based messaging, for both anonymous and authenticated clients. The messages framework replaces the deprecated user message API and allows you to temporarily store messages in one request and retrieve them for display in a subsequent request (usually the next one).

## Object-level permissions

A foundation for specifying permissions at the per-object level has been added. Although there is no implementation of this in core, a custom authentication backend can provide this implementation and it will be used by *django.contrib.auth.models.User*. See the *authentication docs* for more information.

## Permissions for anonymous users

If you provide a custom auth backend with `supports_anonymous_user` set to `True`, `AnonymousUser` will check the backend for permissions, just like `User` already did. This is useful for centralizing permission handling - apps can always delegate the question of whether something is allowed or not to the authorization/authentication backend. See the *authentication docs* for more details.

## Relaxed requirements for usernames

The built-in *User* model’s *username* field now allows a wider range of characters, including @, +, . and - characters.

## Email backends

You can now *configure the way that Django sends email*. Instead of using SMTP to send all email, you can now choose a configurable email backend to send messages. If your hosting provider uses a sandbox or some other non-SMTP technique for sending mail, you can now construct an email backend that will allow Django’s standard *mail sending methods* to use those facilities.

This also makes it easier to debug mail sending. Django ships with backend implementations that allow you to send email to a *file*, to the *console*, or to *memory*. You can even configure all email to be *thrown away*.

## “Smart” `if` tag

The *if* tag has been upgraded to be much more powerful. First, we’ve added support for comparison operators. No longer will you have to type:

```
{% ifnotequal a b %}
...
{% endifnotequal %}
```

You can now do this:

```
{% if a != b %}
...
{% endif %}
```

There's really no reason to use `{% ifequal %}` or `{% ifnotequal %}` anymore, unless you're the nostalgic type.

The operators supported are `==`, `!=`, `<`, `>`, `<=`, `>=`, `in` and `not in`, all of which work like the Python operators, in addition to `and`, `or` and `not`, which were already supported.

Also, filters may now be used in the `if` expression. For example:

```
<div
  {% if user.email|lower == message.recipient|lower %}
    class="highlight"
  {% endif %}
>{{ message }}</div>
```

## Template caching

In previous versions of Django, every time you rendered a template, it would be reloaded from disk. In Django 1.2, you can use a *cached template loader* to load templates once, then cache the result for every subsequent render. This can lead to a significant performance improvement if your templates are broken into lots of smaller subtemplates (using the `{% extends %}` or `{% include %}` tags).

As a side effect, it is now much easier to support non-Django template languages.

## Class-based template loaders

As part of the changes made to introduce *Template caching* and following a general trend in Django, the template loaders API has been modified to use template loading mechanisms that are encapsulated in Python classes as opposed to functions, the only method available until Django 1.1.

All the template loaders *shipped with Django* have been ported to the new API but they still implement the function-based API and the template core machinery still accepts function-based loaders (builtin or third party) so there is no immediate need to modify your `TEMPLATE_LOADERS` setting in existing projects, things will keep working if you leave it untouched up to and including the Django 1.3 release.

If you have developed your own custom template loaders we suggest to consider porting them to a class-based implementation because the code for backwards compatibility with function-based loaders starts its deprecation process in Django 1.2 and will be removed in Django 1.4. There is a description of the API these loader classes must implement in the template API reference and you can also examine the source code of the loaders shipped with Django.

## Natural keys in fixtures

Fixtures can now refer to remote objects using *Natural keys*. This lookup scheme is an alternative to the normal primary-key based object references in a fixture, improving readability and resolving problems referring to objects whose primary key value may not be predictable or known.

## Fast failure for tests

Both the `test` subcommand of `django-admin.py` and the `runtests.py` script used to run Django's own test suite now support a `--failfast` option. When specified, this option causes the test runner to exit after encountering a failure instead of continuing with the test run. In addition, the handling of `Ctrl-C` during a test run has been improved to trigger a graceful exit from the test run that reports details of the tests that were run before the interruption.

## BigIntegerField

Models can now use a 64-bit `BigIntegerField` type.

## Improved localization

Django's *internationalization framework* has been expanded with locale-aware formatting and form processing. That means, if enabled, dates and numbers on templates will be displayed using the format specified for the current locale. Django will also use localized formats when parsing data in forms. See *Format localization* for more details.

## readonly\_fields in ModelAdmin

`django.contrib.admin.ModelAdmin.readonly_fields` has been added to enable non-editable fields in add/change pages for models and inlines. Field and calculated values can be displayed alongside editable fields.

## Customizable syntax highlighting

You can now use a `DJANGO_COLORS` environment variable to modify or disable the colors used by `django-admin.py` to provide *syntax highlighting*.

## Syndication feeds as views

*Syndication feeds* can now be used directly as views in your *URLconf*. This means that you can maintain complete control over the URL structure of your feeds. Like any other view, feeds views are passed a `request` object, so you can do anything you would normally do with a view, like user based access control, or making a feed a named URL.

## GeoDjango

The most significant new feature for *GeoDjango* in 1.2 is support for multiple spatial databases. As a result, the following *spatial database backends* are now included:

- `django.contrib.gis.db.backends.postgis`
- `django.contrib.gis.db.backends.mysql`
- `django.contrib.gis.db.backends.oracle`
- `django.contrib.gis.db.backends.spatialite`

GeoDjango now supports the rich capabilities added in the PostGIS 1.5 release. New features include support for the *geography type* and enabling of *distance queries* with non-point geometries on geographic coordinate systems.

Support for 3D geometry fields was added, and may be enabled by setting the `dim` keyword to 3 in your `GeometryField`. The `Extent3D` aggregate and `extent3d()` `GeoQuerySet` method were added as a part of this feature.

The following `GeoQuerySet` methods are new in 1.2:

- `force_rhr()`
- `reverse_geom()`
- `geohash()`

The GEOS interface was updated to use thread-safe C library functions when available on the platform.

The GDAL interface now allows the user to set a `spatial_filter` on the features returned when iterating over a `Layer`.

Finally, *GeoDjango's documentation* is now included with Django's and is no longer hosted separately at [geodjango.org](http://geodjango.org).

## JavaScript-assisted handling of inline related objects in the admin

If a user has JavaScript enabled in their browser, the interface for inline objects in the admin now allows inline objects to be dynamically added and removed. Users without JavaScript-enabled browsers will see no change in the behavior of inline objects.

## New `now` template tag format specifier characters: `c` and `u`

The argument to the `now` has gained two new format characters: `c` to specify that a datetime value should be formatted in ISO 8601 format, and `u` that allows output of the microseconds part of a datetime or time value.

These are also available in others parts like the `date` and `time` template filters, the `humanize` template tag library and the new *format localization* framework.

## Backwards-incompatible changes in 1.2

Wherever possible the new features above have been introduced in a backwards-compatible manner per *our API stability policy*. This means that practically all existing code which worked with Django 1.1 will continue to work with Django 1.2; such code will, however, begin issuing warnings (see below for details).

However, a handful of features *have* changed in ways that, for some users, will be immediately backwards-incompatible. Those changes are detailed below.

## CSRF Protection

We've made large changes to the way CSRF protection works, detailed in *the CSRF documentation*. Here are the major changes you should be aware of:

- `CsrfResponseMiddleware` and `CsrfMiddleware` have been deprecated and will be removed completely in Django 1.4, in favor of a template tag that should be inserted into forms.
- All contrib apps use a `csrf_protect` decorator to protect the view. This requires the use of the `csrf_token` template tag in the template. If you have used custom templates for contrib views, you **MUST READ THE UPGRADE INSTRUCTIONS** to fix those templates.

### Documentation removed

The upgrade notes have been removed in current Django docs. Please refer to the docs for Django 1.3 or older to find these instructions.

- `CsrfViewMiddleware` is included in `MIDDLEWARE_CLASSES` by default. This turns on CSRF protection by default, so views that accept POST requests need to be written to work with the middleware. Instructions on how to do this are found in the CSRF docs.
- All of the CSRF has moved from contrib to core (with backwards compatible imports in the old locations, which are deprecated and will cease to be supported in Django 1.4).

### `get_db_prep_*()` methods on `Field`

Prior to Django 1.2, a custom `Field` had the option of defining several functions to support conversion of Python values into database-compatible values. A custom field might look something like:

```
class CustomModelField(models.Field):
    # ...
    def db_type(self):
        # ...

    def get_db_prep_save(self, value):
        # ...

    def get_db_prep_value(self, value):
        # ...

    def get_db_prep_lookup(self, lookup_type, value):
        # ...
```

In 1.2, these three methods have undergone a change in prototype, and two extra methods have been introduced:

```
class CustomModelField(models.Field):
    # ...

    def db_type(self, connection):
        # ...

    def get_prep_value(self, value):
        # ...

    def get_prep_lookup(self, lookup_type, value):
        # ...

    def get_db_prep_save(self, value, connection):
        # ...

    def get_db_prep_value(self, value, connection, prepared=False):
        # ...

    def get_db_prep_lookup(self, lookup_type, value, connection, prepared=False):
        # ...
```

These changes are required to support multiple databases – `db_type` and `get_db_prep_*` can no longer make any assumptions regarding the database for which it is preparing. The `connection` argument now provides the

preparation methods with the specific connection for which the value is being prepared.

The two new methods exist to differentiate general data-preparation requirements from requirements that are database-specific. The `prepared` argument is used to indicate to the database-preparation methods whether generic value preparation has been performed. If an unprepared (i.e., `prepared=False`) value is provided to the `get_db_prep_*()` calls, they should invoke the corresponding `get_prep_*()` calls to perform generic data preparation.

We've provided conversion functions that will transparently convert functions adhering to the old prototype into functions compatible with the new prototype. However, these conversion functions will be removed in Django 1.4, so you should upgrade your `Field` definitions to use the new prototype as soon as possible.

If your `get_db_prep_*()` methods made no use of the database connection, you should be able to upgrade by renaming `get_db_prep_value()` to `get_prep_value()` and `get_db_prep_lookup()` to `get_prep_lookup()`. If you require database specific conversions, then you will need to provide an implementation `get_db_prep_*` that uses the `connection` argument to resolve database-specific values.

## Stateful template tags

Template tags that store rendering state on their `Node` subclass have always been vulnerable to thread-safety and other issues; as of Django 1.2, however, they may also cause problems when used with the new *cached template loader*.

All of the built-in Django template tags are safe to use with the cached loader, but if you're using custom template tags that come from third party packages, or from your own code, you should ensure that the `Node` implementation for each tag is thread-safe. For more information, see *template tag thread safety considerations*.

You may also need to update your templates if you were relying on the implementation of Django's template tags *not* being thread safe. The *cycle* tag is the most likely to be affected in this way, especially when used in conjunction with the *include* tag. Consider the following template fragment:

```
{% for object in object_list %}
    {% include "subtemplate.html" %}
{% endfor %}
```

with a `subtemplate.html` that reads:

```
{% cycle 'even' 'odd' %}
```

Using the non-thread-safe, pre-Django 1.2 renderer, this would output:

```
even odd even odd ...
```

Using the thread-safe Django 1.2 renderer, you will instead get:

```
even even even even ...
```

This is because each rendering of the *include* tag is an independent rendering. When the *cycle* tag was not thread safe, the state of the *cycle* tag would leak between multiple renderings of the same *include*. Now that the *cycle* tag is thread safe, this leakage no longer occurs.

## `user_passes_test`, `login_required` and `permission_required`

`django.contrib.auth.decorators` provides the decorators `login_required`, `permission_required` and `user_passes_test`. Previously it was possible to use these decorators both on functions (where the first argument is 'request') and on methods (where the first argument is 'self', and the

second argument is 'request'). Unfortunately, flaws were discovered in the code supporting this: it only works in limited circumstances, and produces errors that are very difficult to debug when it does not work.

For this reason, the 'auto adapt' behavior has been removed, and if you are using these decorators on methods, you will need to manually apply `django.utils.decorators.method_decorator()` to convert the decorator to one that works with methods. For example, you would change code from this:

```
class MyClass(object):

    @login_required
    def my_view(self, request):
        pass
```

to this:

```
from django.utils.decorators import method_decorator

class MyClass(object):

    @method_decorator(login_required)
    def my_view(self, request):
        pass
```

or:

```
from django.utils.decorators import method_decorator

login_required_m = method_decorator(login_required)

class MyClass(object):

    @login_required_m
    def my_view(self, request):
        pass
```

For those of you who've been following the development trunk, this change also applies to other decorators introduced since 1.1, including `csrf_protect`, `cache_control` and anything created using `decorator_from_middleware`.

## if tag changes

Due to new features in the `if` template tag, it no longer accepts 'and', 'or' and 'not' as valid **variable** names. Previously, these strings could be used as variable names. Now, the keyword status is always enforced, and template code such as `{% if not %}` or `{% if and %}` will throw a `TemplateSyntaxError`. Also, `in` is a new keyword and so is not a valid variable name in this tag.

## LazyObject

`LazyObject` is an undocumented-but-often-used utility class used for lazily wrapping other objects of unknown type.

In Django 1.1 and earlier, it handled introspection in a non-standard way, depending on wrapped objects implementing a public method named `get_all_members()`. Since this could easily lead to name clashes, it has been changed to use the standard Python introspection method, involving `__members__` and `__dir__()`.

If you used `LazyObject` in your own code and implemented the `get_all_members()` method for wrapped objects, you'll need to make a couple of changes:

First, if your class does not have special requirements for introspection (i.e., you have not implemented `__getattr__()` or other methods that allow for attributes not discoverable by normal mechanisms), you can simply remove the `get_all_members()` method. The default implementation on `LazyObject` will do the right thing.

If you have more complex requirements for introspection, first rename the `get_all_members()` method to `__dir__()`. This is the standard introspection method for Python 2.6 and above. If you require support for Python versions earlier than 2.6, add the following code to the class:

```
__members__ = property(lambda self: self.__dir__())
```

### `__dict__` on model instances

Historically, the `__dict__` attribute of a model instance has only contained attributes corresponding to the fields on a model.

In order to support multiple database configurations, Django 1.2 has added a `_state` attribute to object instances. This attribute will appear in `__dict__` for a model instance. If your code relies on iterating over `__dict__` to obtain a list of fields, you must now be prepared to handle or filter out the `_state` attribute.

### Test runner exit status code

The exit status code of the test runners (`tests/runtests.py` and `python manage.py test`) no longer represents the number of failed tests, because a failure of 256 or more tests resulted in a wrong exit status code. The exit status code for the test runner is now 0 for success (no failing tests) and 1 for any number of test failures. If needed, the number of test failures can be found at the end of the test runner's output.

### Cookie encoding

To fix bugs with cookies in Internet Explorer, Safari, and possibly other browsers, our encoding of cookie values was changed so that the comma and semicolon are treated as non-safe characters, and are therefore encoded as `\054` and `\073` respectively. This could produce backwards incompatibilities, especially if you are storing comma or semicolon in cookies and have JavaScript code that parses and manipulates cookie values client-side.

### `ModelForm.is_valid()` and `ModelForm.errors`

Much of the validation work for `ModelForms` has been moved down to the model level. As a result, the first time you call `ModelForm.is_valid()`, access `ModelForm.errors` or otherwise trigger form validation, your model will be cleaned in-place. This conversion used to happen when the model was saved. If you need an unmodified instance of your model, you should pass a copy to the `ModelForm` constructor.

### `BooleanField` on MySQL

In previous versions of Django, a model's `BooleanField` under MySQL would return its value as either 1 or 0, instead of `True` or `False`; for most people this wasn't a problem because `bool` is a subclass of `int` in Python. In Django 1.2, however, `BooleanField` on MySQL correctly returns a real `bool`. The only time this should ever be an issue is if you were expecting the `repr` of a `BooleanField` to print 1 or 0.

## Changes to the interpretation of `max_num` in FormSets

As part of enhancements made to the handling of FormSets, the default value and interpretation of the `max_num` parameter to the `django.forms.formsets.formset_factory()` and `django.forms.models.modelformset_factory()` functions has changed slightly. This change also affects the way the `max_num` argument is used for inline admin objects.

Previously, the default value for `max_num` was 0 (zero). FormSets then used the boolean value of `max_num` to determine if a limit was to be imposed on the number of generated forms. The default value of 0 meant that there was no default limit on the number of forms in a FormSet.

Starting with 1.2, the default value for `max_num` has been changed to `None`, and FormSets will differentiate between a value of `None` and a value of 0. A value of `None` indicates that no limit on the number of forms is to be imposed; a value of 0 indicates that a maximum of 0 forms should be imposed. This doesn't necessarily mean that no forms will be displayed – see the [ModelFormSet documentation](#) for more details.

If you were manually specifying a value of 0 for `max_num`, you will need to update your FormSet and/or admin definitions.

### See also:

[JavaScript-assisted handling of inline related objects in the admin](#)

## `email_re`

An undocumented regular expression for validating email addresses has been moved from `django.form.fields` to `django.core.validators`. You will need to update your imports if you are using it.

## Features deprecated in 1.2

Finally, Django 1.2 deprecates some features from earlier releases. These features are still supported, but will be gradually phased out over the next few release cycles.

Code taking advantage of any of the features below will raise a `PendingDeprecationWarning` in Django 1.2. This warning will be silent by default, but may be turned on using Python's `warnings` module, or by running Python with a `-Wd` or `-Wall` flag.

In Django 1.3, these warnings will become a `DeprecationWarning`, which is *not* silent. In Django 1.4 support for these features will be removed entirely.

### See also:

For more details, see the documentation [Django's release process](#) and our [deprecation timeline](#).

## Specifying databases

Prior to Django 1.2, Django used a number of settings to control access to a single database. Django 1.2 introduces support for multiple databases, and as a result the way you define database settings has changed.

Any existing Django settings file will continue to work as expected until Django 1.4. Until then, old-style database settings will be automatically translated to the new-style format.

In the old-style (pre 1.2) format, you had a number of `DATABASE_` settings in your settings file. For example:

```
DATABASE_NAME = 'test_db'
DATABASE_ENGINE = 'postgresql_psycopg2'
DATABASE_USER = 'myusername'
DATABASE_PASSWORD = 's3krit'
```

These settings are now in a dictionary named `DATABASES`. Each item in the dictionary corresponds to a single database connection, with the name `'default'` describing the default database connection. The setting names have also been shortened. The previous sample settings would now look like this:

```
DATABASES = {
    'default': {
        'NAME': 'test_db',
        'ENGINE': 'django.db.backends.postgresql_psycopg2',
        'USER': 'myusername',
        'PASSWORD': 's3krit',
    }
}
```

This affects the following settings:

Old setting	New Setting
<code>DATABASE_ENGINE</code>	<code>ENGINE</code>
<code>DATABASE_HOST</code>	<code>HOST</code>
<code>DATABASE_NAME</code>	<code>NAME</code>
<code>DATABASE_OPTIONS</code>	<code>OPTIONS</code>
<code>DATABASE_PASSWORD</code>	<code>PASSWORD</code>
<code>DATABASE_PORT</code>	<code>PORT</code>
<code>DATABASE_USER</code>	<code>USER</code>
<code>TEST_DATABASE_CHARSET</code>	<code>TEST_CHARSET</code>
<code>TEST_DATABASE_COLLATION</code>	<code>TEST_COLLATION</code>
<code>TEST_DATABASE_NAME</code>	<code>TEST_NAME</code>

These changes are also required if you have manually created a database connection using `DatabaseWrapper()` from your database backend of choice.

In addition to the change in structure, Django 1.2 removes the special handling for the built-in database backends. All database backends must now be specified by a fully qualified module name (i.e., `django.db.backends.postgresql_psycopg2`, rather than just `postgresql_psycopg2`).

### postgresql database backend

The `psycopg1` library has not been updated since October 2005. As a result, the `postgresql` database backend, which uses this library, has been deprecated.

If you are currently using the `postgresql` backend, you should migrate to using the `postgresql_psycopg2` backend. To update your code, install the `psycopg2` library and change the `ENGINE` setting to use `django.db.backends.postgresql_psycopg2`.

### CSRF response-rewriting middleware

`CsrfResponseMiddleware`, the middleware that automatically inserted CSRF tokens into POST forms in outgoing pages, has been deprecated in favor of a template tag method (see above), and will be removed completely in Django 1.4. `CsrfMiddleware`, which includes the functionality of `CsrfResponseMiddleware` and `CsrfViewMiddleware`, has likewise been deprecated.

Also, the CSRF module has moved from contrib to core, and the old imports are deprecated, as described in the upgrading notes.

## Documentation removed

The upgrade notes have been removed in current Django docs. Please refer to the docs for Django 1.3 or older to find these instructions.

---

## SMTPConnection

The `SMTPConnection` class has been deprecated in favor of a generic email backend API. Old code that explicitly instantiated an instance of an `SMTPConnection`:

```
from django.core.mail import SMTPConnection
connection = SMTPConnection()
messages = get_notification_email()
connection.send_messages(messages)
```

...should now call `get_connection()` to instantiate a generic email connection:

```
from django.core.mail import get_connection
connection = get_connection()
messages = get_notification_email()
connection.send_messages(messages)
```

Depending on the value of the `EMAIL_BACKEND` setting, this may not return an SMTP connection. If you explicitly require an SMTP connection with which to send email, you can explicitly request an SMTP connection:

```
from django.core.mail import get_connection
connection = get_connection('django.core.mail.backends.smtp.EmailBackend')
messages = get_notification_email()
connection.send_messages(messages)
```

If your call to construct an instance of `SMTPConnection` required additional arguments, those arguments can be passed to the `get_connection()` call:

```
connection = get_connection('django.core.mail.backends.smtp.EmailBackend', hostname=
↳ 'localhost', port=1234)
```

## User Messages API

The API for storing messages in the user `Message` model (via `user.message_set.create`) is now deprecated and will be removed in Django 1.4 according to the standard *release process*.

To upgrade your code, you need to replace any instances of this:

```
user.message_set.create('a message')
```

...with the following:

```
from django.contrib import messages
messages.add_message(request, messages.INFO, 'a message')
```

Additionally, if you make use of the method, you need to replace the following:

```
for message in user.get_and_delete_messages():
    ...
```

...with:

```
from django.contrib import messages
for message in messages.get_messages(request):
    ...
```

For more information, see the full [messages documentation](#). You should begin to update your code to use the new API immediately.

## Date format helper functions

`django.utils.translation.get_date_formats()` and `django.utils.translation.get_partial_date_formats()` have been deprecated in favor of the appropriate calls to `django.utils.formats.get_format()`, which is locale-aware when `USE_L10N` is set to `True`, and falls back to default settings if set to `False`.

To get the different date formats, instead of writing this:

```
from django.utils.translation import get_date_formats
date_format, datetime_format, time_format = get_date_formats()
```

...use:

```
from django.utils import formats
date_format = formats.get_format('DATE_FORMAT')
datetime_format = formats.get_format('DATETIME_FORMAT')
time_format = formats.get_format('TIME_FORMAT')
```

Or, when directly formatting a date value:

```
from django.utils import formats
value_formatted = formats.date_format(value, 'DATETIME_FORMAT')
```

The same applies to the globals found in `django.forms.fields`:

- `DEFAULT_DATE_INPUT_FORMATS`
- `DEFAULT_TIME_INPUT_FORMATS`
- `DEFAULT_DATETIME_INPUT_FORMATS`

Use `django.utils.formats.get_format()` to get the appropriate formats.

## Function-based test runners

Django 1.2 changes the test runner tools to use a class-based approach. Old style function-based test runners will still work, but should be updated to use the new [class-based runners](#).

## Feed in `django.contrib.syndication.feeds`

The `django.contrib.syndication.feeds.Feed` class has been replaced by the `django.contrib.syndication.views.Feed` class. The old `feeds.Feed` class is deprecated, and will be removed in Django

1.4.

The new class has an almost identical API, but allows instances to be used as views. For example, consider the use of the old framework in the following *URLconf*:

```
from django.conf.urls.defaults import *
from myproject.feeds import LatestEntries, LatestEntriesByCategory

feeds = {
    'latest': LatestEntries,
    'categories': LatestEntriesByCategory,
}

urlpatterns = patterns('',
    # ...
    (r'^feeds/(?P<url>.*)/$', 'django.contrib.syndication.views.feed',
     {'feed_dict': feeds}),
    # ...
)
```

Using the new Feed class, these feeds can be deployed directly as views:

```
from django.conf.urls.defaults import *
from myproject.feeds import LatestEntries, LatestEntriesByCategory

urlpatterns = patterns('',
    # ...
    (r'^feeds/latest/$', LatestEntries()),
    (r'^feeds/categories/(?P<category_id>\d+)/$', LatestEntriesByCategory()),
    # ...
)
```

If you currently use the `feed()` view, the `LatestEntries` class would often not need to be modified apart from subclassing the new `Feed` class. The exception is if Django was automatically working out the name of the template to use to render the feed's description and title elements (if you were not specifying the `title_template` and `description_template` attributes). You should ensure that you always specify `title_template` and `description_template` attributes, or provide `item_title()` and `item_description()` methods.

However, `LatestEntriesByCategory` uses the `get_object()` method with the `bits` argument to specify a specific category to show. In the new `Feed` class, `get_object()` method takes a request and arguments from the URL, so it would look like this:

```
from django.contrib.syndication.views import Feed
from django.shortcuts import get_object_or_404
from myproject.models import Category

class LatestEntriesByCategory(Feed):
    def get_object(self, request, category_id):
        return get_object_or_404(Category, id=category_id)

    # ...
```

Additionally, the `get_feed()` method on `Feed` classes now take different arguments, which may impact you if you use the `Feed` classes directly. Instead of just taking an optional `url` argument, it now takes two arguments: the object returned by its own `get_object()` method, and the current request object.

To take into account `Feed` classes not being initialized for each request, the `__init__()` method now takes no arguments by default. Previously it would have taken the `slug` from the URL and the `request` object.

In accordance with [RSS best practices](#), RSS feeds will now include an `atom:link` element. You may need to update your tests to take this into account.

For more information, see the full [syndication framework documentation](#).

## Technical message IDs

Up to version 1.1 Django used technical message IDs to provide localizers the possibility to translate date and time formats. They were translatable *translation strings* that could be recognized because they were all upper case (for example `DATETIME_FORMAT`, `DATE_FORMAT`, `TIME_FORMAT`). They have been deprecated in favor of the new *Format localization* infrastructure that allows localizers to specify that information in a `formats.py` file in the corresponding `django/conf/locale/<locale name>/` directory.

## GeoDjango

To allow support for multiple databases, the GeoDjango database internals were changed substantially. The largest backwards-incompatible change is that the module `django.contrib.gis.db.backend` was renamed to `django.contrib.gis.db.backends`, where the full-fledged *spatial database backends* now exist. The following sections provide information on the most-popular APIs that were affected by these changes.

### SpatialBackend

Prior to the creation of the separate spatial backends, the `django.contrib.gis.db.backend.SpatialBackend` object was provided as an abstraction to introspect on the capabilities of the spatial database. All of the attributes and routines provided by `SpatialBackend` are now a part of the `ops` attribute of the database backend.

The old module `django.contrib.gis.db.backend` is still provided for backwards-compatibility access to a `SpatialBackend` object, which is just an alias to the `ops` module of the *default* spatial database connection.

Users that were relying on undocumented modules and objects within `django.contrib.gis.db.backend`, rather the abstractions provided by `SpatialBackend`, are required to modify their code. For example, the following import which would work in 1.1 and below:

```
from django.contrib.gis.db.backend.postgis import PostGISAdaptor
```

Would need to be changed:

```
from django.db import connection
PostGISAdaptor = connection.ops.Adapter
```

### SpatialRefSys and GeometryColumns models

In previous versions of GeoDjango, `django.contrib.gis.db.models` had `SpatialRefSys` and `GeometryColumns` models for querying the OGC spatial metadata tables `spatial_ref_sys` and `geometry_columns`, respectively.

While these aliases are still provided, they are only for the *default* database connection and exist only if the default connection is using a supported spatial database backend.

**Note:** Because the table structure of the OGC spatial metadata tables differs across spatial databases, the `SpatialRefSys` and `GeometryColumns` models can no longer be associated with the `gis` application name. Thus, no models will be returned when using the `get_models` method in the following example:

```
>>> from django.db.models import get_app, get_models
>>> get_models(get_app('gis'))
[]
```

To get the correct `SpatialRefSys` and `GeometryColumns` for your spatial database use the methods provided by the spatial backend:

```
>>> from django.db import connections
>>> SpatialRefSys = connections['my_spatialite'].ops.spatial_ref_sys()
>>> GeometryColumns = connections['my_postgis'].ops.geometry_columns()
```

**Note:** When using the models returned from the `spatial_ref_sys()` and `geometry_columns()` method, you'll still need to use the correct database alias when querying on the non-default connection. In other words, to ensure that the models in the example above use the correct database:

```
sr_qs = SpatialRefSys.objects.using('my_spatialite').filter(...)
gc_qs = GeometryColumns.objects.using('my_postgis').filter(...)
```

---

## Language code `no`

The currently used language code for Norwegian Bokmål `no` is being replaced by the more common language code `nb`.

## Function-based template loaders

Django 1.2 changes the template loading mechanism to use a class-based approach. Old style function-based template loaders will still work, but should be updated to use the new class-based template loaders.

## 9.1.10 1.1 release

### Django 1.1.4 release notes

Welcome to Django 1.1.4!

This is the fourth “bugfix” release in the Django 1.1 series, improving the stability and performance of the Django 1.1 codebase.

With one exception, Django 1.1.4 maintains backwards compatibility with Django 1.1.3. It also contains a number of fixes and other improvements. Django 1.1.4 is a recommended upgrade for any development or deployment currently using or targeting Django 1.1.

For full details on the new features, backwards incompatibilities, and deprecated features in the 1.1 branch, see the [Django 1.1 release notes](#).

## Backwards incompatible changes

### CSRF exception for AJAX requests

Django includes a CSRF-protection mechanism, which makes use of a token inserted into outgoing forms. Middleware then checks for the token's presence on form submission, and validates it.

Prior to Django 1.2.5, our CSRF protection made an exception for AJAX requests, on the following basis:

- Many AJAX toolkits add an X-Requested-With header when using XMLHttpRequest.
- Browsers have strict same-origin policies regarding XMLHttpRequest.
- In the context of a browser, the only way that a custom header of this nature can be added is with XMLHttpRequest.

Therefore, for ease of use, we did not apply CSRF checks to requests that appeared to be AJAX on the basis of the X-Requested-With header. The Ruby on Rails web framework had a similar exemption.

Recently, engineers at Google made members of the Ruby on Rails development team aware of a combination of browser plugins and redirects which can allow an attacker to provide custom HTTP headers on a request to any website. This can allow a forged request to appear to be an AJAX request, thereby defeating CSRF protection which trusts the same-origin nature of AJAX requests.

Michael Koziarski of the Rails team brought this to our attention, and we were able to produce a proof-of-concept demonstrating the same vulnerability in Django's CSRF handling.

To remedy this, Django will now apply full CSRF validation to all requests, regardless of apparent AJAX origin. This is technically backwards-incompatible, but the security risks have been judged to outweigh the compatibility concerns in this case.

Additionally, Django will now accept the CSRF token in the custom HTTP header X-CSRFToken, as well as in the form submission itself, for ease of use with popular JavaScript toolkits which allow insertion of custom headers into all AJAX requests.

Please see the *CSRF docs for example jQuery code* that demonstrates this technique, ensuring that you are looking at the documentation for your version of Django, as the exact code necessary is different for some older versions of Django.

### Django 1.1.3 release notes

Welcome to Django 1.1.3!

This is the third "bugfix" release in the Django 1.1 series, improving the stability and performance of the Django 1.1 codebase.

With one exception, Django 1.1.3 maintains backwards compatibility with Django 1.1.2. It also contains a number of fixes and other improvements. Django 1.1.2 is a recommended upgrade for any development or deployment currently using or targeting Django 1.1.

For full details on the new features, backwards incompatibilities, and deprecated features in the 1.1 branch, see the *Django 1.1 release notes*.

## Backwards incompatible changes

### Restricted filters in admin interface

The Django administrative interface, `django.contrib.admin`, supports filtering of displayed lists of objects by fields on the corresponding models, including across database-level relationships. This is implemented by passing lookup arguments in the querystring portion of the URL, and options on the `ModelAdmin` class allow developers to specify particular fields or relationships which will generate automatic links for filtering.

One historically-undocumented and -unofficially-supported feature has been the ability for a user with sufficient knowledge of a model's structure and the format of these lookup arguments to invent useful new filters on the fly by manipulating the querystring.

However, it has been demonstrated that this can be abused to gain access to information outside of an admin user's permissions; for example, an attacker with access to the admin and sufficient knowledge of model structure and relations could construct query strings which – with repeated use of regular-expression lookups supported by the Django database API – expose sensitive information such as users' password hashes.

To remedy this, `django.contrib.admin` will now validate that querystring lookup arguments either specify only fields on the model being viewed, or cross relations which have been explicitly whitelisted by the application developer using the pre-existing mechanism mentioned above. This is backwards-incompatible for any users relying on the prior ability to insert arbitrary lookups.

### Django 1.1.2 release notes

Welcome to Django 1.1.2!

This is the second “bugfix” release in the Django 1.1 series, improving the stability and performance of the Django 1.1 codebase.

Django 1.1.2 maintains backwards compatibility with Django 1.1.0, but contain a number of fixes and other improvements. Django 1.1.2 is a recommended upgrade for any development or deployment currently using or targeting Django 1.1.

For full details on the new features, backwards incompatibilities, and deprecated features in the 1.1 branch, see the *Django 1.1 release notes*.

### Backwards-incompatible changes in 1.1.2

#### Test runner exit status code

The exit status code of the test runners (`tests/runtests.py` and `python manage.py test`) no longer represents the number of failed tests, since a failure of 256 or more tests resulted in a wrong exit status code. The exit status code for the test runner is now 0 for success (no failing tests) and 1 for any number of test failures. If needed, the number of test failures can be found at the end of the test runner's output.

#### Cookie encoding

To fix bugs with cookies in Internet Explorer, Safari, and possibly other browsers, our encoding of cookie values was changed so that the characters comma and semi-colon are treated as non-safe characters, and are therefore encoded as `\054` and `\073` respectively. This could produce backwards incompatibilities, especially if you are storing comma or semi-colon in cookies and have JavaScript code that parses and manipulates cookie values client-side.

## One new feature

Ordinarily, a point release would not include new features, but in the case of Django 1.1.2, we have made an exception to this rule. Django 1.2 (the next major release of Django) will contain a feature that will improve protection against Cross-Site Request Forgery (CSRF) attacks. This feature requires the use of a new `csrf_token` template tag in all forms that Django renders.

To make it easier to support both 1.1.X and 1.2.X versions of Django with the same templates, we have decided to introduce the `csrf_token` template tag to the 1.1.X branch. In the 1.1.X branch, `csrf_token` does nothing - it has no effect on templates or form processing. However, it means that the same template will work with Django 1.2.

## Django 1.1 release notes

July 29, 2009

Welcome to Django 1.1!

Django 1.1 includes a number of nifty *new features*, lots of bug fixes, and an easy upgrade path from Django 1.0.

### Backwards-incompatible changes in 1.1

Django has a policy of *API stability*. This means that, in general, code you develop against Django 1.0 should continue to work against 1.1 unchanged. However, we do sometimes make backwards-incompatible changes if they're necessary to resolve bugs, and there are a handful of such (minor) changes between Django 1.0 and Django 1.1.

Before upgrading to Django 1.1 you should double-check that the following changes don't impact you, and upgrade your code if they do.

### Changes to constraint names

Django 1.1 modifies the method used to generate database constraint names so that names are consistent regardless of machine word size. This change is backwards incompatible for some users.

If you are using a 32-bit platform, you're off the hook; you'll observe no differences as a result of this change.

However, **users on 64-bit platforms may experience some problems** using the `reset` management command. Prior to this change, 64-bit platforms would generate a 64-bit, 16 character digest in the constraint name; for example:

```
ALTER TABLE myapp_sometable ADD CONSTRAINT object_id_refs_id_5e8f10c132091d1e FOREIGN_↵  
↵KEY ...
```

Following this change, all platforms, regardless of word size, will generate a 32-bit, 8 character digest in the constraint name; for example:

```
ALTER TABLE myapp_sometable ADD CONSTRAINT object_id_refs_id_32091d1e FOREIGN KEY ...
```

As a result of this change, you will not be able to use the `reset` management command on any table made by a 64-bit machine. This is because the new generated name will not match the historically generated name; as a result, the SQL constructed by the `reset` command will be invalid.

If you need to reset an application that was created with 64-bit constraints, you will need to manually drop the old constraint prior to invoking `reset`.

## Test cases are now run in a transaction

Django 1.1 runs tests inside a transaction, allowing better test performance (see *test performance improvements* for details).

This change is slightly backwards incompatible if existing tests need to test transactional behavior, if they rely on invalid assumptions about the test environment, or if they require a specific test case ordering.

For these cases, *TransactionTestCase* can be used instead. This is just a quick fix to get around test case errors revealed by the new rollback approach; in the long-term tests should be rewritten to correct the test case.

## Removed `SetRemoteAddrFromForwardedFor` middleware

For convenience, Django 1.0 included an optional middleware class – `django.middleware.http.SetRemoteAddrFromForwardedFor` – which updated the value of `REMOTE_ADDR` based on the `HTTP X-Forwarded-For` header commonly set by some proxy configurations.

It has been demonstrated that this mechanism cannot be made reliable enough for general-purpose use, and that (despite documentation to the contrary) its inclusion in Django may lead application developers to assume that the value of `REMOTE_ADDR` is “safe” or in some way reliable as a source of authentication.

While not directly a security issue, we’ve decided to remove this middleware with the Django 1.1 release. It has been replaced with a class that does nothing other than raise a `DeprecationWarning`.

If you’ve been relying on this middleware, the easiest upgrade path is:

- Examine the code as it existed before it was removed.
- Verify that it works correctly with your upstream proxy, modifying it to support your particular proxy (if necessary).
- Introduce your modified version of `SetRemoteAddrFromForwardedFor` as a piece of middleware in your own project.

## Names of uploaded files are available later

In Django 1.0, files uploaded and stored in a model’s `FileField` were saved to disk before the model was saved to the database. This meant that the actual file name assigned to the file was available before saving. For example, it was available in a model’s pre-save signal handler.

In Django 1.1 the file is saved as part of saving the model in the database, so the actual file name used on disk cannot be relied on until *after* the model has been saved.

## Changes to how model formsets are saved

In Django 1.1, `BaseModelFormSet` now calls `ModelForm.save()`.

This is backwards-incompatible if you were modifying `self.initial` in a model formset’s `__init__`, or if you relied on the internal `_total_form_count` or `_initial_form_count` attributes of `BaseFormSet`. Those attributes are now public methods.

## Fixed the `join` filter’s escaping behavior

The `join` filter no longer escapes the literal value that is passed in for the connector.

This is backwards incompatible for the special situation of the literal string containing one of the five special HTML characters. Thus, if you were writing `{{ foo|join: "&" }}`, you now have to write `{{ foo|join: "&amp;" }}`.

The previous behavior was a bug and contrary to what was documented and expected.

## Permanent redirects and the `redirect_to()` generic view

Django 1.1 adds a `permanent` argument to the `django.views.generic.simple.redirect_to()` view. This is technically backwards-incompatible if you were using the `redirect_to` view with a format-string key called `'permanent'`, which is highly unlikely.

## Features deprecated in 1.1

One feature has been marked as deprecated in Django 1.1:

- You should no longer use `AdminSite.root()` to register that admin views. That is, if your URLconf contains the line:

```
(r'^admin/(.*)', admin.site.root),
```

You should change it to read:

```
(r'^admin/', include(admin.site.urls)),
```

You should begin to remove use of this feature from your code immediately.

`AdminSite.root()` will raise a `PendingDeprecationWarning` if used in Django 1.1. This warning is hidden by default. In Django 1.2, this warning will be upgraded to a `DeprecationWarning`, which will be displayed loudly. Django 1.3 will remove `AdminSite.root()` entirely.

For more details on our deprecation policies and strategy, see [Django's release process](#).

## What's new in Django 1.1

Quite a bit: since Django 1.0, we've made 1,290 code commits, fixed 1,206 bugs, and added roughly 10,000 lines of documentation.

The major new features in Django 1.1 are:

### ORM improvements

Two major enhancements have been added to Django's object-relational mapper (ORM): aggregate support, and query expressions.

### Aggregate support

It's now possible to run SQL aggregate queries (i.e. `COUNT()`, `MAX()`, `MIN()`, etc.) from within Django's ORM. You can choose to either return the results of the aggregate directly, or else annotate the objects in a `QuerySet` with the results of the aggregate query.

This feature is available as new `aggregate()` and `annotate()` methods, and is covered in detail in [the ORM aggregation documentation](#).

## Query expressions

Queries can now refer to another field on the query and can traverse relationships to refer to fields on related models. This is implemented in the new *F* object; for full details, including examples, consult the *F expressions documentation*.

## Model improvements

A number of features have been added to Django's model layer:

### “Unmanaged” models

You can now control whether or not Django manages the life-cycle of the database tables for a model using the *managed* model option. This defaults to `True`, meaning that Django will create the appropriate database tables in `syncdb` and remove them as part of the `reset` command. That is, Django *manages* the database table's lifecycle.

If you set this to `False`, however, no database table creating or deletion will be automatically performed for this model. This is useful if the model represents an existing table or a database view that has been created by some other means.

For more details, see the documentation for the *managed* option.

### Proxy models

You can now create *proxy models*: subclasses of existing models that only add Python-level (rather than database-level) behavior and aren't represented by a new table. That is, the new model is a *proxy* for some underlying model, which stores all the real data.

All the details can be found in the *proxy models documentation*. This feature is similar on the surface to unmanaged models, so the documentation has an explanation of *how proxy models differ from unmanaged models*.

### Deferred fields

In some complex situations, your models might contain fields which could contain a lot of data (for example, large text fields), or require expensive processing to convert them to Python objects. If you know you don't need those particular fields, you can now tell Django not to retrieve them from the database.

You'll do this with the new queryset methods *defer()* and *only()*.

### Testing improvements

A few notable improvements have been made to the *testing framework*.

### Test performance improvements

Tests written using Django's *testing framework* now run dramatically faster (as much as 10 times faster in many cases).

This was accomplished through the introduction of transaction-based tests: when using *django.test.TestCase*, your tests will now be run in a transaction which is rolled back when finished, instead of by flushing and re-populating

the database. This results in an immense speedup for most types of unit tests. See the documentation for *TestCase* and *TransactionTestCase* for a full description, and some important notes on database support.

## Test client improvements

A couple of small – but highly useful – improvements have been made to the test client:

- The test *Client* now can automatically follow redirects with the `follow` argument to *Client.get()* and *Client.post()*. This makes testing views that issue redirects simpler.
- It's now easier to get at the template context in the response returned the test client: you'll simply access the context as `request.context[key]`. The old way, which treats `request.context` as a list of contexts, one for each rendered template in the inheritance chain, is still available if you need it.

## New admin features

Django 1.1 adds a couple of nifty new features to Django's admin interface:

### Editable fields on the change list

You can now make fields editable on the admin list views via the new *list\_editable* admin option. These fields will show up as form widgets on the list pages, and can be edited and saved in bulk.

### Admin “actions”

You can now define *admin actions* that can perform some action to a group of models in bulk. Users will be able to select objects on the change list page and then apply these bulk actions to all selected objects.

Django ships with one pre-defined admin action to delete a group of objects in one fell swoop.

### Conditional view processing

Django now has much better support for *conditional view processing* using the standard ETag and Last-Modified HTTP headers. This means you can now easily short-circuit view processing by testing less-expensive conditions. For many views this can lead to a serious improvement in speed and reduction in bandwidth.

## URL namespaces

Django 1.1 improves *named URL patterns* with the introduction of URL “namespaces.”

In short, this feature allows the same group of URLs, from the same application, to be included in a Django URLConf multiple times, with varying (and potentially nested) named prefixes which will be used when performing reverse resolution. In other words, reusable applications like Django's admin interface may be registered multiple times without URL conflicts.

For full details, see *the documentation on defining URL namespaces*.

## GeoDjango

In Django 1.1, `GeoDjango` (i.e. `django.contrib.gis`) has several new features:

- Support for `Spatialite` – a spatial database for `SQLite` – as a spatial backend.
- Geographic aggregates (`Collect`, `Extent`, `MakeLine`, `Union`) and `F` expressions.
- New `GeoQuerySet` methods: `collect`, `geojson`, and `snap_to_grid`.
- A new list interface methods for `GEOSGeometry` objects.

For more details, see the `GeoDjango` documentation.

## Other improvements

Other new features and changes introduced since Django 1.0 include:

- The *CSRF protection middleware* has been split into two classes – `CsrfViewMiddleware` checks incoming requests, and `CsrfResponseMiddleware` processes outgoing responses. The combined `CsrfMiddleware` class (which does both) remains for backwards-compatibility, but using the split classes is now recommended in order to allow fine-grained control of when and where the CSRF processing takes place.
- `reverse()` and code which uses it (e.g., the `{% url %}` template tag) now works with URLs in Django’s administrative site, provided that the admin URLs are set up via `include(admin.site.urls)` (sending admin requests to the `admin.site.root` view still works, but URLs in the admin will not be “reversible” when configured this way).
- The `include()` function in Django URLconf modules can now accept sequences of URL patterns (generated by `patterns()`) in addition to module names.
- Instances of Django forms (see *the forms overview*) now have two additional methods, `hidden_fields()` and `visible_fields()`, which return the list of hidden – i.e., `<input type="hidden">` – and visible fields on the form, respectively.
- The `redirect_to` generic view now accepts an additional keyword argument `permanent`. If `permanent` is `True`, the view will emit an HTTP permanent redirect (status code 301). If `False`, the view will emit an HTTP temporary redirect (status code 302).
- A new database lookup type – `week_day` – has been added for `DateField` and `DateTimeField`. This type of lookup accepts a number between 1 (Sunday) and 7 (Saturday), and returns objects where the field value matches that day of the week. See *the full list of lookup types* for details.
- The `{% for %}` tag in Django’s template language now accepts an optional `{% empty %}` clause, to be displayed when `{% for %}` is asked to loop over an empty sequence. See *the list of built-in template tags* for examples of this.
- The *dumpdata* management command now accepts individual model names as arguments, allowing you to export the data just from particular models.
- There’s a new *safeseq* template filter which works just like *safe* for lists, marking each item in the list as safe.
- *Cache backends* now support `incr()` and `decr()` commands to increment and decrement the value of a cache key. On cache backends that support atomic increment/decrement – most notably, the `memcached` backend – these operations will be atomic, and quite fast.
- Django now can *easily delegate authentication to the Web server* via a new authentication backend that supports the standard `REMOTE_USER` environment variable used for this purpose.

- There’s a new `django.shortcuts.redirect()` function that makes it easier to issue redirects given an object, a view name, or a URL.
- The `postgresql_psycopg2` backend now supports *native PostgreSQL autocommit*. This is an advanced, PostgreSQL-specific feature, that can make certain read-heavy applications a good deal faster.

## What’s next?

We’ll take a short break, and then work on Django 1.2 will begin – no rest for the weary! If you’d like to help, discussion of Django development, including progress toward the 1.2 release, takes place daily on the *django-developers* mailing list and in the `#django-dev` IRC channel on `irc.freenode.net`. Feel free to join the discussions!

Django’s online documentation also includes pointers on how to contribute to Django:

- *How to contribute to Django*

Contributions on any level – developing code, writing documentation or simply triaging tickets and helping to test proposed bugfixes – are always welcome and appreciated.

And that’s the way it is.

## 9.1.11 1.0 release

### Django 1.0.2 release notes

Welcome to Django 1.0.2!

This is the second “bugfix” release in the Django 1.0 series, improving the stability and performance of the Django 1.0 codebase. As such, Django 1.0.2 contains no new features (and, pursuant to *our compatibility policy*, maintains backwards compatibility with Django 1.0.0), but does contain a number of fixes and other improvements. Django 1.0.2 is a recommended upgrade for any development or deployment currently using or targeting Django 1.0.

### Fixes and improvements in Django 1.0.2

The primary reason behind this release is to remedy an issue in the recently-released Django 1.0.1; the packaging scripts used for Django 1.0.1 omitted some directories from the final release package, including one directory required by `django.contrib.gis` and part of Django’s unit-test suite.

Django 1.0.2 contains updated packaging scripts, and the release package contains the directories omitted from Django 1.0.1. As such, this release contains all of the fixes and improvements from Django 1.0.1; see *the Django 1.0.1 release notes* for details.

Additionally, in the period since Django 1.0.1 was released:

- Updated Hebrew and Danish translations have been added.
- The default `__repr__` method of Django models has been made more robust in the face of bad Unicode data coming from the `__unicode__` method; rather than raise an exception in such cases, `repr()` will now contain the string “[Bad Unicode data]” in place of the invalid Unicode.
- A bug involving the interaction of Django’s `SafeUnicode` class and the MySQL adapter has been resolved; `SafeUnicode` instances (generated, for example, by template rendering) can now be assigned to model attributes and saved to MySQL without requiring an explicit intermediate cast to `unicode`.
- A bug affecting filtering on a nullable `DateField` in SQLite has been resolved.
- Several updates and improvements have been made to Django’s documentation.

## Django 1.0.1 release notes

Welcome to Django 1.0.1!

This is the first “bugfix” release in the Django 1.0 series, improving the stability and performance of the Django 1.0 codebase. As such, Django 1.0.1 contains no new features (and, pursuant to *our compatibility policy*, maintains backwards compatibility with Django 1.0), but does contain a number of fixes and other improvements. Django 1.0.1 is a recommended upgrade for any development or deployment currently using or targeting Django 1.0.

### Fixes and improvements in Django 1.0.1

Django 1.0.1 contains over two hundred fixes to the original Django 1.0 codebase; full details of every fix are available in [the history of the 1.0.X branch](#), but here are some of the highlights:

- Several fixes in `django.contrib.comments`, pertaining to RSS feeds of comments, default ordering of comments and the XHTML and internationalization of the default templates for comments.
- Multiple fixes for Django’s support of Oracle databases, including pagination support for GIS QuerySets, more efficient slicing of results and improved introspection of existing databases.
- Several fixes for query support in the Django object-relational mapper, including repeated setting and resetting of ordering and fixes for working with INSERT-only queries.
- Multiple fixes for inline forms in formsets.
- Multiple fixes for `unique` and `unique_together` model constraints in automatically-generated forms.
- Fixed support for custom callable `upload_to` declarations when handling file uploads through automatically-generated forms.
- Fixed support for sorting an admin change list based on a callable attributes in `list_display`.
- A fix to the application of autoescaping for literal strings passed to the `join` template filter. Previously, literal strings passed to `join` were automatically escaped, contrary to *the documented behavior for autoescaping and literal strings*. Literal strings passed to `join` are no longer automatically escaped, meaning you must now manually escape them; this is an incompatibility if you were relying on this bug, but not if you were relying on escaping behaving as documented.
- Improved and expanded translation files for many of the languages Django supports by default.
- And as always, a large number of improvements to Django’s documentation, including both corrections to existing documents and expanded and new documentation.

## Django 1.0 release notes

Welcome to Django 1.0!

We’ve been looking forward to this moment for over three years, and it’s finally here. Django 1.0 represents the largest milestone in Django’s development to date: a Web framework that a group of perfectionists can truly be proud of.

Django 1.0 represents over three years of community development as an Open Source project. Django’s received contributions from hundreds of developers, been translated into fifty languages, and today is used by developers on every continent and in every kind of job.

An interesting historical note: when Django was first released in July 2005, the initial released version of Django came from an internal repository at revision number 8825. Django 1.0 represents revision 8961 of our public repository. It seems fitting that our 1.0 release comes at the moment where community contributions overtake those made privately.

## Stability and forwards-compatibility

The release of Django 1.0 comes with a promise of API stability and forwards-compatibility. In a nutshell, this means that code you develop against Django 1.0 will continue to work against 1.1 unchanged, and you should need to make only minor changes for any 1.X release.

See the *API stability guide* for full details.

## Backwards-incompatible changes

Django 1.0 has a number of backwards-incompatible changes from Django 0.96. If you have apps written against Django 0.96 that you need to port, see our detailed porting guide:

## Porting your apps from Django 0.96 to 1.0

Django 1.0 breaks compatibility with 0.96 in some areas.

This guide will help you port 0.96 projects and apps to 1.0. The first part of this document includes the common changes needed to run with 1.0. If after going through the first part your code still breaks, check the section *Less-common Changes* for a list of a bunch of less-common compatibility issues.

### See also:

The *1.0 release notes*. That document explains the new features in 1.0 more deeply; the porting guide is more concerned with helping you quickly update your code.

## Common changes

This section describes the changes between 0.96 and 1.0 that most users will need to make.

### Use Unicode

Change string literals ('foo') into Unicode literals (u'foo'). Django now uses Unicode strings throughout. In most places, raw strings will continue to work, but updating to use Unicode literals will prevent some obscure problems.

See *Unicode data* for full details.

### Models

Common changes to your models file:

#### Rename `maxlength` to `max_length`

Rename your `maxlength` argument to `max_length` (this was changed to be consistent with form fields):

#### Replace `__str__` with `__unicode__`

Replace your model's `__str__` function with a `__unicode__` method, and make sure you *use Unicode* (u'foo') in that method.

## Remove `prepopulated_from`

Remove the `prepopulated_from` argument on model fields. It's no longer valid and has been moved to the `ModelAdmin` class in `admin.py`. See *the admin*, below, for more details about changes to the admin.

## Remove `core`

Remove the `core` argument from your model fields. It is no longer necessary, since the equivalent functionality (part of *inline editing*) is handled differently by the admin interface now. You don't have to worry about inline editing until you get to *the admin* section, below. For now, remove all references to `core`.

## Replace `class Admin:` with `admin.py`

Remove all your inner `class Admin` declarations from your models. They won't break anything if you leave them, but they also won't do anything. To register apps with the admin you'll move those declarations to an `admin.py` file; see *the admin* below for more details.

### See also:

A contributor to [djangosnippets](#) has written a script that'll scan your `models.py` and generate a corresponding `admin.py`.

## Example

Below is an example `models.py` file with all the changes you'll need to make:

Old (0.96) `models.py`:

```
class Author(models.Model):
    first_name = models.CharField(maxlength=30)
    last_name = models.CharField(maxlength=30)
    slug = models.CharField(maxlength=60, prepopulate_from=('first_name', 'last_name
↵'))

    class Admin:
        list_display = ['first_name', 'last_name']

    def __str__(self):
        return '%s %s' % (self.first_name, self.last_name)
```

New (1.0) `models.py`:

```
class Author(models.Model):
    first_name = models.CharField(max_length=30)
    last_name = models.CharField(max_length=30)
    slug = models.CharField(max_length=60)

    def __unicode__(self):
        return u'%s %s' % (self.first_name, self.last_name)
```

New (1.0) `admin.py`:

```
from django.contrib import admin
from models import Author
```

```
class AuthorAdmin(admin.ModelAdmin):
    list_display = ['first_name', 'last_name']
    prepopulated_fields = {
        'slug': ('first_name', 'last_name')
    }

admin.site.register(Author, AuthorAdmin)
```

## The Admin

One of the biggest changes in 1.0 is the new admin. The Django administrative interface (`django.contrib.admin`) has been completely refactored; admin definitions are now completely decoupled from model definitions, the framework has been rewritten to use Django's new form-handling library and redesigned with extensibility and customization in mind.

Practically, this means you'll need to rewrite all of your `class Admin` declarations. You've already seen in *models* above how to replace your `class Admin` with a `admin.site.register()` call in an `admin.py` file. Below are some more details on how to rewrite that Admin declaration into the new syntax.

### Use new inline syntax

The new `edit_inline` options have all been moved to `admin.py`. Here's an example:

Old (0.96):

```
class Parent(models.Model):
    ...

class Child(models.Model):
    parent = models.ForeignKey(Parent, edit_inline=models.STACKED, num_in_admin=3)
```

New (1.0):

```
class ChildInline(admin.StackedInline):
    model = Child
    extra = 3

class ParentAdmin(admin.ModelAdmin):
    model = Parent
    inlines = [ChildInline]

admin.site.register(Parent, ParentAdmin)
```

See *InlineModelAdmin objects* for more details.

### Simplify fields, or use fieldsets

The old `fields` syntax was quite confusing, and has been simplified. The old syntax still works, but you'll need to use `fieldsets` instead.

Old (0.96):

```
class ModelOne(models.Model):
    ...

    class Admin:
        fields = (
            (None, {'fields': ('foo', 'bar')}),
        )

class ModelTwo(models.Model):
    ...

    class Admin:
        fields = (
            ('group1', {'fields': ('foo', 'bar'), 'classes': 'collapse'}),
            ('group2', {'fields': ('spam', 'eggs'), 'classes': 'collapse wide'}),
        )
```

New (1.0):

```
class ModelOneAdmin(admin.ModelAdmin):
    fields = ('foo', 'bar')

class ModelTwoAdmin(admin.ModelAdmin):
    fieldsets = (
        ('group1', {'fields': ('foo', 'bar'), 'classes': 'collapse'}),
        ('group2', {'fields': ('spam', 'eggs'), 'classes': 'collapse wide'}),
    )
```

See also:

- More detailed information about the changes and the reasons behind them can be found on the [NewformsAdminBranch](#) wiki page
- The new admin comes with a ton of new features; you can read about them in the [admin documentation](#).

## URLs

### Update your root `urls.py`

If you're using the admin site, you need to update your root `urls.py`.

Old (0.96) `urls.py`:

```
from django.conf.urls.defaults import *

urlpatterns = patterns('',
    (r'^admin/', include('django.contrib.admin.urls')),

    # ... the rest of your URLs here ...
)
```

New (1.0) `urls.py`:

```
from django.conf.urls.defaults import *

# The next two lines enable the admin and load each admin.py file:
from django.contrib import admin
```

```
admin.autodiscover()

urlpatterns = patterns('',
    (r'^admin/(.*)', admin.site.root),

    # ... the rest of your URLs here ...
)
```

## Views

### Use `django.forms` instead of `newforms`

Replace `django.newforms` with `django.forms` – Django 1.0 renamed the `newforms` module (introduced in 0.96) to plain old `forms`. The `oldforms` module was also removed.

If you're already using the `newforms` library, and you used our recommended `import` statement syntax, all you have to do is change your import statements.

Old:

```
from django import newforms as forms
```

New:

```
from django import forms
```

If you're using the old `forms` system (formerly known as `django.forms` and `django.oldforms`), you'll have to rewrite your forms. A good place to start is the [forms documentation](#)

### Handle uploaded files using the new API

Replace use of uploaded files – that is, entries in `request.FILES` – as simple dictionaries with the new [UploadedFile](#). The old dictionary syntax no longer works.

Thus, in a view like:

```
def my_view(request):
    f = request.FILES['file_field_name']
    ...
```

...you'd need to make the following changes:

Old (0.96)	New (1.0)
<code>f['content']</code>	<code>f.read()</code>
<code>f['filename']</code>	<code>f.name</code>
<code>f['content-type']</code>	<code>f.content_type</code>

### Work with file fields using the new API

The internal implementation of `django.db.models.FileField` have changed. A visible result of this is that the way you access special attributes (URL, filename, image size, etc.) of these model fields has changed. You will need to make the following changes, assuming your model's `FileField` is called `myfile`:

Old (0.96)	New (1.0)
<code>myfile.get_content_filename()</code>	<code>myfile.content.path</code>
<code>myfile.get_content_url()</code>	<code>myfile.content.url</code>
<code>myfile.get_content_size()</code>	<code>myfile.content.size</code>
<code>myfile.save_content_file()</code>	<code>myfile.content.save()</code>
<code>myfile.get_content_width()</code>	<code>myfile.content.width</code>
<code>myfile.get_content_height()</code>	<code>myfile.content.height</code>

Note that the `width` and `height` attributes only make sense for *ImageField* fields. More details can be found in the *model API* documentation.

## Use `Paginator` instead of `ObjectPaginator`

The `ObjectPaginator` in 0.96 has been removed and replaced with an improved version, `django.core.paginator.Paginator`.

## Templates

### Learn to love autoescaping

By default, the template system now automatically HTML-escapes the output of every variable. To learn more, see *Automatic HTML escaping*.

To disable auto-escaping for an individual variable, use the `safe` filter:

```
This will be escaped: {{ data }}
This will not be escaped: {{ data|safe }}
```

To disable auto-escaping for an entire template, wrap the template (or just a particular section of the template) in the `autoescape` tag:

```
{% autoescape off %}
... unescaped template content here ...
{% endautoescape %}
```

### Less-common changes

The following changes are smaller, more localized changes. They should only affect more advanced users, but it's probably worth reading through the list and checking your code for these things.

## Signals

- Add `**kwargs` to any registered signal handlers.
- Connect, disconnect, and send signals via methods on the *Signal* object instead of through module methods in `django.dispatch.dispatcher`.
- Remove any use of the `Anonymous` and `Any` sender options; they no longer exist. You can still receive signals sent by any sender by using `sender=None`.
- Make any custom signals you've declared into instances of `django.dispatch.Signal` instead of anonymous objects.

Here's quick summary of the code changes you'll need to make:

Old (0.96)	New (1.0)
<code>def callback(sender)</code>	<code>def callback(sender, **kwargs)</code>
<code>sig = object()</code>	<code>sig = django.dispatch.Signal()</code>
<code>dispatcher.connect(callback, sig)</code>	<code>sig.connect(callback)</code>
<code>dispatcher.send(sig, sender)</code>	<code>sig.send(sender)</code>
<code>dispatcher.connect(callback, sig, sender=Any)</code>	<code>sig.connect(callback, sender=None)</code>

## Comments

If you were using Django 0.96's `django.contrib.comments` app, you'll need to upgrade to the new comments app introduced in 1.0. See the upgrade guide for details.

## Template tags

### spaceless tag

The spaceless template tag now removes *all* spaces between HTML tags, instead of preserving a single space.

## Local flavors

### U.S. local flavor

`django.contrib.localflavor.usa` has been renamed to `django.contrib.localflavor.us`. This change was made to match the naming scheme of other local flavors. To migrate your code, all you need to do is change the imports.

## Sessions

### Getting a new session key

`SessionBase.get_new_session_key()` has been renamed to `_get_new_session_key()`. `get_new_session_object()` no longer exists.

## Fixtures

### Loading a row no longer calls `save()`

Previously, loading a row automatically ran the model's `save()` method. This is no longer the case, so any fields (for example: timestamps) that were auto-populated by a `save()` now need explicit values in any fixture.

## Settings

### Better exceptions

The old `EnvironmentError` has split into an `ImportError` when Django fails to find the settings module and a `RuntimeError` when you try to reconfigure settings after having already used them.

### LOGIN\_URL has moved

The `LOGIN_URL` constant moved from `django.contrib.auth` into the `settings` module. Instead of using `from django.contrib.auth import LOGIN_URL` refer to `settings.LOGIN_URL`.

### APPEND\_SLASH behavior has been updated

In 0.96, if a URL didn't end in a slash or have a period in the final component of its path, and `APPEND_SLASH` was `True`, Django would redirect to the same URL, but with a slash appended to the end. Now, Django checks to see whether the pattern without the trailing slash would be matched by something in your URL patterns. If so, no redirection takes place, because it is assumed you deliberately wanted to catch that pattern.

For most people, this won't require any changes. Some people, though, have URL patterns that look like this:

```
r'/some_prefix/(.*)$'
```

Previously, those patterns would have been redirected to have a trailing slash. If you always want a slash on such URLs, rewrite the pattern as:

```
r'/some_prefix/(.*)/$'
```

### Smaller model changes

#### Different exception from `get ()`

Managers now return a `MultipleObjectsReturned` exception instead of `AssertionError`:

Old (0.96):

```
try:
    Model.objects.get(...)
except AssertionError:
    handle_the_error()
```

New (1.0):

```
try:
    Model.objects.get(...)
except Model.MultipleObjectsReturned:
    handle_the_error()
```

## LazyDate has been fired

The `LazyDate` helper class no longer exists.

Default field values and query arguments can both be callable objects, so instances of `LazyDate` can be replaced with a reference to `datetime.datetime.now`:

Old (0.96):

```
class Article(models.Model):
    title = models.CharField(maxlength=100)
    published = models.DateField(default=LazyDate())
```

New (1.0):

```
import datetime

class Article(models.Model):
    title = models.CharField(max_length=100)
    published = models.DateField(default=datetime.datetime.now)
```

## DecimalField is new, and FloatField is now a proper float

Old (0.96):

```
class MyModel(models.Model):
    field_name = models.FloatField(max_digits=10, decimal_places=3)
    ...
```

New (1.0):

```
class MyModel(models.Model):
    field_name = models.DecimalField(max_digits=10, decimal_places=3)
    ...
```

If you forget to make this change, you will see errors about `FloatField` not taking a `max_digits` attribute in `__init__`, because the new `FloatField` takes no precision-related arguments.

If you're using MySQL or PostgreSQL, no further changes are needed. The database column types for `DecimalField` are the same as for the old `FloatField`.

If you're using SQLite, you need to force the database to view the appropriate columns as decimal types, rather than floats. To do this, you'll need to reload your data. Do this after you have made the change to using `DecimalField` in your code and updated the Django code.

### Warning: Back up your database first!

For SQLite, this means making a copy of the single file that stores the database (the name of that file is the `DATABASE_NAME` in your settings.py file).

To upgrade each application to use a `DecimalField`, you can do the following, replacing `<app>` in the code below with each app's name:

```
$ ./manage.py dumpdata --format=xml <app> > data-dump.xml
$ ./manage.py reset <app>
$ ./manage.py loaddata data-dump.xml
```

Notes:

1. It's important that you remember to use XML format in the first step of this process. We are exploiting a feature of the XML data dumps that makes porting floats to decimals with SQLite possible.
2. In the second step you will be asked to confirm that you are prepared to lose the data for the application(s) in question. Say yes; we'll restore this data in the third step, of course.
3. `DecimalField` is not used in any of the apps shipped with Django prior to this change being made, so you do not need to worry about performing this procedure for any of the standard Django models.

If something goes wrong in the above process, just copy your backed up database file over the original file and start again.

## Internationalization

### `django.views.i18n.set_language()` now requires a POST request

Previously, a GET request was used. The old behavior meant that state (the locale used to display the site) could be changed by a GET request, which is against the HTTP specification's recommendations. Code calling this view must ensure that a POST request is now made, instead of a GET. This means you can no longer use a link to access the view, but must use a form submission of some kind (e.g. a button).

### `_()` is no longer in builtins

`_()` (the callable object whose name is a single underscore) is no longer monkeypatched into builtins – that is, it's no longer available magically in every module.

If you were previously relying on `_()` always being present, you should now explicitly import `ugettext` or `ugettext_lazy`, if appropriate, and alias it to `_` yourself:

```
from django.utils.translation import ugettext as _
```

## HTTP request/response objects

### Dictionary access to `HttpRequest`

`HttpRequest` objects no longer directly support dictionary-style access; previously, both GET and POST data were directly available on the `HttpRequest` object (e.g., you could check for a piece of form data by using `if 'some_form_key' in request` or by reading `request['some_form_key']`). This is no longer supported; if you need access to the combined GET and POST data, use `request.REQUEST` instead.

It is strongly suggested, however, that you always explicitly look in the appropriate dictionary for the type of request you expect to receive (`request.GET` or `request.POST`); relying on the combined `request.REQUEST` dictionary can mask the origin of incoming data.

### Accessing `HttpResponse` headers

`django.http.HttpResponse.headers` has been renamed to `_headers` and `HttpResponse` now supports containment checking directly. So use `if header in response`: instead of `if header in response.headers`:

## Generic relations

### Generic relations have been moved out of core

The generic relation classes – `GenericForeignKey` and `GenericRelation` – have moved into the `django.contrib.contenttypes` module.

## Testing

### `django.test.Client.login()` has changed

Old (0.96):

```
from django.test import Client
c = Client()
c.login('/path/to/login', 'myuser', 'mypassword')
```

New (1.0):

```
# ... same as above, but then:
c.login(username='myuser', password='mypassword')
```

## Management commands

### Running management commands from your code

`django.core.management` has been greatly refactored.

Calls to management services in your code now need to use `call_command`. For example, if you have some test code that calls `flush` and `load_data`:

```
from django.core import management
management.flush(verbosity=0, interactive=False)
management.load_data(['test_data'], verbosity=0)
```

...you'll need to change this code to read:

```
from django.core import management
management.call_command('flush', verbosity=0, interactive=False)
management.call_command('loaddata', 'test_data', verbosity=0)
```

### Subcommands must now precede options

`django-admin.py` and `manage.py` now require subcommands to precede options. So:

```
$ django-admin.py --settings=foo.bar runserver
```

...no longer works and should be changed to:

```
$ django-admin.py runserver --settings=foo.bar
```

## Syndication

### Feed.\_\_init\_\_ has changed

The `__init__()` method of the syndication framework's `Feed` class now takes an `HttpRequest` object as its second parameter, instead of the feed's URL. This allows the syndication framework to work without requiring the sites framework. This only affects code that subclasses `Feed` and overrides the `__init__()` method, and code that calls `Feed.__init__()` directly.

## Data structures

### SortedDictFromList is gone

`django.newforms.forms.SortedDictFromList` was removed. `django.utils.datastructures.SortedDict` can now be instantiated with a sequence of tuples.

To update your code:

1. Use `django.utils.datastructures.SortedDict` wherever you were using `django.newforms.forms.SortedDictFromList`.
2. Because `django.utils.datastructures.SortedDict.copy` doesn't return a deepcopy as `SortedDictFromList.copy()` did, you will need to update your code if you were relying on a deep-copy. Do this by using `copy.deepcopy` directly.

## Database backend functions

### Database backend functions have been renamed

Almost *all* of the database backend-level functions have been renamed and/or relocated. None of these were documented, but you'll need to change your code if you're using any of these functions, all of which are in `django.db`:

Old (0.96)	New (1.0)
<code>backend.get_autoinc_sql</code>	<code>connection.ops.autoinc_sql</code>
<code>backend.get_date_extract_sql</code>	<code>connection.ops.date_extract_sql</code>
<code>backend.get_date_trunc_sql</code>	<code>connection.ops.date_trunc_sql</code>
<code>backend.get_datetime_cast_sql</code>	<code>connection.ops.datetime_cast_sql</code>
<code>backend.get_deferrable_sql</code>	<code>connection.ops.deferrable_sql</code>
<code>backend.get_drop_foreignkey_sql</code>	<code>connection.ops.drop_foreignkey_sql</code>
<code>backend.get_fulltext_search_sql</code>	<code>connection.ops.fulltext_search_sql</code>
<code>backend.get_last_insert_id</code>	<code>connection.ops.last_insert_id</code>
<code>backend.get_limit_offset_sql</code>	<code>connection.ops.limit_offset_sql</code>
<code>backend.get_max_name_length</code>	<code>connection.ops.max_name_length</code>
<code>backend.get_pk_default_value</code>	<code>connection.ops.pk_default_value</code>
<code>backend.get_random_function_sql</code>	<code>connection.ops.random_function_sql</code>
<code>backend.get_sql_flush</code>	<code>connection.ops.sql_flush</code>
<code>backend.get_sql_sequence_reset</code>	<code>connection.ops.sequence_reset_sql</code>
<code>backend.get_start_transaction_sql</code>	<code>connection.ops.start_transaction_sql</code>
<code>backend.get_tablespace_sql</code>	<code>connection.ops.tablespace_sql</code>
<code>backend.quote_name</code>	<code>connection.ops.quote_name</code>
Continued on next page	

Table 9.1 – continued from previous page

Old (0.96)	New (1.0)
<code>backend.get_query_set_class</code>	<code>connection.ops.query_set_class</code>
<code>backend.get_field_cast_sql</code>	<code>connection.ops.field_cast_sql</code>
<code>backend.get_drop_sequence</code>	<code>connection.ops.drop_sequence_sql</code>
<code>backend.OPERATOR_MAPPING</code>	<code>connection.operators</code>
<code>backend.allows_group_by_ordinal</code>	<code>connection.features.allows_group_by_ordinal</code>
<code>backend.allows_unique_and_pk</code>	<code>connection.features.allows_unique_and_pk</code>
<code>backend.autoindexes_primary_keys</code>	<code>connection.features.autoindexes_primary_keys</code>
<code>backend.needs_datetime_string_cast</code>	<code>connection.features.needs_datetime_string_cast</code>
<code>backend.needs_upper_for_iops</code>	<code>connection.features.needs_upper_for_iops</code>
<code>backend.supports_constraints</code>	<code>connection.features.supports_constraints</code>
<code>backend.supports_tablespaces</code>	<code>connection.features.supports_tablespaces</code>
<code>backend.uses_case_insensitive_names</code>	<code>connection.features.uses_case_insensitive_names</code>
<code>backend.uses_custom_queryset</code>	<code>connection.features.uses_custom_queryset</code>

A complete list of backwards-incompatible changes can be found at <https://code.djangoproject.com/wiki/BackwardsIncompatibleChanges>.

## What's new in Django 1.0

*A lot!*

Since Django 0.96, we've made over 4,000 code commits, fixed more than 2,000 bugs, and edited, added, or removed around 350,000 lines of code. We've also added 40,000 lines of new documentation, and greatly improved what was already there.

In fact, new documentation is one of our favorite features of Django 1.0, so we might as well start there. First, there's a new documentation site:

- <https://docs.djangoproject.com/>

The documentation has been greatly improved, cleaned up, and generally made awesome. There's now dedicated search, indexes, and more.

We can't possibly document everything that's new in 1.0, but the documentation will be your definitive guide. Anywhere you see something like:

This feature is new in Django 1.0

You'll know that you're looking at something new or changed.

The other major highlights of Django 1.0 are:

### Re-factored admin application

The Django administrative interface (`django.contrib.admin`) has been completely refactored; admin definitions are now completely decoupled from model definitions (no more `class Admin` declaration in models!), rewritten to use Django's new form-handling library (introduced in the 0.96 release as `django.newforms`, and now available as simply `django.forms`) and redesigned with extensibility and customization in mind. Full documentation for the admin application is available online in the official Django documentation:

See the *admin reference* for details

## Improved Unicode handling

Django’s internals have been refactored to use Unicode throughout; this drastically simplifies the task of dealing with non-Western-European content and data in Django. Additionally, utility functions have been provided to ease interoperability with third-party libraries and systems which may or may not handle Unicode gracefully. Details are available in Django’s Unicode-handling documentation.

See *Unicode data*.

## An improved ORM

Django’s object-relational mapper – the component which provides the mapping between Django model classes and your database, and which mediates your database queries – has been dramatically improved by a massive refactoring. For most users of Django this is backwards-compatible; the public-facing API for database querying underwent a few minor changes, but most of the updates took place in the ORM’s internals. A guide to the changes, including backwards-incompatible modifications and mentions of new features opened up by this refactoring, is [available on the Django wiki](#).

## Automatic escaping of template variables

To provide improved security against cross-site scripting (XSS) vulnerabilities, Django’s template system now automatically escapes the output of variables. This behavior is configurable, and allows both variables and larger template constructs to be marked as safe (requiring no escaping) or unsafe (requiring escaping). A full guide to this feature is in the documentation for the *autoescape* tag.

## `django.contrib.gis` (GeoDjango)

A project over a year in the making, this adds world-class GIS (Geographic Information Systems) support to Django, in the form of a `contrib` application. Its documentation is currently being maintained externally, and will be merged into the main Django documentation shortly. Huge thanks go to Justin Bronn, Jeremy Dunck, Brett Hoerner and Travis Pinney for their efforts in creating and completing this feature.

See <http://geodjango.org/> for details.

## Pluggable file storage

Django’s built-in `FileField` and `ImageField` now can take advantage of pluggable file-storage backends, allowing extensive customization of where and how uploaded files get stored by Django. For details, see *the files documentation*; big thanks go to Marty Alchin for putting in the hard work to get this completed.

## Jython compatibility

Thanks to a lot of work from Leo Soto during a Google Summer of Code project, Django’s codebase has been refactored to remove incompatibilities with *Jython*, an implementation of Python written in Java, which runs Python code on the Java Virtual Machine. Django is now compatible with the forthcoming Jython 2.5 release.

See *Running Django on Jython*.

## Generic relations in forms and admin

Classes are now included in `django.contrib.contenttypes` which can be used to support generic relations in both the admin interface and in end-user forms. See *the documentation for generic relations* for details.

### INSERT/UPDATE distinction

Although Django's default behavior of having a model's `save()` method automatically determine whether to perform an `INSERT` or an `UPDATE` at the SQL level is suitable for the majority of cases, there are occasional situations where forcing one or the other is useful. As a result, models can now support an additional parameter to `save()` which can force a specific operation.

See *Forcing an INSERT or UPDATE* for details.

### Split CacheMiddleware

Django's `CacheMiddleware` has been split into three classes: `CacheMiddleware` itself still exists and retains all of its previous functionality, but it is now built from two separate middleware classes which handle the two parts of caching (inserting into and reading from the cache) separately, offering additional flexibility for situations where combining these functions into a single middleware posed problems.

Full details, including updated notes on appropriate use, are in *the caching documentation*.

### Refactored `django.contrib.comments`

As part of a Google Summer of Code project, Thejaswi Puthraya carried out a major rewrite and refactoring of Django's bundled comment system, greatly increasing its flexibility and customizability.

### Removal of deprecated features

A number of features and methods which had previously been marked as deprecated, and which were scheduled for removal prior to the 1.0 release, are no longer present in Django. These include imports of the form library from `django.newforms` (now located simply at `django.forms`), the `form_for_model` and `form_for_instance` helper functions (which have been replaced by `ModelForm`) and a number of deprecated features which were replaced by the dispatcher, file-uploading and file-storage refactorings introduced in the Django 1.0 alpha releases.

### Known issues

We've done our best to make Django 1.0 as solid as possible, but unfortunately there are a couple of issues that we know about in the release.

### Multi-table model inheritance with `to_field`

If you're using *multiple table model inheritance*, be aware of this caveat: child models using a custom `parent_link` and `to_field` will cause database integrity errors. A set of models like the following are **not valid**:

```
class Parent(models.Model):
    name = models.CharField(max_length=10)
    other_value = models.IntegerField(unique=True)

class Child(Parent):
    father = models.OneToOneField(Parent, primary_key=True, to_field="other_value",
    ↪parent_link=True)
    value = models.IntegerField()
```

This bug will be fixed in the next release of Django.

## Caveats with support of certain databases

Django attempts to support as many features as possible on all database backends. However, not all database backends are alike, and in particular many of the supported database differ greatly from version to version. It's a good idea to checkout our *notes on supported database*:

- [MySQL notes](#)
- [SQLite notes](#)
- [Oracle notes](#)

## 9.1.12 Pre-1.0 releases

### Django version 0.96 release notes

Welcome to Django 0.96!

The primary goal for 0.96 is a cleanup and stabilization of the features introduced in 0.95. There have been a few small *backwards-incompatible changes* since 0.95, but the upgrade process should be fairly simple and should not require major changes to existing applications.

However, we're also releasing 0.96 now because we have a set of backwards-incompatible changes scheduled for the near future. Once completed, they will involve some code changes for application developers, so we recommend that you stick with Django 0.96 until the next official release; then you'll be able to upgrade in one step instead of needing to make incremental changes to keep up with the development version of Django.

### Backwards-incompatible changes

The following changes may require you to update your code when you switch from 0.95 to 0.96:

#### MySQLdb version requirement

Due to a bug in older versions of the MySQLdb Python module (which Django uses to connect to MySQL databases), Django's MySQL backend now requires version 1.2.1p2 or higher of MySQLdb, and will raise exceptions if you attempt to use an older version.

If you're currently unable to upgrade your copy of MySQLdb to meet this requirement, a separate, backwards-compatible backend, called "mysql\_old", has been added to Django. To use this backend, change the DATABASE\_ENGINE setting in your Django settings file from this:

```
DATABASE_ENGINE = "mysql"
```

to this:

```
DATABASE_ENGINE = "mysql_old"
```

However, we strongly encourage MySQL users to upgrade to a more recent version of MySQLdb as soon as possible. The “mysql\_old” backend is provided only to ease this transition, and is considered deprecated; aside from any necessary security fixes, it will not be actively maintained, and it will be removed in a future release of Django.

Also, note that some features, like the new `DATABASE_OPTIONS` setting (see the [databases documentation](#) for details), are only available on the “mysql” backend, and will not be made available for “mysql\_old”.

## Database constraint names changed

The format of the constraint names Django generates for foreign key references have changed slightly. These names are generally only used when it is not possible to put the reference directly on the affected column, so they are not always visible.

The effect of this change is that running `manage.py reset` and similar commands against an existing database may generate SQL with the new form of constraint name, while the database itself contains constraints named in the old form; this will cause the database server to raise an error message about modifying non-existent constraints.

If you need to work around this, there are two methods available:

1. Redirect the output of `manage.py` to a file, and edit the generated SQL to use the correct constraint names before executing it.
2. Examine the output of `manage.py sqlall` to see the new-style constraint names, and use that as a guide to rename existing constraints in your database.

## Name changes in `manage.py`

A few of the options to `manage.py` have changed with the addition of fixture support:

- There are new `dumpdata` and `loaddata` commands which, as you might expect, will dump and load data to/from the database. These commands can operate against any of Django’s supported serialization formats.
- The `sqlinitialdata` command has been renamed to `sqlcustom` to emphasize that `loaddata` should be used for data (and `sqlcustom` for other custom SQL – views, stored procedures, etc.).
- The vestigial `install` command has been removed. Use `syncdb`.

## Backslash escaping changed

The Django database API now escapes backslashes given as query parameters. If you have any database API code that matches backslashes, and it was working before (despite the lack of escaping), you’ll have to change your code to “unescape” the slashes one level.

For example, this used to work:

```
# Find text containing a single backslash
MyModel.objects.filter(text__contains='\\')
```

The above is now incorrect, and should be rewritten as:

```
# Find text containing a single backslash
MyModel.objects.filter(text__contains='\\')
```

## Removed ENABLE\_PSYCO setting

The `ENABLE_PSYCO` setting no longer exists. If your settings file includes `ENABLE_PSYCO` it will have no effect; to use `Psyco`, we recommend writing a middleware class to activate it.

## What's new in 0.96?

This revision represents over a thousand source commits and over four hundred bug fixes, so we can't possibly catalog all the changes. Here, we describe the most notable changes in this release.

## New forms library

`django.newforms` is Django's new form-handling library. It's a replacement for `django.forms`, the old form/manipulator/validation framework. Both APIs are available in 0.96, but over the next two releases we plan to switch completely to the new forms system, and deprecate and remove the old system.

There are three elements to this transition:

- We've copied the current `django.forms` to `django.oldforms`. This allows you to upgrade your code *now* rather than waiting for the backwards-incompatible change and rushing to fix your code after the fact. Just change your import statements like this:

```
from django import forms # 0.95-style
from django import oldforms as forms # 0.96-style
```

- The next official release of Django will move the current `django.newforms` to `django.forms`. This will be a backwards-incompatible change, and anyone still using the old version of `django.forms` at that time will need to change their import statements as described above.
- The next release after that will completely remove `django.oldforms`.

Although the `newforms` library will continue to evolve, it's ready for use for most common cases. We recommend that anyone new to form handling skip the old forms system and start with the new.

For more information about `django.newforms`, read the [newforms documentation](#).

## URLconf improvements

You can now use any callable as the callback in URLconfs (previously, only strings that referred to callables were allowed). This allows a much more natural use of URLconfs. For example, this URLconf:

```
from django.conf.urls.defaults import *

urlpatterns = patterns('',
    ('^myview/$', 'mysite.myapp.views.myview')
)
```

can now be rewritten as:

```
from django.conf.urls.defaults import *
from mysite.myapp.views import myview

urlpatterns = patterns('',
    ('^myview/$', myview)
)
```

One useful application of this can be seen when using decorators; this change allows you to apply decorators to views *in your URLconf*. Thus, you can make a generic view require login very easily:

```
from django.conf.urls.defaults import *
from django.contrib.auth.decorators import login_required
from django.views.generic.list_detail import object_list
from mysite.myapp.models import MyModel

info = {
    "queryset" : MyModel.objects.all(),
}

urlpatterns = patterns('',
    ('^myview/$', login_required(object_list), info)
)
```

Note that both syntaxes (strings and callables) are valid, and will continue to be valid for the foreseeable future.

## The test framework

Django now includes a test framework so you can start transmuting fear into boredom (with apologies to Kent Beck). You can write tests based on `doctest` or `unittest` and test your views with a simple test client.

There is also new support for “fixtures” – initial data, stored in any of the supported *serialization formats*, that will be loaded into your database at the start of your tests. This makes testing with real data much easier.

See *the testing documentation* for the full details.

## Improvements to the admin interface

A small change, but a very nice one: dedicated views for adding and updating users have been added to the admin interface, so you no longer need to worry about working with hashed passwords in the admin.

## Thanks

Since 0.95, a number of people have stepped forward and taken a major new role in Django’s development. We’d like to thank these people for all their hard work:

- Russell Keith-Magee and Malcolm Tredinnick for their major code contributions. This release wouldn’t have been possible without them.
- Our new release manager, James Bennett, for his work in getting out 0.95.1, 0.96, and (hopefully) future release.
- Our ticket managers Chris Beaven (aka SmileyChris), Simon Greenhill, Michael Radziej, and Gary Wilson. They agreed to take on the monumental task of wrangling our tickets into nicely cataloged submission. Figuring out what to work on is now about a million times easier; thanks again, guys.

- Everyone who submitted a bug report, patch or ticket comment. We can't possibly thank everyone by name – over 200 developers submitted patches that went into 0.96 – but everyone who's contributed to Django is listed in [AUTHORS](#).

## Django version 0.95 release notes

Welcome to the Django 0.95 release.

This represents a significant advance in Django development since the 0.91 release in January 2006. The details of every change in this release would be too extensive to list in full, but a summary is presented below.

### Suitability and API stability

This release is intended to provide a stable reference point for developers wanting to work on production-level applications that use Django.

However, it's not the 1.0 release, and we'll be introducing further changes before 1.0. For a clear look at which areas of the framework will change (and which ones will *not* change) before 1.0, see the `api-stability.txt` file, which lives in the `docs/` directory of the distribution.

You may have a need to use some of the features that are marked as “subject to API change” in that document, but that's OK with us as long as it's OK with you, and as long as you understand APIs may change in the future.

Fortunately, most of Django's core APIs won't be changing before version 1.0. There likely won't be as big of a change between 0.95 and 1.0 versions as there was between 0.91 and 0.95.

### Changes and new features

The major changes in this release (for developers currently using the 0.91 release) are a result of merging the ‘magic-removal’ branch of development. This branch removed a number of constraints in the way Django code had to be written that were a consequence of decisions made in the early days of Django, prior to its open-source release. It's now possible to write more natural, Pythonic code that works as expected, and there's less “black magic” happening behind the scenes.

Aside from that, another main theme of this release is a dramatic increase in usability. We've made countless improvements in error messages, documentation, etc., to improve developers' quality of life.

The new features and changes introduced in 0.95 include:

- Django now uses a more consistent and natural filtering interface for retrieving objects from the database.
- User-defined models, functions and constants now appear in the module namespace they were defined in. (Previously everything was magically transferred to the `django.models.*` namespace.)
- Some optional applications, such as the FlatPage, Sites and Redirects apps, have been decoupled and moved into `django.contrib`. If you don't want to use these applications, you no longer have to install their database tables.
- Django now has support for managing database transactions.
- We've added the ability to write custom authentication and authorization backends for authenticating users against alternate systems, such as LDAP.
- We've made it easier to add custom table-level functions to models, through a new “Manager” API.
- It's now possible to use Django without a database. This simply means that the framework no longer requires you to have a working database set up just to serve dynamic pages. In other words, you can just use `URLconfs/views`

on their own. Previously, the framework required that a database be configured, regardless of whether you actually used it.

- It's now more explicit and natural to override `save()` and `delete()` methods on models, rather than needing to hook into the `pre_save()` and `post_save()` method hooks.
- Individual pieces of the framework now can be configured without requiring the setting of an environment variable. This permits use of, for example, the Django templating system inside other applications.
- More and more parts of the framework have been internationalized, as we've expanded internationalization (i18n) support. The Django codebase, including code and templates, has now been translated, at least in part, into 31 languages. From Arabic to Chinese to Hungarian to Welsh, it is now possible to use Django's admin site in your native language.

The number of changes required to port from 0.91-compatible code to the 0.95 code base are significant in some cases. However, they are, for the most part, reasonably routine and only need to be done once. A list of the necessary changes is described in the [Removing The Magic](#) wiki page. There is also an easy [checklist](#) for reference when undertaking the porting operation.

## Problem reports and getting help

Need help resolving a problem with Django? The documentation in the distribution is also available [online](#) at the [Django website](#). The [FAQ](#) document is especially recommended, as it contains a number of issues that come up time and again.

For more personalized help, the [django-users](#) mailing list is a very active list, with more than 2,000 subscribers who can help you solve any sort of Django problem. We recommend you search the archives first, though, because many common questions appear with some regularity, and any particular problem may already have been answered.

Finally, for those who prefer the more immediate feedback offered by IRC, there's a [#django](#) channel on [irc.freenode.net](#) that is regularly populated by Django users and developers from around the world. Friendly people are usually available at any hour of the day – to help, or just to chat.

Thanks for using Django!

The Django Team July 2006

## 9.2 Security releases

Whenever a security issue is disclosed via [Django's security policies](#), appropriate release notes are now added to all affected release series.

Additionally, [an archive of disclosed security issues](#) is maintained.

### 9.2.1 Archive of security issues

Django's development team is strongly committed to responsible reporting and disclosure of security-related issues, as outlined in [Django's security policies](#).

As part of that commitment, we maintain the following historical list of issues which have been fixed and disclosed. For each issue, the list below includes the date, a brief description, the [CVE identifier](#) if applicable, a list of affected versions, a link to the full disclosure and links to the appropriate patch(es).

Some important caveats apply to this information:

- Lists of affected versions include only those versions of Django which had stable, security-supported releases at the time of disclosure. This means older versions (whose security support had expired) and versions which were in pre-release (alpha/beta/RC) states at the time of disclosure may have been affected, but are not listed.
- The Django project has on occasion issued security advisories, pointing out potential security problems which can arise from improper configuration or from other issues outside of Django itself. Some of these advisories have received CVEs; when that is the case, they are listed here, but as they have no accompanying patches or releases, only the description, disclosure and CVE will be listed.

### **Issues prior to Django’s security process**

Some security issues were handled before Django had a formalized security process in use. For these, new releases may not have been issued at the time and CVEs may not have been assigned.

#### **August 16, 2006 - CVE-2007-0404**

Filename validation issue in translation framework. [Full description](#)

#### **Versions affected**

- Django 0.90 (patch)
- Django 0.91 (patch)
- Django 0.95 (patch) (released January 21 2007)

#### **January 21, 2007 - CVE-2007-0405**

Apparent “caching” of authenticated user. [Full description](#)

#### **Versions affected**

- Django 0.95 (patch)

### **Issues under Django’s security process**

All other security issues have been handled under versions of Django’s security process. These are listed below.

#### **October 26, 2007 - CVE-2007-5712**

Denial-of-service via arbitrarily-large Accept-Language header. [Full description](#)

#### **Versions affected**

- Django 0.91 (patch)
- Django 0.95 (patch)
- Django 0.96 (patch)

### May 14, 2008 - CVE-2008-2302

XSS via admin login redirect. [Full description](#)

#### Versions affected

- Django 0.91 (patch)
- Django 0.95 (patch)
- Django 0.96 (patch)

### September 2, 2008 - CVE-2008-3909

CSRF via preservation of POST data during admin login. [Full description](#)

#### Versions affected

- Django 0.91 (patch)
- Django 0.95 (patch)
- Django 0.96 (patch)

### July 28, 2009 - CVE-2009-2659

Directory-traversal in development server media handler. [Full description](#)

#### Versions affected

- Django 0.96 (patch)
- Django 1.0 (patch)

### October 9, 2009 - CVE-2009-3965

Denial-of-service via pathological regular expression performance. [Full description](#)

#### Versions affected

- Django 1.0 (patch)
- Django 1.1 (patch)

### September 8, 2010 - CVE-2010-3082

XSS via trusting unsafe cookie value. [Full description](#)

### Versions affected

- Django 1.2 (patch)

### December 22, 2010 - CVE-2010-4534

Information leakage in administrative interface. [Full description](#)

### Versions affected

- Django 1.1 (patch)
- Django 1.2 (patch)

### December 22, 2010 - CVE-2010-4535

Denial-of-service in password-reset mechanism. [Full description](#)

### Versions affected

- Django 1.1 (patch)
- Django 1.2 (patch)

### February 8, 2011 - CVE-2011-0696

CSRF via forged HTTP headers. [Full description](#)

### Versions affected

- Django 1.1 (patch)
- Django 1.2 (patch)

### February 8, 2011 - CVE-2011-0697

XSS via unsanitized names of uploaded files. [Full description](#)

### Versions affected

- Django 1.1 (patch)
- Django 1.2 (patch)

### February 8, 2011 - CVE-2011-0698

Directory-traversal on Windows via incorrect path-separator handling. [Full description](#)

### Versions affected

- Django 1.1 (patch)
- Django 1.2 (patch)

### September 9, 2011 - CVE-2011-4136

Session manipulation when using memory-cache-backed session. [Full description](#)

### Versions affected

- Django 1.2 (patch)
- Django 1.3 (patch)

### September 9, 2011 - CVE-2011-4137

Denial-of-service via `URLField.verify_exists`. [Full description](#)

### Versions affected

- Django 1.2 (patch)
- Django 1.3 (patch)

### September 9, 2011 - CVE-2011-4138

Information leakage/arbitrary request issuance via `URLField.verify_exists`. [Full description](#)

### Versions affected

- Django 1.2: (patch)
- Django 1.3: (patch)

### September 9, 2011 - CVE-2011-4139

Host header cache poisoning. [Full description](#)

### Versions affected

- Django 1.2 (patch)
- Django 1.3 (patch)

### September 9, 2011 - CVE-2011-4140

Potential CSRF via `Host` header. [Full description](#)

#### Versions affected

This notification was an advisory only, so no patches were issued.

- Django 1.2
- Django 1.3

### July 30, 2012 - CVE-2012-3442

XSS via failure to validate redirect scheme. [Full description](#)

#### Versions affected

- Django 1.3: (patch)
- Django 1.4: (patch)

### July 30, 2012 - CVE-2012-3443

Denial-of-service via compressed image files. [Full description](#)

#### Versions affected

- Django 1.3: (patch)
- Django 1.4: (patch)

### July 30, 2012 - CVE-2012-3444

Denial-of-service via large image files. [Full description](#)

#### Versions affected

- Django 1.3 (patch)
- Django 1.4 (patch)

### October 17, 2012 - CVE-2012-4520

`Host` header poisoning. [Full description](#)

### Versions affected

- Django 1.3 (patch)
- Django 1.4 (patch)

### December 10, 2012 - No CVE 1

Additional hardening of Host header handling. [Full description](#)

### Versions affected

- Django 1.3 (patch)
- Django 1.4 (patch)

### December 10, 2012 - No CVE 2

Additional hardening of redirect validation. [Full description](#)

### Versions affected

- Django 1.3: (patch)
- Django 1.4: (patch)

### February 19, 2013 - No CVE

Additional hardening of Host header handling. [Full description](#)

### Versions affected

- Django 1.3 (patch)
- Django 1.4 (patch)

### February 19, 2013 - CVE-2013-1664 / CVE-2013-1665

Entity-based attacks against Python XML libraries. [Full description](#)

### Versions affected

- Django 1.3 (patch)
- Django 1.4 (patch)

### February 19, 2013 - CVE-2013-0305

Information leakage via admin history log. [Full description](#)

#### Versions affected

- Django 1.3 (patch)
- Django 1.4 (patch)

### February 19, 2013 - CVE-2013-0306

Denial-of-service via formset `max_num` bypass. [Full description](#)

#### Versions affected

- Django 1.3 (patch)
- Django 1.4 (patch)

### August 13, 2013 - CVE-2013-4249

XSS via admin trusting `URLField` values. [Full description](#)

#### Versions affected

- Django 1.5 (patch)

### August 13, 2013 - CVE-2013-6044

Possible XSS via unvalidated URL redirect schemes. [Full description](#)

#### Versions affected

- Django 1.4 (patch)
- Django 1.5 (patch)

### September 10, 2013 - CVE-2013-4315

Directory-traversal via `ssi` template tag. [Full description](#)

#### Versions affected

- Django 1.4 (patch)
- Django 1.5 (patch)

### September 14, 2013 - CVE-2013-1443

Denial-of-service via large passwords. [Full description](#)

#### Versions affected

- Django 1.4 (patch and Python compatibility fix)
- Django 1.5 (patch)

### April 21, 2014 - CVE-2014-0472

Unexpected code execution using `reverse()`. [Full description](#)

#### Versions affected

- Django 1.4 (patch)
- Django 1.5 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)

### April 21, 2014 - CVE-2014-0473

Caching of anonymous pages could reveal CSRF token. [Full description](#)

#### Versions affected

- Django 1.4 (patch)
- Django 1.5 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)

### April 21, 2014 - CVE-2014-0474

MySQL typecasting causes unexpected query results. [Full description](#)

#### Versions affected

- Django 1.4 (patch)
- Django 1.5 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)

### May 18, 2014 - CVE-2014-1418

Caches may be allowed to store and serve private data. [Full description](#)

#### Versions affected

- Django 1.4 (patch)
- Django 1.5 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)

### May 18, 2014 - CVE-2014-3730

Malformed URLs from user input incorrectly validated. [Full description](#)

#### Versions affected

- Django 1.4 (patch)
- Django 1.5 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)

### August 20, 2014 - CVE-2014-0480

`reverse()` can generate URLs pointing to other hosts. [Full description](#)

#### Versions affected

- Django 1.4 (patch)
- Django 1.5 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)

### August 20, 2014 - CVE-2014-0481

File upload denial of service. [Full description](#)

### Versions affected

- Django 1.4 (patch)
- Django 1.5 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)

### August 20, 2014 - CVE-2014-0482

RemoteUserMiddleware session hijacking. [Full description](#)

### Versions affected

- Django 1.4 (patch)
- Django 1.5 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)

### August 20, 2014 - CVE-2014-0483

Data leakage via querystring manipulation in admin. [Full description](#)

### Versions affected

- Django 1.4 (patch)
- Django 1.5 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)

### January 13, 2015 - CVE-2015-0219

WSGI header spoofing via underscore/dash conflation. [Full description](#)

### Versions affected

- Django 1.4 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)

### January 13, 2015 - CVE-2015-0220

Mitigated possible XSS attack via user-supplied redirect URLs. [Full description](#)

#### Versions affected

- Django 1.4 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)

### January 13, 2015 - CVE-2015-0221

Denial-of-service attack against `django.views.static.serve()`. [Full description](#)

#### Versions affected

- Django 1.4 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)

### January 13, 2015 - CVE-2015-0222

Database denial-of-service with `ModelMultipleChoiceField`. [Full description](#)

#### Versions affected

- Django 1.6 (patch)
- Django 1.7 (patch)

### March 9, 2015 - CVE-2015-2241

XSS attack via properties in `ModelAdmin.readonly_fields`. [Full description](#)

#### Versions affected

- Django 1.7 (patch)
- Django 1.8 (patch)

### March 18, 2015 - CVE-2015-2316

Denial-of-service possibility with `strip_tags()`. [Full description](#)

### Versions affected

- Django 1.6 (patch)
- Django 1.7 (patch)
- Django 1.8 (patch)

### March 18, 2015 - CVE-2015-2317

Mitigated possible XSS attack via user-supplied redirect URLs. [Full description](#)

### Versions affected

- Django 1.4 (patch)
- Django 1.6 (patch)
- Django 1.7 (patch)
- Django 1.8 (patch)

### May 20, 2015 - CVE-2015-3982

Fixed session flushing in the `cached_db` backend. [Full description](#)

### Versions affected

- Django 1.8 (patch)

### July 8, 2015 - CVE-2015-5143

Denial-of-service possibility by filling session store. [Full description](#)

### Versions affected

- Django 1.8 (patch)
- Django 1.7 (patch)
- Django 1.4 (patch)

### July 8, 2015 - CVE-2015-5144

Header injection possibility since validators accept newlines in input. [Full description](#)

### Versions affected

- Django 1.8 (patch)
- Django 1.7 (patch)
- Django 1.4 (patch)

### July 8, 2015 - CVE-2015-5145

Denial-of-service possibility in URL validation. [Full description](#)

### Versions affected

- Django 1.8 (patch)

### August 18, 2015 - CVE-2015-5963 / CVE-2015-5964

Denial-of-service possibility in `logout ()` view by filling session store. [Full description](#)

### Versions affected

- Django 1.8 (patch)
- Django 1.7 (patch)
- Django 1.4 (patch)

### November 24, 2015 - CVE-2015-8213

Settings leak possibility in `date` template filter. [Full description](#)

### Versions affected

- Django 1.8 (patch)
- Django 1.7 (patch)

### February 1, 2016 - CVE-2016-2048

User with “change” but not “add” permission can create objects for `ModelAdmin`’s with `save_as=True`. [Full description](#)

### Versions affected

- Django 1.9 (patch)

### March 1, 2016 - CVE-2016-2512

Malicious redirect and possible XSS attack via user-supplied redirect URLs containing basic auth. [Full description](#)

#### Versions affected

- Django 1.9 (patch)
- Django 1.8 (patch)

### March 1, 2016 - CVE-2016-2513

User enumeration through timing difference on password hasher work factor upgrade. [Full description](#)

#### Versions affected

- Django 1.9 (patch)
- Django 1.8 (patch)

### July 18, 2016 - CVE-2016-6186

XSS in admin's add/change related popup. [Full description](#)

#### Versions affected

- Django 1.9 (patch)
- Django 1.8 (patch)

### September 26, 2016 - CVE-2016-7401

CSRF protection bypass on a site with Google Analytics. [Full description](#)

#### Versions affected

- Django 1.9 (patch)
- Django 1.8 (patch)

### November 1, 2016 - CVE-2016-9013

User with hardcoded password created when running tests on Oracle. [Full description](#)

### Versions affected

- Django 1.10 (patch)
- Django 1.9 (patch)
- Django 1.8 (patch)

### November 1, 2016 - CVE-2016-9014

DNS rebinding vulnerability when `DEBUG=True`. [Full description](#)

### Versions affected

- Django 1.10 (patch)
- Django 1.9 (patch)
- Django 1.8 (patch)

### April 4, 2017 - CVE-2017-7233

Open redirect and possible XSS attack via user-supplied numeric redirect URLs. [Full description](#)

### Versions affected

- Django 1.10 (patch)
- Django 1.9 (patch)
- Django 1.8 (patch)

### April 4, 2017 - CVE-2017-7234

Open redirect vulnerability in `django.views.static.serve()`. [Full description](#)

### Versions affected

- Django 1.10 (patch)
- Django 1.9 (patch)
- Django 1.8 (patch)

### September 5, 2017 - CVE-2017-12794

Possible XSS in traceback section of technical 500 debug page. [Full description](#)

### Versions affected

- Django 1.11 (patch)
- Django 1.10 (patch)

Documentation for people hacking on Django itself. This is the place to go if you'd like to help improve Django or learn about how Django is managed.

### 10.1 Contributing to Django

Django is a community that lives on its volunteers. As it keeps growing, we always need more people to help others. As soon as you learn Django, you can contribute in many ways:

- Join the *django-users* mailing list and answer questions. This mailing list has a huge audience, and we really want to maintain a friendly and helpful atmosphere. If you're new to the Django community, you should read the [posting guidelines](#).
- Join the [#django IRC channel](#) on Freenode and answer questions. By explaining Django to other users, you're going to learn a lot about the framework yourself.
- Blog about Django. We syndicate all the Django blogs we know about on the [community page](#); if you'd like to see your blog on that page you can [register it here](#).
- Contribute to open-source Django projects, write some documentation, or release your own code as an open-source pluggable application. The ecosystem of pluggable applications is a big strength of Django, help us build it!

If you think working *with* Django is fun, wait until you start working *on* it. We're passionate about helping Django users make the jump to contributing members of the community, so there are several ways you can help Django's development:

- *Report bugs* in our [ticket tracker](#).
- Join the *django-developers* mailing list and share your ideas for how to improve Django. We're always open to suggestions.
- *Submit patches* for new and/or fixed behavior. If you're looking for an easy way to start contributing to Django read the *Writing your first patch for Django* tutorial and have a look at the [easy pickings](#) tickets. The *Patch review checklist* will also be helpful.

- *Improve the documentation or write unit tests.*
- *Triage tickets and review patches* created by other users.

Really, **ANYONE** can do something to help make Django better and greater!

Browse the following sections to find out how:

## 10.1.1 Advice for new contributors

New contributor and not sure what to do? Want to help but just don't know how to get started? This is the section for you.

---

### Basic tools and workflow

If you are new to contributing to Django, the *Writing your first patch for Django* tutorial will give you an introduction to the tools and the workflow.

---

### First steps

Start with these easy tasks to discover Django's development process.

- **Sign the Contributor License Agreement**

The code that you write belongs to you or your employer. If your contribution is more than one or two lines of code, you need to sign the [CLA](#). See the [Contributor License Agreement FAQ](#) for a more thorough explanation.

- **Triage tickets**

If an [unreviewed ticket](#) reports a bug, try and reproduce it. If you can reproduce it and it seems valid, make a note that you confirmed the bug and accept the ticket. Make sure the ticket is filed under the correct component area. Consider writing a patch that adds a test for the bug's behavior, even if you don't fix the bug itself. See more at *How can I help with triaging?*

- **Look for tickets that are accepted and review patches to build familiarity with the codebase and the process**

Mark the appropriate flags if a patch needs docs or tests. Look through the changes a patch makes, and keep an eye out for syntax that is incompatible with older but still supported versions of Python. *Run the tests* and make sure they pass. Where possible and relevant, try them out on a database other than SQLite. Leave comments and feedback!

- **Keep old patches up to date**

Oftentimes the codebase will change between a patch being submitted and the time it gets reviewed. Make sure it still applies cleanly and functions as expected. Simply updating a patch is both useful and important! See more on *Submitting patches*.

- **Write some documentation**

Django's documentation is great but it can always be improved. Did you find a typo? Do you think that something should be clarified? Go ahead and suggest a documentation patch! See also the guide on *Writing documentation*.

---

**Note:** The [reports page](#) contains links to many useful Trac queries, including several that are useful for triaging tickets and reviewing patches as suggested above.

---

## Guidelines

As a newcomer on a large project, it's easy to experience frustration. Here's some advice to make your work on Django more useful and rewarding.

- **Pick a subject area that you care about, that you are familiar with, or that you want to learn about**

You don't already have to be an expert on the area you want to work on; you become an expert through your ongoing contributions to the code.

- **Analyze tickets' context and history**

Trac isn't an absolute; the context is just as important as the words. When reading Trac, you need to take into account who says things, and when they were said. Support for an idea two years ago doesn't necessarily mean that the idea will still have support. You also need to pay attention to who *hasn't* spoken – for example, if a core team member hasn't been recently involved in a discussion, then a ticket may not have the support required to get into trunk.

- **Start small**

It's easier to get feedback on a little issue than on a big one. See the [easy pickings](#).

- **If you're going to engage in a big task, make sure that your idea has support first**

This means getting someone else to confirm that a bug is real before you fix the issue, and ensuring that the core team supports a proposed feature before you go implementing it.

- **Be bold! Leave feedback!**

Sometimes it can be scary to put your opinion out to the world and say “this ticket is correct” or “this patch needs work”, but it's the only way the project moves forward. The contributions of the broad Django community ultimately have a much greater impact than that of the core team. We can't do it without **you!**

- **Err on the side of caution when marking things Ready For Check-in**

If you're really not certain if a ticket is ready, don't mark it as such. Leave a comment instead, letting others know your thoughts. If you're mostly certain, but not completely certain, you might also try asking on IRC to see if someone else can confirm your suspicions.

- **Wait for feedback, and respond to feedback that you receive**

Focus on one or two tickets, see them through from start to finish, and repeat. The shotgun approach of taking on lots of tickets and letting some fall by the wayside ends up doing more harm than good.

- **Be rigorous**

When we say “**PEP 8**, and must have docs and tests”, we mean it. If a patch doesn't have docs and tests, there had better be a good reason. Arguments like “I couldn't find any existing tests of this feature” don't carry much weight—while it may be true, that means you have the extra-important job of writing the very first tests for that feature, not that you get a pass from writing tests altogether.

## FAQ

1. **This ticket I care about has been ignored for days/weeks/months! What can I do to get it committed?**

First off, it's not personal. Django is entirely developed by volunteers (even the core team), and sometimes folks just don't have time. The best thing to do is to send a gentle reminder to the [django-developers](#) mailing list asking for review on the ticket, or to bring it up in the [#django-dev](#) IRC channel.

2. **I'm sure my ticket is absolutely 100% perfect, can I mark it as RFC myself?**

Short answer: No. It's always better to get another set of eyes on a ticket. If you're having trouble getting that second set of eyes, see question 1, above.

## 10.1.2 Reporting bugs and requesting features

---

**Important:** Please report security issues **only** to [security@djangoproject.com](mailto:security@djangoproject.com). This is a private list only open to long-time, highly trusted Django developers, and its archives are not public. For further details, please see *our security policies*.

---

Otherwise, before reporting a bug or requesting a new feature, please consider these general points:

- Check that someone hasn't already filed the bug or feature request by [searching](#) or running [custom queries](#) in the ticket tracker.
- Don't use the ticket system to ask support questions. Use the [django-users](#) list or the [#django](#) IRC channel for that.
- Don't reopen issues that have been marked “wontfix” by a core developer. This mark means that the decision has been made that we can't or won't fix this particular issue. If you're not sure why, please ask on [django-developers](#).
- Don't use the ticket tracker for lengthy discussions, because they're likely to get lost. If a particular ticket is controversial, please move the discussion to [django-developers](#).

### Reporting bugs

Well-written bug reports are *incredibly* helpful. However, there's a certain amount of overhead involved in working with any bug tracking system so your help in keeping our ticket tracker as useful as possible is appreciated. In particular:

- **Do** read the [FAQ](#) to see if your issue might be a well-known question.
- **Do** ask on [django-users](#) or [#django](#) *first* if you're not sure if what you're seeing is a bug.
- **Do** write complete, reproducible, specific bug reports. You must include a clear, concise description of the problem, and a set of instructions for replicating it. Add as much debug information as you can: code snippets, test cases, exception backtraces, screenshots, etc. A nice small test case is the best way to report a bug, as it gives us an easy way to confirm the bug quickly.
- **Don't** post to [django-developers](#) just to announce that you have filed a bug report. All the tickets are mailed to another list, [django-updates](#), which is tracked by developers and interested community members; we see them as they are filed.

To understand the lifecycle of your ticket once you have created it, refer to [Triaging tickets](#).

### Reporting user interface bugs and features

If your bug or feature request touches on anything visual in nature, there are a few additional guidelines to follow:

- Include screenshots in your ticket which are the visual equivalent of a minimal testcase. Show off the issue, not the crazy customizations you've made to your browser.
- If the issue is difficult to show off using a still image, consider capturing a *brief* screencast. If your software permits it, capture only the relevant area of the screen.
- If you're offering a patch which changes the look or behavior of Django's UI, you **must** attach before *and* after screenshots/screencasts. Tickets lacking these are difficult for triagers and core developers to assess quickly.
- Screenshots don't absolve you of other good reporting practices. Make sure to include URLs, code snippets, and step-by-step instructions on how to reproduce the behavior visible in the screenshots.

- Make sure to set the UI/UX flag on the ticket so interested parties can find your ticket.

## Requesting features

We're always trying to make Django better, and your feature requests are a key part of that. Here are some tips on how to make a request most effectively:

- Make sure the feature actually requires changes in Django's core. If your idea can be developed as an independent application or module — for instance, you want to support another database engine — we'll probably suggest that you to develop it independently. Then, if your project gathers sufficient community support, we may consider it for inclusion in Django.
- First request the feature on the *django-developers* list, not in the ticket tracker. It'll get read more closely if it's on the mailing list. This is even more important for large-scale feature requests. We like to discuss any big changes to Django's core on the mailing list before actually working on them.
- Describe clearly and concisely what the missing feature is and how you'd like to see it implemented. Include example code (non-functional is OK) if possible.
- Explain *why* you'd like the feature. In some cases this is obvious, but since Django is designed to help real developers get real work done, you'll need to explain it, if it isn't obvious why the feature would be useful.

If core developers agree on the feature, then it's appropriate to create a ticket. Include a link the discussion on *django-developers* in the ticket description.

As with most open-source projects, code talks. If you are willing to write the code for the feature yourself or, even better, if you've already written it, it's much more likely to be accepted. Just fork Django on GitHub, create a feature branch, and show us your work!

See also: *Documenting new features*.

## How we make decisions

Whenever possible, we strive for a rough consensus. To that end, we'll often have informal votes on *django-developers* about a feature. In these votes we follow the voting style invented by Apache and used on Python itself, where votes are given as +1, +0, -0, or -1. Roughly translated, these votes mean:

- +1: "I love the idea and I'm strongly committed to it."
- +0: "Sounds OK to me."
- -0: "I'm not thrilled, but I won't stand in the way."
- -1: "I strongly disagree and would be very unhappy to see the idea turn into reality."

Although these votes on *django-developers* are informal, they'll be taken very seriously. After a suitable voting period, if an obvious consensus arises we'll follow the votes.

However, consensus is not always possible. If consensus cannot be reached, or if the discussion towards a consensus fizzles out without a concrete decision, any *core team member* may defer the decision to the *technical board*.

Internally, the technical board will use the same voting mechanism. A proposition will be considered carried if:

- There are at least three "+1" votes from members of the technical board.
- There is no "-1" vote from any member of the technical board.

Votes should be submitted within a week.

Since this process allows any technical board member to veto a proposal, a "-1" vote should be accompanied by an explanation of what it would take to convert that "-1" into at least a "+0".

Votes on technical matters should be announced and held in public on the *django-developers* mailing list.

### 10.1.3 Triageing tickets

Django uses *Trac* for managing the work on the code base. *Trac* is a community-tended garden of the bugs people have found and the features people would like to see added. As in any garden, sometimes there are weeds to be pulled and sometimes there are flowers and vegetables that need picking. We need your help to sort out one from the other, and in the end we all benefit together.

Like all gardens, we can aspire to perfection but in reality there's no such thing. Even in the most pristine garden there are still snails and insects. In a community garden there are also helpful people who – with the best of intentions – fertilize the weeds and poison the roses. It's the job of the community as a whole to self-manage, keep the problems to a minimum, and educate those coming into the community so that they can become valuable contributing members.

Similarly, while we aim for *Trac* to be a perfect representation of the state of Django's progress, we acknowledge that this simply will not happen. By distributing the load of *Trac* maintenance to the community, we accept that there will be mistakes. *Trac* is “mostly accurate”, and we give allowances for the fact that sometimes it will be wrong. That's okay. We're perfectionists with deadlines.

We rely on the community to keep participating, keep tickets as accurate as possible, and raise issues for discussion on our mailing lists when there is confusion or disagreement.

Django is a community project, and every contribution helps. We can't do this without **you!**

#### Triage workflow

Unfortunately, not all bug reports and feature requests in the ticket tracker provide all the *required details*. A number of tickets have patches, but those patches don't meet all the requirements of a *good patch*.

One way to help out is to *triage* tickets that have been created by other users. The core team and several community members work on this regularly, but more help is always appreciated.

Most of the workflow is based around the concept of a ticket's *triage stages*. Each stage describes where in its lifetime a given ticket is at any time. Along with a handful of flags, this attribute easily tells us what and who each ticket is waiting on.

Since a picture is worth a thousand words, let's start there:

We've got two roles in this diagram:

- Committers (also called core developers): people with commit access who are responsible for making decisions and integrating the contributions of the community.
- Ticket triagers: anyone in the Django community who chooses to become involved in Django's development process. Our Trac installation is intentionally left open to the public, and anyone can triage tickets. Django is a community project, and we encourage *triage by the community*.

By way of example, here we see the lifecycle of an average ticket:

- Alice creates a ticket, and uploads an incomplete patch (no tests, incorrect implementation).
- Bob reviews the patch, marks it "Accepted", "needs tests", and "patch needs improvement", and leaves a comment telling Alice how the patch could be improved.
- Alice updates the patch, adding tests (but not changing the implementation). She removes the two flags.
- Charlie reviews the patch and resets the "patch needs improvement" flag with another comment about improving the implementation.
- Alice updates the patch, fixing the implementation. She removes the "patch needs improvement" flag.
- Daisy reviews the patch, and marks it RFC.
- Jacob, a core developer, reviews the RFC patch, applies it to his checkout, and commits it.

Some tickets require much less feedback than this, but then again some tickets require much much more.

## Triage stages

Below we describe in more detail the various stages that a ticket may flow through during its lifetime.

### Unreviewed

The ticket has not been reviewed by anyone who felt qualified to make a judgment about whether the ticket contained a valid issue, a viable feature, or ought to be closed for any of the various reasons.

### Accepted

The big gray area! The absolute meaning of “accepted” is that the issue described in the ticket is valid and is in some stage of being worked on. Beyond that there are several considerations:

- **Accepted + No Flags**

The ticket is valid, but no one has submitted a patch for it yet. Often this means you could safely start writing a patch for it. This is generally more true for the case of accepted bugs than accepted features. A ticket for a bug that has been accepted means that the issue has been verified by at least one triager as a legitimate bug - and should probably be fixed if possible. An accepted new feature may only mean that one triager thought the feature would be good to have, but this alone does not represent a consensus view or imply with any certainty that a patch will be accepted for that feature. Seek more feedback before writing an extensive patch if you are in doubt.

- **Accepted + Has Patch**

The ticket is waiting for people to review the supplied patch. This means downloading the patch and trying it out, verifying that it contains tests and docs, running the test suite with the included patch, and leaving feedback on the ticket.

- **Accepted + Has Patch + Needs ...**

This means the ticket has been reviewed, and has been found to need further work. “Needs tests” and “Needs documentation” are self-explanatory. “Patch needs improvement” will generally be accompanied by a comment on the ticket explaining what is needed to improve the code.

### Ready For Checkin

The ticket was reviewed by any member of the community other than the person who supplied the patch and found to meet all the requirements for a commit-ready patch. A committer now needs to give the patch a final review prior to being committed. See the *New contributors' FAQ* for “My ticket has been in RFC forever! What should I do?”

### Someday/Maybe

This stage isn't shown on the diagram. It's only used by core developers to keep track of high-level ideas or long term feature requests.

These tickets are uncommon and overall less useful since they don't describe concrete actionable issues. They are enhancement requests that we might consider adding someday to the framework if an excellent patch is submitted. They are not a high priority.

## Other triage attributes

A number of flags, appearing as checkboxes in Trac, can be set on a ticket:

### Has patch

This means the ticket has an associated *patch*. These will be reviewed to see if the patch is “good”.

The following three fields (Needs documentation, Needs tests, Patch needs improvement) apply only if a patch has been supplied.

### Needs documentation

This flag is used for tickets with patches that need associated documentation. Complete documentation of features is a prerequisite before we can check them into the codebase.

### Needs tests

This flags the patch as needing associated unit tests. Again, this is a required part of a valid patch.

### Patch needs improvement

This flag means that although the ticket *has* a patch, it’s not quite ready for checkin. This could mean the patch no longer applies cleanly, there is a flaw in the implementation, or that the code doesn’t meet our standards.

### Easy pickings

Tickets that would require small, easy, patches.

### Type

Tickets should be categorized by *type* between:

- **New Feature** For adding something new.
- **Bug** For when an existing thing is broken or not behaving as expected.
- **Cleanup/optimization** For when nothing is broken but something could be made cleaner, better, faster, stronger.

### Component

Tickets should be classified into *components* indicating which area of the Django codebase they belong to. This makes tickets better organized and easier to find.

## Severity

The *severity* attribute is used to identify blockers, that is, issues which should get fixed before releasing the next version of Django. Typically those issues are bugs causing regressions from earlier versions or potentially causing severe data losses. This attribute is quite rarely used and the vast majority of tickets have a severity of “Normal”.

## Version

It is possible to use the *version* attribute to indicate in which version the reported bug was identified.

## UI/UX

This flag is used for tickets that relate to User Interface and User Experiences questions. For example, this flag would be appropriate for user-facing features in forms or the admin interface.

## Cc

You may add your username or email address to this field to be notified when new contributions are made to the ticket.

## Keywords

With this field you may label a ticket with multiple keywords. This can be useful, for example, to group several tickets of a same theme. Keywords can either be comma or space separated. Keyword search finds the keyword string anywhere in the keywords. For example, clicking on a ticket with the keyword “form” will yield similar tickets tagged with keywords containing strings such as “formset”, “modelformset”, and “ManagementForm”.

## Closing Tickets

When a ticket has completed its useful lifecycle, it’s time for it to be closed. Closing a ticket is a big responsibility, though. You have to be sure that the issue is really resolved, and you need to keep in mind that the reporter of the ticket may not be happy to have their ticket closed (unless it’s fixed, of course). If you’re not certain about closing a ticket, just leave a comment with your thoughts instead.

If you do close a ticket, you should always make sure of the following:

- Be certain that the issue is resolved.
- Leave a comment explaining the decision to close the ticket.
- If there is a way they can improve the ticket to reopen it, let them know.
- If the ticket is a duplicate, reference the original ticket. Also cross-reference the closed ticket by leaving a comment in the original one – this allows to access more related information about the reported bug or requested feature.
- **Be polite.** No one likes having their ticket closed. It can be frustrating or even discouraging. The best way to avoid turning people off from contributing to Django is to be polite and friendly and to offer suggestions for how they could improve this ticket and other tickets in the future.

A ticket can be resolved in a number of ways:

- **fixed** Used by the core developers once a patch has been rolled into Django and the issue is fixed.

- **invalid** Used if the ticket is found to be incorrect. This means that the issue in the ticket is actually the result of a user error, or describes a problem with something other than Django, or isn't a bug report or feature request at all (for example, some new users submit support queries as tickets).
- **wontfix** Used when a core developer decides that this request is not appropriate for consideration in Django. This is usually chosen after discussion in the *django-developers* mailing list. Feel free to start or join in discussions of “wontfix” tickets on the *django-developers* mailing list, but please do not reopen tickets closed as “wontfix” by a *core developer*.
- **duplicate** Used when another ticket covers the same issue. By closing duplicate tickets, we keep all the discussion in one place, which helps everyone.
- **worksforme** Used when the ticket doesn't contain enough detail to replicate the original bug.
- **needsinfo** Used when the ticket does not contain enough information to replicate the reported issue but is potentially still valid. The ticket should be reopened when more information is supplied.

If you believe that the ticket was closed in error – because you're still having the issue, or it's popped up somewhere else, or the triagers have made a mistake – please reopen the ticket and provide further information. Again, please do not reopen tickets that have been marked as “wontfix” by core developers and bring the issue to *django-developers* instead.

## How can I help with triaging?

The triage process is primarily driven by community members. Really, **ANYONE** can help.

Core developers may provide feedback on issues they're familiar with, or make decisions on controversial ones, but they aren't responsible for triaging tickets in general.

To get involved, start by [creating an account on Trac](#). If you have an account but have forgotten your password, you can reset it using the [password reset page](#).

Then, you can help out by:

- Closing “Unreviewed” tickets as “invalid”, “worksforme” or “duplicate.”
- Closing “Unreviewed” tickets as “needsinfo” when the description is too sparse to be actionable, or when they're feature requests requiring a discussion on *django-developers*.
- Correcting the “Needs tests”, “Needs documentation”, or “Has patch” flags for tickets where they are incorrectly set.
- Setting the “Easy pickings” flag for tickets that are small and relatively straightforward.
- Set the *type* of tickets that are still uncategorized.
- Checking that old tickets are still valid. If a ticket hasn't seen any activity in a long time, it's possible that the problem has been fixed but the ticket hasn't yet been closed.
- Identifying trends and themes in the tickets. If there are a lot of bug reports about a particular part of Django, it may indicate we should consider refactoring that part of the code. If a trend is emerging, you should raise it for discussion (referencing the relevant tickets) on *django-developers*.
- Verify if patches submitted by other users are correct. If they are correct and also contain appropriate documentation and tests then move them to the “Ready for Checkin” stage. If they are not correct then leave a comment to explain why and set the corresponding flags (“Patch needs improvement”, “Needs tests” etc.).

---

**Note:** The [Reports page](#) contains links to many useful Trac queries, including several that are useful for triaging tickets and reviewing patches as suggested above.

You can also find more *Advice for new contributors*.

---

However, we do ask the following of all general community members working in the ticket database:

- Please **don't** close tickets as “wontfix.” The core developers will make the final determination of the fate of a ticket, usually after consultation with the community.
- Please **don't** promote your own tickets to “Ready for checkin”. You may mark other people’s tickets which you’ve reviewed as “Ready for checkin”, but you should get at minimum one other community member to review a patch that you submit.
- Please **don't** reverse a decision that has been made by a *core developer*. If you disagree with a decision that has been made, please post a message to *django-developers*.
- If you’re unsure if you should be making a change, don’t make the change but instead leave a comment with your concerns on the ticket, or post a message to *django-developers*. It’s okay to be unsure, but your input is still valuable.

## Bisecting a regression

A regression is a bug that’s present in some newer version of Django but not in an older one. An extremely helpful piece of information is the commit that introduced the regression. Knowing the commit that caused the change in behavior helps identify if the change was intentional or if it was an inadvertent side-effect. Here’s how you can determine this.

Begin by writing a regression test for Django’s test suite for the issue. For example, we’ll pretend we’re debugging a regression in migrations. After you’ve written the test and confirmed that it fails on the latest master, put it in a separate file that you can run standalone. For our example, we’ll pretend we created `tests/migrations/test_regression.py`, which can be run with:

```
$ ./runtests.py migrations.test_regression
```

Next, we mark the current point in history as being “bad” since the test fails:

```
$ git bisect bad
You need to start by "git bisect start"
Do you want me to do it for you [Y/n]? y
```

Now, we need to find a point in git history before the regression was introduced (i.e. a point where the test passes). Use something like `git checkout HEAD~100` to checkout an earlier revision (100 commits earlier, in this case). Check if the test fails. If so, mark that point as “bad” (`git bisect bad`), then checkout an earlier revision and recheck. Once you find a revision where your test passes, mark it as “good”:

```
$ git bisect good
Bisecting: X revisions left to test after this (roughly Y steps)
...
```

Now we’re ready for the fun part: using `git bisect run` to automate the rest of the process:

```
$ git bisect run tests/runtests.py migrations.test_regression
```

You should see `git bisect` use a binary search to automatically checkout revisions between the good and bad commits until it finds the first “bad” commit where the test fails.

Now, report your results on the Trac ticket, and please include the regression test as an attachment. When someone writes a fix for the bug, they’ll already have your test as a starting point.

## 10.1.4 Writing code

So you'd like to write some code to improve Django. Awesome! Browse the following sections to find out how to give your code patches the best chances to be included in Django core:

### Coding style

Please follow these coding standards when writing code for inclusion in Django.

### Python style

- Please conform to the indentation style dictated in the `.editorconfig` file. We recommend using a text editor with `EditorConfig` support to avoid indentation and whitespace issues. The Python files use 4 spaces for indentation and the HTML files use 2 spaces.

- Unless otherwise specified, follow **PEP 8**.

Use `flake8` to check for problems in this area. Note that our `setup.cfg` file contains some excluded files (deprecated modules we don't care about cleaning up and some third-party code that Django vendors) as well as some excluded errors that we don't consider as gross violations. Remember that **PEP 8** is only a guide, so respect the style of the surrounding code as a primary goal.

An exception to **PEP 8** is our rules on line lengths. Don't limit lines of code to 79 characters if it means the code looks significantly uglier or is harder to read. We allow up to 119 characters as this is the width of GitHub code review; anything longer requires horizontal scrolling which makes review more difficult. This check is included when you run `flake8`. Documentation, comments, and docstrings should be wrapped at 79 characters, even though **PEP 8** suggests 72.

- Use four spaces for indentation.
- Use underscores, not camelCase, for variable, function and method names (i.e. `poll.get_unique_voters()`, not `poll.getUniqueVoters`).
- Use `InitialCaps` for class names (or for factory functions that return classes).
- In docstrings, follow **PEP 257**. For example:

```
def foo():
    """
    Calculate something and return the result.
    """
    ...
```

- In tests, use `assertRaisesMessage()` instead of `assertRaises()` so you can check the exception message. Use `assertRaisesRegex()` (`six.assertRaisesRegex()` as long as we support Python 2) only if you need to use regular expression matching.

### Imports

- Use `isort` to automate import sorting using the guidelines below.

Quick start:

```
$ pip install isort
$ isort -rc .
```

This runs `isort` recursively from your current directory, modifying any files that don't conform to the guidelines. If you need to have imports out of order (to avoid a circular import, for example) use a comment like this:

```
import module # isort:skip
```

- Put imports in these groups: future, standard library, third-party libraries, other Django components, local Django component, try/excepts. Sort lines in each group alphabetically by the full module name. Place all `import module` statements before `from module import objects` in each section. Use absolute imports for other Django components and relative imports for local components.
- On each line, alphabetize the items with the upper case items grouped before the lower case items.
- Break long lines using parentheses and indent continuation lines by 4 spaces. Include a trailing comma after the last import and put the closing parenthesis on its own line.

Use a single blank line between the last import and any module level code, and use two blank lines above the first function or class.

For example (comments are for explanatory purposes only):

```
django/contrib/admin/example.py

# future
from __future__ import unicode_literals

# standard library
import json
from itertools import chain

# third-party
import bcrypt

# Django
from django.http import Http404
from django.http.response import (
    Http404, HttpResponse, HttpResponseNotAllowed, StreamingHttpResponse,
    cookie,
)

# local Django
from .models import LogEntry

# try/except
try:
    import pytz
except ImportError:
    pytz = None

CONSTANT = 'foo'

class Example(object):
    # ...
```

- Use convenience imports whenever available. For example, do this:

```
from django.views import View
```

instead of:

```
from django.views.generic.base import View
```

## Template style

- In Django template code, put one (and only one) space between the curly brackets and the tag contents.

Do this:

```
{{ foo }}
```

Don't do this:

```
{{foo}}
```

## View style

- In Django views, the first parameter in a view function should be called `request`.

Do this:

```
def my_view(request, foo):  
    # ...
```

Don't do this:

```
def my_view(req, foo):  
    # ...
```

## Model style

- Field names should be all lowercase, using underscores instead of camelCase.

Do this:

```
class Person(models.Model):  
    first_name = models.CharField(max_length=20)  
    last_name = models.CharField(max_length=40)
```

Don't do this:

```
class Person(models.Model):  
    First_Name = models.CharField(max_length=20)  
    Last_Name = models.CharField(max_length=40)
```

- The class `Meta` should appear *after* the fields are defined, with a single blank line separating the fields and the class definition.

Do this:

```
class Person(models.Model):  
    first_name = models.CharField(max_length=20)  
    last_name = models.CharField(max_length=40)  
  
    class Meta:
```

```
class Meta:
    verbose_name_plural = 'people'
```

Don't do this:

```
class Person(models.Model):
    first_name = models.CharField(max_length=20)
    last_name = models.CharField(max_length=40)
    class Meta:
        verbose_name_plural = 'people'
```

Don't do this, either:

```
class Person(models.Model):
    class Meta:
        verbose_name_plural = 'people'

    first_name = models.CharField(max_length=20)
    last_name = models.CharField(max_length=40)
```

- If you define a `__str__` method (previously `__unicode__` before Python 3 was supported), decorate the model class with `python_2_unicode_compatible()`.
- The order of model inner classes and standard methods should be as follows (noting that these are not all required):
  - All database fields
  - Custom manager attributes
  - class Meta
  - def `__str__()`
  - def `save()`
  - def `get_absolute_url()`
  - Any custom methods
- If `choices` is defined for a given model field, define each choice as a tuple of tuples, with an all-upercase name as a class attribute on the model. Example:

```
class MyModel(models.Model):
    DIRECTION_UP = 'U'
    DIRECTION_DOWN = 'D'
    DIRECTION_CHOICES = (
        (DIRECTION_UP, 'Up'),
        (DIRECTION_DOWN, 'Down'),
    )
```

## Use of `django.conf.settings`

Modules should not in general use settings stored in `django.conf.settings` at the top level (i.e. evaluated when the module is imported). The explanation for this is as follows:

Manual configuration of settings (i.e. not relying on the `DJANGO_SETTINGS_MODULE` environment variable) is allowed and possible as follows:

```
from django.conf import settings

settings.configure({}, SOME_SETTING='foo')
```

However, if any setting is accessed before the `settings.configure` line, this will not work. (Internally, `settings` is a `LazyObject` which configures itself automatically when the settings are accessed if it has not already been configured).

So, if there is a module containing some code as follows:

```
from django.conf import settings
from django.urls import get_callable

default_foo_view = get_callable(settings.FOO_VIEW)
```

...then importing this module will cause the settings object to be configured. That means that the ability for third parties to import the module at the top level is incompatible with the ability to configure the settings object manually, or makes it very difficult in some circumstances.

Instead of the above code, a level of laziness or indirection must be used, such as `django.utils.functional.LazyObject`, `django.utils.functional.lazy()` or `lambda`.

## Miscellaneous

- Mark all strings for internationalization; see the *i18n documentation* for details.
- Remove `import` statements that are no longer used when you change code. `flake8` will identify these imports for you. If an unused import needs to remain for backwards-compatibility, mark the end of with `# NOQA` to silence the `flake8` warning.
- Systematically remove all trailing whitespaces from your code as those add unnecessary bytes, add visual clutter to the patches and can also occasionally cause unnecessary merge conflicts. Some IDE's can be configured to automatically remove them and most VCS tools can be set to highlight them in diff outputs.
- Please don't put your name in the code you contribute. Our policy is to keep contributors' names in the `AUTHORS` file distributed with Django – not scattered throughout the codebase itself. Feel free to include a change to the `AUTHORS` file in your patch if you make more than a single trivial change.

## JavaScript style

For details about the JavaScript code style used by Django, see *JavaScript*.

## Unit tests

Django comes with a test suite of its own, in the `tests` directory of the code base. It's our policy to make sure all tests pass at all times.

We appreciate any and all contributions to the test suite!

The Django tests all use the testing infrastructure that ships with Django for testing applications. See *Writing and running tests* for an explanation of how to write new tests.

## Running the unit tests

### Quickstart

First, fork Django on GitHub.

Second, create and activate a virtual environment. If you're not familiar with how to do that, read our *contributing tutorial*.

Next, clone your fork, install some requirements, and run the tests:

```
$ git clone git@github.com:YourGitHubName/django.git django-repo
$ cd django-repo/tests
$ pip install -e ..
$ pip install -r requirements/py3.txt # Python 2: py2.txt
$ ./runtests.py
```

Installing the requirements will likely require some operating system packages that your computer doesn't have installed. You can usually figure out which package to install by doing a Web search for the last line or so of the error message. Try adding your operating system to the search query if needed.

If you have trouble installing the requirements, you can skip that step, except on Python 2, where you must `pip install mock`. See *Running all the tests* for details on installing the optional test dependencies. If you don't have an optional dependency installed, the tests that require it will be skipped.

Running the tests requires a Django settings module that defines the databases to use. To make it easy to get started, Django provides and uses a sample settings module that uses the SQLite database. See *Using another settings module* to learn how to use a different settings module to run the tests with a different database.

---

### Windows users

We recommend something like [Git Bash](#) to run the tests using the above approach.

---

Having problems? See *Troubleshooting* for some common issues.

### Using another settings module

The included settings module (`tests/test_sqlite.py`) allows you to run the test suite using SQLite. If you want to run the tests using a different database, you'll need to define your own settings file. Some tests, such as those for `contrib.postgres`, are specific to a particular database backend and will be skipped if run with a different backend.

To run the tests with different settings, ensure that the module is on your `PYTHONPATH` and pass the module with `--settings`.

The `DATABASES` setting in any test settings module needs to define two databases:

- A default database. This database should use the backend that you want to use for primary testing.
- A database with the alias `other`. The `other` database is used to test that queries can be directed to different databases. This database should use the same backend as the `default`, and it must have a different name.

If you're using a backend that isn't SQLite, you will need to provide other details for each database:

- The `USER` option needs to specify an existing user account for the database. That user needs permission to execute `CREATE DATABASE` so that the test database can be created.
- The `PASSWORD` option needs to provide the password for the `USER` that has been specified.

Test databases get their names by prepending `test_` to the value of the `NAME` settings for the databases defined in `DATABASES`. These test databases are deleted when the tests are finished.

You will also need to ensure that your database uses UTF-8 as the default character set. If your database server doesn't use UTF-8 as a default charset, you will need to include a value for `CHARSET` in the test settings dictionary for the applicable database.

## Running only some of the tests

Django's entire test suite takes a while to run, and running every single test could be redundant if, say, you just added a test to Django that you want to run quickly without running everything else. You can run a subset of the unit tests by appending the names of the test modules to `runtests.py` on the command line.

For example, if you'd like to run tests only for generic relations and internationalization, type:

```
$ ./runtests.py --settings=path.to.settings generic_relations i18n
```

How do you find out the names of individual tests? Look in `tests/` — each directory name there is the name of a test.

If you just want to run a particular class of tests, you can specify a list of paths to individual test classes. For example, to run the `TranslationTests` of the `i18n` module, type:

```
$ ./runtests.py --settings=path.to.settings i18n.tests.TranslationTests
```

Going beyond that, you can specify an individual test method like this:

```
$ ./runtests.py --settings=path.to.settings i18n.tests.TranslationTests.test_lazy_
↳objects
```

## Running the Selenium tests

Some tests require Selenium and a Web browser. To run these tests, you must install the `selenium` package and run the tests with the `--selenium=<BROWSERS>` option. For example, if you have Firefox and Google Chrome installed:

```
$ ./runtests.py --selenium=firefox,chrome
```

See the `selenium.webdriver` package for the list of available browsers.

Specifying `--selenium` automatically sets `--tags=selenium` to run only the tests that require selenium.

## Running all the tests

If you want to run the full suite of tests, you'll need to install a number of dependencies:

- `argon2-cffi` 16.1.0+
- `bcrypt`
- `docutils`
- `enum34` (Python 2 only)
- `geoip2`
- `jinjja2` 2.7+

- `numpy`
- `Pillow`
- `PyYAML`
- `pytz`
- `setuptools`
- `memcached`, plus a *supported Python binding*
- `mock` (for Python 2)
- `gettext` (*gettext on Windows*)
- `selenium`
- `sqlparse`

You can find these dependencies in `pip requirements` files inside the `tests/requirements` directory of the Django source tree and install them like so:

```
$ pip install -r tests/requirements/py3.txt # Python 2: py2.txt
```

If you encounter an error during the installation, your system might be missing a dependency for one or more of the Python packages. Consult the failing package’s documentation or search the Web with the error message that you encounter.

You can also install the database adapter(s) of your choice using `oracle.txt`, `mysql.txt`, or `postgres.txt`.

If you want to test the memcached cache backend, you’ll also need to define a `CACHES` setting that points at your memcached instance.

To run the GeoDjango tests, you will need to *setup a spatial database and install the Geospatial libraries*.

Each of these dependencies is optional. If you’re missing any of them, the associated tests will be skipped.

## Code coverage

Contributors are encouraged to run coverage on the test suite to identify areas that need additional tests. The coverage tool installation and use is described in *testing code coverage*.

Coverage should be run in a single process to obtain accurate statistics. To run coverage on the Django test suite using the standard test settings:

```
$ coverage run ./runtests.py --settings=test_sqlite --parallel=1
```

After running coverage, generate the html report by running:

```
$ coverage html
```

When running coverage for the Django tests, the included `.coveragerc` settings file defines `coverage_html` as the output directory for the report and also excludes several directories not relevant to the results (test code or external code included in Django).

## Contrib apps

Tests for contrib apps can be found in the `tests/` directory, typically under `<app_name>_tests`. For example, tests for `contrib.auth` are located in `tests/auth_tests`.

## Troubleshooting

### Many test failures with `UnicodeEncodeError`

If the `locales` package is not installed, some tests will fail with a `UnicodeEncodeError`.

You can resolve this on Debian-based systems, for example, by running:

```
$ apt-get install locales
$ dpkg-reconfigure locales
```

You can resolve this for macOS systems by configuring your shell's locale:

```
$ export LANG="en_US.UTF-8"
$ export LC_ALL="en_US.UTF-8"
```

Run the `locale` command to confirm the change. Optionally, add those export commands to your shell's startup file (e.g. `~/ .bashrc` for Bash) to avoid having to retype them.

### Tests that only fail in combination

In case a test passes when run in isolation but fails within the whole suite, we have some tools to help analyze the problem.

The `--bisect` option of `runtests.py` will run the failing test while halving the test set it is run together with on each iteration, often making it possible to identify a small number of tests that may be related to the failure.

For example, suppose that the failing test that works on its own is `ModelTest.test_eq`, then using:

```
$ ./runtests.py --bisect basic.tests.ModelTest.test_eq
```

will try to determine a test that interferes with the given one. First, the test is run with the first half of the test suite. If a failure occurs, the first half of the test suite is split in two groups and each group is then run with the specified test. If there is no failure with the first half of the test suite, the second half of the test suite is run with the specified test and split appropriately as described earlier. The process repeats until the set of failing tests is minimized.

The `--pair` option runs the given test alongside every other test from the suite, letting you check if another test has side-effects that cause the failure. So:

```
$ ./runtests.py --pair basic.tests.ModelTest.test_eq
```

will pair `test_eq` with every test label.

With both `--bisect` and `--pair`, if you already suspect which cases might be responsible for the failure, you may limit tests to be cross-analyzed by *specifying further test labels* after the first one:

```
$ ./runtests.py --pair basic.tests.ModelTest.test_eq queries transactions
```

You can also try running any set of tests in reverse using the `--reverse` option in order to verify that executing tests in a different order does not cause any trouble:

```
$ ./runtests.py basic --reverse
```

## Seeing the SQL queries run during a test

If you wish to examine the SQL being run in failing tests, you can turn on *SQL logging* using the `--debug-sql` option. If you combine this with `--verbosity=2`, all SQL queries will be output:

```
$ ./runtests.py basic --debug-sql
```

## Seeing the full traceback of a test failure

By default tests are run in parallel with one process per core. When the tests are run in parallel, however, you'll only see a truncated traceback for any test failures. You can adjust this behavior with the `--parallel` option:

```
$ ./runtests.py basic --parallel=1
```

You can also use the `DJANGO_TEST_PROCESSES` environment variable for this purpose.

Support for running tests in parallel and the `--parallel` option were added.

## Tips for writing tests

### Isolating model registration

To avoid polluting the global `apps` registry and prevent unnecessary table creation, models defined in a test method should be bound to a temporary `Apps` instance:

```
from django.apps.registry import Apps
from django.db import models
from django.test import SimpleTestCase

class TestModelDefinition(SimpleTestCase):
    def test_model_definition(self):
        test_apps = Apps(['app_label'])

        class TestModel(models.Model):
            class Meta:
                apps = test_apps
        ...
```

```
django.test.utils.isolate_apps(*app_labels, attr_name=None, kwarg_name=None)
```

Since this pattern involves a lot of boilerplate, Django provides the `isolate_apps()` decorator. It's used like this:

```
from django.db import models
from django.test import SimpleTestCase
from django.test.utils import isolate_apps

class TestModelDefinition(SimpleTestCase):
    @isolate_apps('app_label')
    def test_model_definition(self):
        class TestModel(models.Model):
            pass
        ...
```

---

### Setting `app_label`

Models defined in a test method with no explicit `app_label` are automatically assigned the label of the app in which their test class is located.

In order to make sure the models defined within the context of `isolate_apps()` instances are correctly installed, you should pass the set of targeted `app_label` as arguments:

```
tests/app_label/tests.py

from django.db import models
from django.test import SimpleTestCase
from django.test.utils import isolate_apps

class TestModelDefinition(SimpleTestCase):
    @isolate_apps('app_label', 'other_app_label')
    def test_model_definition(self):
        # This model automatically receives app_label='app_label'
        class TestModel(models.Model):
            pass

        class OtherAppModel(models.Model):
            class Meta:
                app_label = 'other_app_label'

        ...
```

The decorator can also be applied to classes:

```
from django.db import models
from django.test import SimpleTestCase
from django.test.utils import isolate_apps

@isolate_apps('app_label')
class TestModelDefinition(SimpleTestCase):
    def test_model_definition(self):
        class TestModel(models.Model):
            pass

        ...
```

The temporary `Apps` instance used to isolate model registration can be retrieved as an attribute when used as a class decorator by using the `attr_name` parameter:

```
from django.db import models
from django.test import SimpleTestCase
from django.test.utils import isolate_apps

@isolate_apps('app_label', attr_name='apps')
class TestModelDefinition(SimpleTestCase):
    def test_model_definition(self):
        class TestModel(models.Model):
            pass

        self.assertIs(self.apps.get_model('app_label', 'TestModel'), TestModel)
```

Or as an argument on the test method when used as a method decorator by using the `kwarg_name` parameter:

```
from django.db import models
from django.test import SimpleTestCase
from django.test.utils import isolate_apps

class TestModelDefinition(SimpleTestCase):
    @isolate_apps('app_label', kwarg_name='apps')
```

```
def test_model_definition(self, apps):
    class TestModel(models.Model):
        pass
    self.assertIs(apps.get_model('app_label', 'TestModel'), TestModel)
```

## Submitting patches

We're always grateful for patches to Django's code. Indeed, bug reports with associated patches will get fixed *far* more quickly than those without patches.

## Typo fixes and trivial documentation changes

If you are fixing a really trivial issue, for example changing a word in the documentation, the preferred way to provide the patch is using GitHub pull requests without a Trac ticket.

See the *Working with Git and GitHub* for more details on how to use pull requests.

## “Claiming” tickets

In an open-source project with hundreds of contributors around the world, it's important to manage communication efficiently so that work doesn't get duplicated and contributors can be as effective as possible.

Hence, our policy is for contributors to “claim” tickets in order to let other developers know that a particular bug or feature is being worked on.

If you have identified a contribution you want to make and you're capable of fixing it (as measured by your coding ability, knowledge of Django internals and time availability), claim it by following these steps:

- [Login using your GitHub account](#) or [create an account](#) in our ticket system. If you have an account but have forgotten your password, you can reset it using the [password reset page](#).
- If a ticket for this issue doesn't exist yet, create one in our [ticket tracker](#).
- If a ticket for this issue already exists, make sure nobody else has claimed it. To do this, look at the “Owned by” section of the ticket. If it's assigned to “nobody,” then it's available to be claimed. Otherwise, somebody else may be working on this ticket. Either find another bug/feature to work on, or contact the developer working on the ticket to offer your help. If a ticket has been assigned for weeks or months without any activity, it's probably safe to reassign it to yourself.
- Log into your account, if you haven't already, by clicking “GitHub Login” or “DjangoProject Login” in the upper left of the ticket page.
- Claim the ticket by clicking the “assign to myself” radio button under “Action” near the bottom of the page, then click “Submit changes.”

---

**Note:** The Django software foundation requests that anyone contributing more than a trivial patch to Django sign and submit a [Contributor License Agreement](#), this ensures that the Django Software Foundation has clear license to all contributions allowing for a clear license for all users.

---

## Ticket claimers' responsibility

Once you've claimed a ticket, you have a responsibility to work on that ticket in a reasonably timely fashion. If you don't have time to work on it, either unclaim it or don't claim it in the first place!

If there's no sign of progress on a particular claimed ticket for a week or two, another developer may ask you to relinquish the ticket claim so that it's no longer monopolized and somebody else can claim it.

If you've claimed a ticket and it's taking a long time (days or weeks) to code, keep everybody updated by posting comments on the ticket. If you don't provide regular updates, and you don't respond to a request for a progress report, your claim on the ticket may be revoked.

As always, more communication is better than less communication!

## Which tickets should be claimed?

Of course, going through the steps of claiming tickets is overkill in some cases.

In the case of small changes, such as typos in the documentation or small bugs that will only take a few minutes to fix, you don't need to jump through the hoops of claiming tickets. Just submit your patch and be done with it.

Of course, it is *always* acceptable, regardless whether someone has claimed it or not, to submit patches to a ticket if you happen to have a patch ready.

## Patch style

Make sure that any contribution you do fulfills at least the following requirements:

- The code required to fix a problem or add a feature is an essential part of a patch, but it is not the only part. A good patch should also include a *regression test* to validate the behavior that has been fixed and to prevent the problem from arising again. Also, if some tickets are relevant to the code that you've written, mention the ticket numbers in some comments in the test so that one can easily trace back the relevant discussions after your patch gets committed, and the tickets get closed.
- If the code associated with a patch adds a new feature, or modifies behavior of an existing feature, the patch should also contain documentation.

When you think your work is ready to be reviewed, send *a GitHub pull request*. Please review the patch yourself using our *patch review checklist* first.

If you can't send a pull request for some reason, you can also use patches in Trac. When using this style, follow these guidelines.

- Submit patches in the format returned by the `git diff` command.
- Attach patches to a ticket in the *ticket tracker*, using the "attach file" button. Please *don't* put the patch in the ticket description or comment unless it's a single line patch.
- Name the patch file with a `.diff` extension; this will let the ticket tracker apply correct syntax highlighting, which is quite helpful.

Regardless of the way you submit your work, follow these steps.

- Make sure your code fulfills the requirements in our *patch review checklist*.
- Check the "Has patch" box on the ticket and make sure the "Needs documentation", "Needs tests", and "Patch needs improvement" boxes aren't checked. This makes the ticket appear in the "Patches needing review" queue on the *Development dashboard*.

## Non-trivial patches

A “non-trivial” patch is one that is more than a simple bug fix. It’s a patch that introduces Django functionality and makes some sort of design decision.

If you provide a non-trivial patch, include evidence that alternatives have been discussed on [django-developers](#).

If you’re not sure whether your patch should be considered non-trivial, just ask.

## Deprecating a feature

There are a couple reasons that code in Django might be deprecated:

- If a feature has been improved or modified in a backwards-incompatible way, the old feature or behavior will be deprecated.
- Sometimes Django will include a backport of a Python library that’s not included in a version of Python that Django currently supports. When Django no longer needs to support the older version of Python that doesn’t include the library, the library will be deprecated in Django.

As the [deprecation policy](#) describes, the first release of Django that deprecates a feature (A.B) should raise a `RemovedInDjangoXXWarning` (where XX is the Django version where the feature will be removed) when the deprecated feature is invoked. Assuming we have good test coverage, these warnings are converted to errors when [running the test suite](#) with warnings enabled: `python -Wall runtests.py`. Thus, when adding a `RemovedInDjangoXXWarning` you need to eliminate or silence any warnings generated when running the tests.

The first step is to remove any use of the deprecated behavior by Django itself. Next you can silence warnings in tests that actually test the deprecated behavior by using the `ignore_warnings` decorator, either at the test or class level:

1. In a particular test:

```
from django.test import ignore_warnings
from django.utils.deprecation import RemovedInDjangoXXWarning

@ignore_warnings(category=RemovedInDjangoXXWarning)
def test_foo(self):
    ...
```

2. For an entire test case:

```
from django.test import ignore_warnings
from django.utils.deprecation import RemovedInDjangoXXWarning

@ignore_warnings(category=RemovedInDjangoXXWarning)
class MyDeprecatedTests(unittest.TestCase):
    ...
```

You can also add a test for the deprecation warning. You’ll have to disable the “warning as error” behavior in your test by doing:

```
import warnings

def test_foo_deprecation_warning(self):
    with warnings.catch_warnings(record=True) as warns:
        warnings.simplefilter('always') # prevent warnings from appearing as errors
        # invoke deprecated behavior

    self.assertEqual(len(warns), 1)
```

```
msg = str(warns[0].message)
self.assertEqual(msg, 'Expected deprecation message')
```

Finally, there are a couple of updates to Django’s documentation to make:

1. If the existing feature is documented, mark it deprecated in documentation using the `.. deprecated:: A.B` annotation. Include a short description and a note about the upgrade path if applicable.
2. Add a description of the deprecated behavior, and the upgrade path if applicable, to the current release notes (`docs/releases/A.B.txt`) under the “Features deprecated in A.B” heading.
3. Add an entry in the deprecation timeline (`docs/internals/deprecation.txt`) under the appropriate version describing what code will be removed.

Once you have completed these steps, you are finished with the deprecation. In each *feature release*, all `RemovedInDjangoXXWarnings` matching the new version are removed.

## JavaScript patches

For information on JavaScript patches, see the *JavaScript patches* documentation.

## Patch review checklist

Use this checklist to review a pull request. If you are reviewing a pull request that is not your own and it passes all the criteria below, please set the “Triage Stage” on the corresponding Trac ticket to “Ready for checkin”. If you’ve left comments for improvement on the pull request, please tick the appropriate flags on the Trac ticket based on the results of your review: “Patch needs improvement”, “Needs documentation”, and/or “Needs tests”. As time and interest permits, core developers do final reviews of “Ready for checkin” tickets and will either commit the patch or bump it back to “Accepted” if further works need to be done. If you’re looking to become a core developer, doing thorough reviews of patches is a great way to earn trust.

Looking for a patch to review? Check out the “Patches needing review” section of the [Django Development Dashboard](#). Looking to get your patch reviewed? Ensure the Trac flags on the ticket are set so that the ticket appears in that queue.

## Documentation

- Does the documentation build without any errors (`make html`, or `make.bat html` on Windows, from the `docs` directory)?
- Does the documentation follow the writing style guidelines in *Writing documentation*?
- Are there any *spelling errors*?

## Bugs

- Is there a proper regression test (the test should fail before the fix is applied)?

## New Features

- Are there tests to “exercise” all of the new code?
- Is there a release note in `docs/releases/A.B.txt`?

- Is there documentation for the feature and is it *annotated appropriately* with `.. versionadded:: A.B` or `.. versionchanged:: A.B`?

### Deprecating a feature

See the *Deprecating a feature* guide.

### All code changes

- Does the *coding style* conform to our guidelines? Are there any `flake8` errors?
- If the change is backwards incompatible in any way, is there a note in the release notes (`docs/releases/A.B.txt`)?
- Is Django's test suite passing? Ask in `#django-dev` for a core dev to build the pull request against our continuous integration server.

### All tickets

- Is the pull request a single squashed commit with a message that follows our *commit message format*?
- Are you the patch author and a new contributor? Please add yourself to the `AUTHORS` file and submit a [Contributor License Agreement](#).

### Working with Git and GitHub

This section explains how the community can contribute code to Django via pull requests. If you're interested in how core developers handle them, see *Committing code*.

Below, we are going to show how to create a GitHub pull request containing the changes for Trac ticket `#xxxxx`. By creating a fully-ready pull request, you will make the reviewer's job easier, meaning that your work is more likely to be merged into Django.

You could also upload a traditional patch to Trac, but it's less practical for reviews.

### Installing Git

Django uses [Git](#) for its source control. You can [download](#) Git, but it's often easier to install with your operating system's package manager.

Django's [Git repository](#) is hosted on [GitHub](#), and it is recommended that you also work using GitHub.

After installing Git, the first thing you should do is setup your name and email:

```
$ git config --global user.name "Your Real Name"
$ git config --global user.email "you@email.com"
```

Note that `user.name` should be your real name, not your GitHub nick. GitHub should know the email you use in the `user.email` field, as this will be used to associate your commits with your GitHub account.

## Setting up local repository

When you have created your GitHub account, with the nick “GitHub\_nick”, and forked Django’s repository, create a local copy of your fork:

```
git clone git@github.com:GitHub_nick/django.git
```

This will create a new directory “django”, containing a clone of your GitHub repository. The rest of the git commands on this page need to be run within the cloned directory, so switch to it now:

```
cd django
```

Your GitHub repository will be called “origin” in Git.

You should also setup django/django as an “upstream” remote (that is, tell git that the reference Django repository was the source of your fork of it):

```
git remote add upstream git@github.com:django/django.git
git fetch upstream
```

You can add other remotes similarly, for example:

```
git remote add akaariai git@github.com:akaariai/django.git
```

## Working on a ticket

When working on a ticket, create a new branch for the work, and base that work on upstream/master:

```
git checkout -b ticket_XXXXX upstream/master
```

The -b flag creates a new branch for you locally. Don’t hesitate to create new branches even for the smallest things - that’s what they are there for.

If instead you were working for a fix on the 1.4 branch, you would do:

```
git checkout -b ticket_XXXXX_1_4 upstream/stable/1.4.x
```

Assume the work is carried on the ticket\_XXXXX branch. Make some changes and commit them:

```
git commit
```

When writing the commit message, follow the [commit message guidelines](#) to ease the work of the committer. If you’re uncomfortable with English, try at least to describe precisely what the commit does.

If you need to do additional work on your branch, commit as often as necessary:

```
git commit -m 'Added two more tests for edge cases'
```

## Publishing work

You can publish your work on GitHub just by doing:

```
git push origin ticket_XXXXX
```

When you go to your GitHub page, you will notice a new branch has been created.

If you are working on a Trac ticket, you should mention in the ticket that your work is available from branch `ticket_xxxxx` of your GitHub repo. Include a link to your branch.

Note that the above branch is called a “topic branch” in Git parlance. You are free to rewrite the history of this branch, by using `git rebase` for example. Other people shouldn’t base their work on such a branch, because their clone would become corrupt when you edit commits.

There are also “public branches”. These are branches other people are supposed to fork, so the history of these branches should never change. Good examples of public branches are the `master` and `stable/A.B.x` branches in the `django/django` repository.

When you think your work is ready to be pulled into Django, you should create a pull request at GitHub. A good pull request means:

- commits with one logical change in each, following the *coding style*,
- well-formed messages for each commit: a summary line and then paragraphs wrapped at 72 characters thereafter – see the *committing guidelines* for more details,
- documentation and tests, if needed – actually tests are always needed, except for documentation changes.

The test suite must pass and the documentation must build without warnings.

Once you have created your pull request, you should add a comment in the related Trac ticket explaining what you’ve done. In particular, you should note the environment in which you ran the tests, for instance: “all tests pass under SQLite and MySQL”.

Pull requests at GitHub have only two states: open and closed. The committer who will deal with your pull request has only two options: merge it or close it. For this reason, it isn’t useful to make a pull request until the code is ready for merging – or sufficiently close that a committer will finish it himself.

### Rebasing branches

In the example above, you created two commits, the “Fixed ticket\_xxxxx” commit and “Added two more tests” commit.

We do not want to have the entire history of your working process in your repository. Your commit “Added two more tests” would be unhelpful noise. Instead, we would rather only have one commit containing all your work.

To rework the history of your branch you can squash the commits into one by using interactive rebase:

```
git rebase -i HEAD~2
```

The `HEAD~2` above is shorthand for two latest commits. The above command will open an editor showing the two commits, prefixed with the word “pick”.

Change “pick” on the second line to “squash” instead. This will keep the first commit, and squash the second commit into the first one. Save and quit the editor. A second editor window should open, so you can reword the commit message for the commit now that it includes both your steps.

You can also use the “edit” option in rebase. This way you can change a single commit, for example to fix a typo in a docstring:

```
git rebase -i HEAD~3
# Choose edit, pick, pick for the commits
# Now you are able to rework the commit (use git add normally to add changes)
# When finished, commit work with "--amend" and continue
git commit --amend
# Reword the commit message if needed
```

```
git rebase --continue
# The second and third commits should be applied.
```

If your topic branch is already published at GitHub, for example if you're making minor changes to take into account a review, you will need to force-push the changes:

```
git push -f origin ticket_XXXXX
```

Note that this will rewrite history of ticket\_XXXXX - if you check the commit hashes before and after the operation at GitHub you will notice that the commit hashes do not match anymore. This is acceptable, as the branch is merely a topic branch, and nobody should be basing their work on it.

## After upstream has changed

When upstream (django/django) has changed, you should rebase your work. To do this, use:

```
git fetch upstream
git rebase
```

The work is automatically rebased using the branch you forked on, in the example case using `upstream/master`.

The rebase command removes all your local commits temporarily, applies the upstream commits, and then applies your local commits again on the work.

If there are merge conflicts, you will need to resolve them and then use `git rebase --continue`. At any point you can use `git rebase --abort` to return to the original state.

Note that you want to *rebase* on upstream, not *merge* the upstream.

The reason for this is that by rebasing, your commits will always be *on top of* the upstream's work, not *mixed in with* the changes in the upstream. This way your branch will contain only commits related to its topic, which makes squashing easier.

## After review

It is unusual to get any non-trivial amount of code into core without changes requested by reviewers. In this case, it is often a good idea to add the changes as one incremental commit to your work. This allows the reviewer to easily check what changes you have done.

In this case, do the changes required by the reviewer. Commit as often as necessary. Before publishing the changes, rebase your work. If you added two commits, you would run:

```
git rebase -i HEAD~2
```

Squash the second commit into the first. Write a commit message along the lines of:

```
Made changes asked in review by <reviewer>

- Fixed whitespace errors in foobar
- Reworded the docstring of bar()
```

Finally, push your work back to your GitHub repository. Since you didn't touch the public commits during the rebase, you should not need to force-push:

```
git push origin ticket_XXXXX
```

Your pull request should now contain the new commit too.

Note that the committer is likely to squash the review commit into the previous commit when committing the code.

### Working on a patch

One of the ways that developers can contribute to Django is by reviewing patches. Those patches will typically exist as pull requests on GitHub and can be easily integrated into your local repository:

```
git checkout -b pull_XXXXX upstream/master
curl https://github.com/django/django/pull/XXXXX.patch | git am
```

This will create a new branch and then apply the changes from the pull request to it. At this point you can run the tests or do anything else you need to do to investigate the quality of the patch.

For more detail on working with pull requests see the *guidelines for committers*.

### Summary

- Work on GitHub if you can.
- Announce your work on the Trac ticket by linking to your GitHub branch.
- When you have something ready, make a pull request.
- Make your pull requests as good as you can.
- When doing fixes to your work, use `git rebase -i` to squash the commits.
- When upstream has changed, do `git fetch upstream; git rebase`.

### JavaScript

While most of Django core is Python, the `admin` and `gis` contrib apps contain JavaScript code.

Please follow these coding standards when writing JavaScript code for inclusion in Django.

### Code style

- Please conform to the indentation style dictated in the `.editorconfig` file. We recommend using a text editor with `EditorConfig` support to avoid indentation and whitespace issues. Most of the JavaScript files use 4 spaces for indentation, but there are some exceptions.
- When naming variables, use `camelCase` instead of `underscore_case`. Different JavaScript files sometimes use a different code style. Please try to conform to the code style of each file.
- Use the `JSHint` code linter to check your code for bugs and style errors. `JSHint` will be run when you run the JavaScript tests. We also recommended installing a `JSHint` plugin in your text editor.

### JavaScript patches

Django’s admin system leverages the jQuery framework to increase the capabilities of the admin interface. In conjunction, there is an emphasis on admin JavaScript performance and minimizing overall admin media file size. Serving compressed or “minified” versions of JavaScript files is considered best practice in this regard.

To that end, patches for JavaScript files should include both the original code for future development (e.g. `foo.js`), and a compressed version for production use (e.g. `foo.min.js`). Any links to the file in the codebase should point to the compressed version.

## Compressing JavaScript

To simplify the process of providing optimized JavaScript code, Django includes a handy Python script which should be used to create a “minified” version. To run it:

```
$ pip install closure
$ python django/contrib/admin/bin/compress.py
```

Behind the scenes, `compress.py` is a front-end for Google’s [Closure Compiler](#) which is written in Java. The Closure Compiler library is not bundled with Django, but you can install it using `pip` as done above. The Closure Compiler library requires [Java 7](#) or higher.

Please don’t forget to run `compress.py` and include the `diff` of the minified scripts when submitting patches for Django’s JavaScript.

## JavaScript tests

Django’s JavaScript tests can be run in a browser or from the command line. The tests are located in a top level `js_tests` directory.

## Writing tests

Django’s JavaScript tests use [QUnit](#). Here is an example test module:

```
module('magicTricks', {
  beforeEach: function() {
    var $ = django.jQuery;
    $('#qunit-fixture').append('<button class="button"></button>');
  }
});

test('removeOnClick removes button on click', function(assert) {
  var $ = django.jQuery;
  removeOnClick('.button');
  assert.equal($('.button').length === 1);
  $('.button').click();
  assert.equal($('.button').length === 0);
});

test('copyOnClick adds button on click', function(assert) {
  var $ = django.jQuery;
  copyOnClick('.button');
  assert.equal($('.button').length === 1);
  $('.button').click();
  assert.equal($('.button').length === 2);
});
```

Please consult the [QUnit](#) documentation for information on the types of assertions supported by QUnit.

## Running tests

The JavaScript tests may be run from a web browser or from the command line.

### Testing from a web browser

To run the tests from a web browser, open up `js_tests/tests.html` in your browser.

To measure code coverage when running the tests, you need to view that file over HTTP. To view code coverage:

- Execute `python -m http.server` (or `python -m SimpleHTTPServer` on Python 2) from the root directory (not from inside `js_tests`).
- Open `http://localhost:8000/js_tests/tests.html` in your web browser.

### Testing from the command line

To run the tests from the command line, you need to have `Node.js` installed.

After installing `Node.js`, install the JavaScript test dependencies by running the following from the root of your Django checkout:

```
$ npm install
```

Then run the tests with:

```
$ npm test
```

## 10.1.5 Writing documentation

We place a high importance on consistency and readability of documentation. After all, Django was created in a journalism environment! So we treat our documentation like we treat our code: we aim to improve it as often as possible.

Documentation changes generally come in two forms:

- General improvements: typo corrections, error fixes and better explanations through clearer writing and more examples.
- New features: documentation of features that have been added to the framework since the last release.

This section explains how writers can craft their documentation changes in the most useful and least error-prone ways.

### Getting the raw documentation

Though Django's documentation is intended to be read as HTML at <https://docs.djangoproject.com/>, we edit it as a collection of text files for maximum flexibility. These files live in the top-level `docs/` directory of a Django release.

If you'd like to start contributing to our docs, get the development version of Django from the source code repository (see *Installing the development version*). The development version has the latest-and-greatest documentation, just as it has latest-and-greatest code. We also backport documentation fixes and improvements, at the discretion of the committer, to the last release branch. That's because it's highly advantageous to have the docs for the last release be up-to-date and correct (see *Differences between versions*).

## Getting started with Sphinx

Django’s documentation uses the [Sphinx](#) documentation system, which in turn is based on [docutils](#). The basic idea is that lightly-formatted plain-text documentation is transformed into HTML, PDF, and any other output format.

To actually build the documentation locally, you’ll currently need to install Sphinx – `pip install Sphinx` should do the trick.

Then, building the HTML is easy; just make `html` (or `make.bat html` on Windows) from the `docs` directory.

To get started contributing, you’ll want to read the [reStructuredText Primer](#). After that, you’ll want to read about the [Sphinx-specific markup](#) that’s used to manage metadata, indexing, and cross-references.

## How the documentation is organized

The documentation is organized into several categories:

- *Tutorials* take the reader by the hand through a series of steps to create something.

The important thing in a tutorial is to help the reader achieve something useful, preferably as early as possible, in order to give them confidence.

Explain the nature of the problem we’re solving, so that the reader understands what we’re trying to achieve. Don’t feel that you need to begin with explanations of how things work - what matters is what the reader does, not what you explain. It can be helpful to refer back to what you’ve done and explain afterwards.

- *Topic guides* aim to explain a concept or subject at a fairly high level.

Link to reference material rather than repeat it. Use examples and don’t be reluctant to explain things that seem very basic to you - it might be the explanation someone else needs.

Providing background context helps a newcomer connect the topic to things that they already know.

- *Reference guides* contain technical reference for APIs. They describe the functioning of Django’s internal machinery and instruct in its use.

Keep reference material tightly focused on the subject. Assume that the reader already understands the basic concepts involved but needs to know or be reminded of how Django does it.

Reference guides aren’t the place for general explanation. If you find yourself explaining basic concepts, you may want to move that material to a topic guide.

- *How-to guides* are recipes that take the reader through steps in key subjects.

What matters most in a how-to guide is what a user wants to achieve. A how-to should always be result-oriented rather than focused on internal details of how Django implements whatever is being discussed.

These guides are more advanced than tutorials and assume some knowledge about how Django works. Assume that the reader has followed the tutorials and don’t hesitate to refer the reader back to the appropriate tutorial rather than repeat the same material.

## Writing style

When using pronouns in reference to a hypothetical person, such as “a user with a session cookie”, gender neutral pronouns (they/their/them) should be used. Instead of:

- he or she... use they.
- him or her... use them.
- his or her... use their.

- his or hers... use theirs.
- himself or herself... use themselves.

## Commonly used terms

Here are some style guidelines on commonly used terms throughout the documentation:

- **Django** – when referring to the framework, capitalize Django. It is lowercase only in Python code and in the `django` project.com logo.
- **email** – no hyphen.
- **MySQL, PostgreSQL, SQLite**
- **SQL** – when referring to SQL, the expected pronunciation should be “Ess Queue Ell” and not “sequel”. Thus in a phrase like “Returns an SQL expression”, “SQL” should be preceded by “an” and not “a”.
- **Python** – when referring to the language, capitalize Python.
- **realize, customize, initialize**, etc. – use the American “ize” suffix, not “ise.”
- **subclass** – it’s a single word without a hyphen, both as a verb (“subclass that model”) and as a noun (“create a subclass”).
- **Web, World Wide Web, the Web** – note Web is always capitalized when referring to the World Wide Web.
- **website** – use one word, without capitalization.

## Django-specific terminology

- **model** – it’s not capitalized.
- **template** – it’s not capitalized.
- **URLconf** – use three capitalized letters, with no space before “conf.”
- **view** – it’s not capitalized.

## Guidelines for reStructuredText files

These guidelines regulate the format of our reST (reStructuredText) documentation:

- In section titles, capitalize only initial words and proper nouns.
- Wrap the documentation at 80 characters wide, unless a code example is significantly less readable when split over two lines, or for another good reason.
- The main thing to keep in mind as you write and edit docs is that the more semantic markup you can add the better. So:

```
Add ``django.contrib.auth`` to your ``INSTALLED_APPS``...
```

Isn’t nearly as helpful as:

```
Add :mod:`~django.contrib.auth` to your :setting:`INSTALLED_APPS`...
```

This is because Sphinx will generate proper links for the latter, which greatly helps readers.

You can prefix the target with a `~` (that’s a tilde) to get just the “last bit” of that path. So `:mod:`~django.contrib.auth`` will just display a link with the title “auth”.

- Use `intersphinx` to reference Python’s and Sphinx’ documentation.
- Add `.. code-block:: <lang>` to literal blocks so that they get highlighted. Prefer relying on automatic highlighting simply using `::` (two colons). This has the benefit that if the code contains some invalid syntax, it won’t be highlighted. Adding `.. code-block:: python`, for example, will force highlighting despite invalid syntax.
- Use these heading styles:

```

===
One
===

Two
===

Three
-----

Four
~~~~~

Five
^^^^

```

## Django-specific markup

Besides the [Sphinx built-in markup](#), Django’s docs defines some extra description units:

- Settings:

```
.. setting:: INSTALLED_APPS
```

To link to a setting, use `:setting:`INSTALLED_APPS``.

- Template tags:

```
.. templatetag:: regroup
```

To link, use `:ttag:`regroup``.

- Template filters:

```
.. templatefilter:: linebreaksbr
```

To link, use `:tfilter:`linebreaksbr``.

- Field lookups (i.e. `Foo.objects.filter(bar__exact=whatever)`):

```
.. fieldlookup:: exact
```

To link, use `:lookup:`exact``.

- `django-admin` commands:

```
.. django-admin:: migrate
```

To link, use `:dadmin:`migrate``.

- django-admin command-line options:

```
.. django-admin-option:: --traceback
```

To link, use `:option:`command_name --traceback`` (or omit `command_name` for the options shared by all commands like `--verbosity`).

- Links to Trac tickets (typically reserved for patch release notes):

```
:ticket:`12345`
```

## Documenting new features

Our policy for new features is:

All documentation of new features should be written in a way that clearly designates the features are only available in the Django development version. Assume documentation readers are using the latest release, not the development version.

Our preferred way for marking new features is by prefacing the features' documentation with: `.. versionadded:: X.Y`, followed by a mandatory blank line and an optional description (indented).

General improvements, or other changes to the APIs that should be emphasized should use the `.. versionchanged:: X.Y` directive (with the same format as the `versionadded` mentioned above).

These `versionadded` and `versionchanged` blocks should be “self-contained.” In other words, since we only keep these annotations around for two releases, it's nice to be able to remove the annotation and its contents without having to reflow, reindent, or edit the surrounding text. For example, instead of putting the entire description of a new or changed feature in a block, do something like this:

```
.. class:: Author(first_name, last_name, middle_name=None)

    A person who writes books.

    ``first_name`` is ...

    ...

    ``middle_name`` is ...

    .. versionchanged:: A.B

        The ``middle_name`` argument was added.
```

Put the changed annotation notes at the bottom of a section, not the top.

Also, avoid referring to a specific version of Django outside a `versionadded` or `versionchanged` block. Even inside a block, it's often redundant to do so as these annotations render as “New in Django A.B:” and “Changed in Django A.B”, respectively.

If a function, attribute, etc. is added, it's also okay to use a `versionadded` annotation like this:

```
.. attribute:: Author.middle_name

    .. versionadded:: A.B

    An author's middle name.
```

We can simply remove the `.. versionadded:: A.B` annotation without any indentation changes when the time comes.

## Minimizing images

Optimize image compression where possible. For PNG files, use OptiPNG and AdvanceCOMP's `advpng`:

```
$ cd docs/
$ optipng -o7 -zml-9 -i0 -strip all `find . -type f -not -path "./_build/*" -name "*.
↪png"`
$ advpng -z4 `find . -type f -not -path "./_build/*" -name "*.png"`
```

This is based on OptiPNG version 0.7.5. Older versions may complain about the `--strip all` option being lossy.

## An example

For a quick example of how it all fits together, consider this hypothetical example:

- First, the `ref/settings.txt` document could have an overall layout like this:

```
=====
Settings
=====

...

.. _available-settings:

Available settings
=====

...

.. _deprecated-settings:

Deprecated settings
=====

...
```

- Next, the `topics/settings.txt` document could contain something like this:

```
You can access a :ref:`listing of all available settings
<available-settings>`. For a list of deprecated settings see
:ref:`deprecated-settings`.

You can find both in the :doc:`settings reference document
</ref/settings>`.
```

We use the Sphinx `doc` cross reference element when we want to link to another document as a whole and the `ref` element when we want to link to an arbitrary location in a document.

- Next, notice how the settings are annotated:

```
.. setting:: ADMINS

ADMINS
```

```
=====  
  
Default: ``[]`` (Empty list)  
  
A list of all the people who get code error notifications. When  
``DEBUG=False`` and a view raises an exception, Django will email these people  
with the full exception information. Each member of the list should be a tuple  
of (Full name, email address). Example::  
  
    [('John', 'john@example.com'), ('Mary', 'mary@example.com')]  
  
Note that Django will email all of these people whenever an error happens.  
See :doc:`/howto/error-reporting` for more information.
```

This marks up the following header as the “canonical” target for the setting `ADMINS`. This means any time I talk about `ADMINS`, I can reference it using `:setting:`ADMINS``.

That’s basically how everything fits together.

## Spelling check

Before you commit your docs, it’s a good idea to run the spelling checker. You’ll need to install a couple packages first:

- `pyenchant` (which requires `enchant`)
- `sphinxcontrib-spelling`

Then from the `docs` directory, run `make spelling`. Wrong words (if any) along with the file and line number where they occur will be saved to `_build/spelling/output.txt`.

If you encounter false-positives (error output that actually is correct), do one of the following:

- Surround inline code or brand/technology names with grave accents (`).
- Find synonyms that the spell checker recognizes.
- If, and only if, you are sure the word you are using is correct - add it to `docs/spelling_wordlist` (please keep the list in alphabetical order).

## Translating documentation

See *Localizing the Django documentation* if you’d like to help translate the documentation into another language.

### django-admin man page

Sphinx can generate a manual page for the `django-admin` command. This is configured in `docs/conf.py`. Unlike other documentation output, this man page should be included in the Django repository and the releases as `docs/man/django-admin.1`. There isn’t a need to update this file when updating the documentation, as it’s updated once as part of the release process.

To generate an updated version of the man page, run `make man` in the `docs` directory. The new man page will be written in `docs/_build/man/django-admin.1`.

## 10.1.6 Localizing Django

Various parts of Django, such as the admin site and validation error messages, are internationalized. This means they display differently depending on each user’s language or country. For this, Django uses the same internationalization and localization infrastructure available to Django applications, described in the *i18n documentation*.

### Translations

Translations are contributed by Django users worldwide. The translation work is coordinated at [Transifex](#).

If you find an incorrect translation or want to discuss specific translations, go to the [Django project page](#). If you would like to help out with translating or add a language that isn’t yet translated, here’s what to do:

- Join the [Django i18n mailing list](#) and introduce yourself.
- Make sure you read the notes about [Specialties of Django translation](#).
- Sign up at [Transifex](#) and visit the [Django project page](#).
- On the [Django project page](#), choose the language you want to work on, **or** – in case the language doesn’t exist yet – request a new language team by clicking on the “Request language” link and selecting the appropriate language.
- Then, click the “Join this Team” button to become a member of this team. Every team has at least one coordinator who is responsible to review your membership request. You can of course also contact the team coordinator to clarify procedural problems and handle the actual translation process.
- Once you are a member of a team choose the translation resource you want to update on the team page. For example the “core” resource refers to the translation catalog that contains all non-contrib translations. Each of the contrib apps also have a resource (prefixed with “contrib”).

---

**Note:** For more information about how to use Transifex, read the [Transifex User Guide](#).

---

Translations from Transifex are only integrated into the Django repository at the time of a new *feature release*. We try to update them a second time during one of the following *patch releases*, but that depends on the translation manager’s availability. So don’t miss the string freeze period (between the release candidate and the feature release) to take the opportunity to complete and fix the translations for your language!

### Formats

You can also review `conf/locale/<locale>/formats.py`. This file describes the date, time and numbers formatting particularities of your locale. See [Format localization](#) for details.

The format files aren’t managed by the use of Transifex. To change them, you must *create a patch* against the Django source tree, as for any code change:

- Create a diff against the current Git master branch.
- Open a ticket in Django’s ticket system, set its `Component` field to `Translations`, and attach the patch to it.

### Documentation

There is also an opportunity to translate the documentation, though this is a huge undertaking to complete entirely (you have been warned!). We use the same [Transifex tool](#). The translations will appear at `https://docs`.

`djangoproject.com/<language_code>/` when at least the `docs/intro/*` files are fully translated in your language.

## 10.1.7 Committing code

This section is addressed to the *Committers* and to anyone interested in knowing how code gets committed into Django core. If you're a community member who wants to contribute code to Django, have a look at *Working with Git and GitHub* instead.

### Handling pull requests

Since Django is now hosted at GitHub, most patches are provided in the form of pull requests.

When committing a pull request, make sure each individual commit matches the commit guidelines described below. Contributors are expected to provide the best pull requests possible. In practice however, committers - who will likely be more familiar with the commit guidelines - may decide to bring a commit up to standard themselves.

---

**Note:** Before merging, but after reviewing, have Jenkins test the pull request by commenting “buildbot, test this please” on the PR. See our [Jenkins wiki page](#) for more details.

---

An easy way to checkout a pull request locally is to add an alias to your `~/.gitconfig` (upstream is assumed to be `django/django`):

```
[alias]
  pr = !sh -c \"git fetch upstream pull/${1}/head:pr/${1} && git checkout pr/${1}\"
```

Now you can simply run `git pr #####` to checkout the corresponding pull request.

At this point, you can work on the code. Use `git rebase -i` and `git commit --amend` to make sure the commits have the expected level of quality. Once you're ready:

```
$ # Pull in the latest changes from master.
$ git checkout master
$ git pull upstream master
$ # Rebase the pull request on master.
$ git checkout pr/####
$ git rebase master
$ git checkout master
$ # Merge the work as "fast-forward" to master to avoid a merge commit.
$ # (in practice, you can omit "--ff-only" since you just rebased)
$ git merge --ff-only pr/XXXX
$ # If you're not sure if you did things correctly, check that only the
$ # changes you expect will be pushed to upstream.
$ git push --dry-run upstream master
$ # Push!
$ git push upstream master
$ # Delete the pull request branch.
$ git branch -d pr/xxxx
```

For changes on your own branches, force push to your fork after rebasing on master but before merging and pushing to upstream. This allows the commit hashes on master and your branch to match which automatically closes the pull request. Since you can't push to other contributors' branches, comment on the pull request “Merged in XXXXXXXX” (replacing with the commit hash) after you merge it. Trac checks for this message format to indicate on the ticket page whether or not a pull request is merged.

Avoid using GitHub’s “Merge pull request” button on the website as it creates an ugly “merge commit” and makes navigating history more difficult.

When rewriting the commit history of a pull request, the goal is to make Django’s commit history as usable as possible:

- If a patch contains back-and-forth commits, then rewrite those into one. For example, if a commit adds some code and a second commit fixes stylistic issues introduced in the first commit, those commits should be squashed before merging.
- Separate changes to different commits by logical grouping: if you do a stylistic cleanup at the same time as you do other changes to a file, separating the changes into two different commits will make reviewing history easier.
- Beware of merges of upstream branches in the pull requests.
- Tests should pass and docs should build after each commit. Neither the tests nor the docs should emit warnings.
- Trivial and small patches usually are best done in one commit. Medium to large work may be split into multiple commits if it makes sense.

Practicality beats purity, so it is up to each committer to decide how much history mangling to do for a pull request. The main points are engaging the community, getting work done, and having a usable commit history.

## Committing guidelines

In addition, please follow the following guidelines when committing code to Django’s Git repository:

- Never change the published history of `django/django` branches by force pushing. If you absolutely must (for security reasons for example), first discuss the situation with the team.
- For any medium-to-big changes, where “medium-to-big” is according to your judgment, please bring things up on the *django-developers* mailing list before making the change.

If you bring something up on *django-developers* and nobody responds, please don’t take that to mean your idea is great and should be implemented immediately because nobody contested it. Django’s core developers don’t have a lot of time to read mailing-list discussions immediately, so you may have to wait a couple of days before getting a response.

- Write detailed commit messages in the past tense, not present tense.
  - Good: “Fixed Unicode bug in RSS API.”
  - Bad: “Fixes Unicode bug in RSS API.”
  - Bad: “Fixing Unicode bug in RSS API.”

The commit message should be in lines of 72 chars maximum. There should be a subject line, separated by a blank line and then paragraphs of 72 char lines. The limits are soft. For the subject line, shorter is better. In the body of the commit message more detail is better than less:

```
Fixed #18307 -- Added git workflow guidelines

Refactored the Django's documentation to remove mentions of SVN
specific tasks. Added guidelines of how to use Git, GitHub, and
how to use pull request together with Trac instead.
```

If the patch wasn’t a pull request, you should credit the contributors in the commit message: “Thanks A for report, B for the patch and C for the review.”

- For commits to a branch, prefix the commit message with the branch name. For example: “[1.4.x] Fixed #xxxxx – Added support for mind reading.”

- Limit commits to the most granular change that makes sense. This means, use frequent small commits rather than infrequent large commits. For example, if implementing feature X requires a small change to library Y, first commit the change to library Y, then commit feature X in a separate commit. This goes a *long way* in helping all Django core developers follow your changes.
- Separate bug fixes from feature changes. Bugfixes may need to be backported to the stable branch, according to the [backwards-compatibility policy](#).
- If your commit closes a ticket in the Django [ticket tracker](#), begin your commit message with the text “Fixed #xxxxx”, where “xxxxx” is the number of the ticket your commit fixes. Example: “Fixed #123 – Added whizbang feature.”. We’ve rigged Trac so that any commit message in that format will automatically close the referenced ticket and post a comment to it with the full commit message.

If your commit closes a ticket and is in a branch, use the branch name first, then the “Fixed #xxxxx.” For example: “[1.4.x] Fixed #123 – Added whizbang feature.”

For the curious, we’re using a [Trac plugin](#) for this.

---

**Note:** Note that the Trac integration doesn’t know anything about pull requests. So if you try to close a pull request with the phrase “closes #400” in your commit message, GitHub will close the pull request, but the Trac plugin will also close the same numbered ticket in Trac.

---

- If your commit references a ticket in the Django [ticket tracker](#) but does *not* close the ticket, include the phrase “Refs #xxxxx”, where “xxxxx” is the number of the ticket your commit references. This will automatically post a comment to the appropriate ticket.
- Write commit messages for backports using this pattern:

```
[<Django version>] Fixed <ticket> -- <description>
Backport of <revision> from <branch>.
```

For example:

```
[1.3.x] Fixed #17028 -- Changed diveintopython.org -> diveintopython.net.
Backport of 80c0cbf1c97047daed2c5b41b296bbc56fe1d7e3 from master.
```

There’s a [script on the wiki](#) to automate this.

## Reverting commits

Nobody’s perfect; mistakes will be committed.

But try very hard to ensure that mistakes don’t happen. Just because we have a reversion policy doesn’t relax your responsibility to aim for the highest quality possible. Really: double-check your work, or have it checked by another committer, **before** you commit it in the first place!

When a mistaken commit is discovered, please follow these guidelines:

- If possible, have the original author revert their own commit.
- Don’t revert another author’s changes without permission from the original author.
- Use `git revert` – this will make a reverse commit, but the original commit will still be part of the commit history.
- If the original author can’t be reached (within a reasonable amount of time – a day or so) and the problem is severe – crashing bug, major test failures, etc. – then ask for objections on the [django-developers](#) mailing list then revert if there are none.

- If the problem is small (a feature commit after feature freeze, say), wait it out.
- If there's a disagreement between the committer and the reverter-to-be then try to work it out on the *django-developers* mailing list. If an agreement can't be reached then it should be put to a vote.
- If the commit introduced a confirmed, disclosed security vulnerability then the commit may be reverted immediately without permission from anyone.
- The release branch maintainer may back out commits to the release branch without permission if the commit breaks the release branch.
- If you mistakenly push a topic branch to `django/django`, just delete it. For instance, if you did:  
`git push upstream feature_antigravity`, just do a reverse push: `git push upstream :feature_antigravity`.

## 10.2 Mailing lists

---

**Important:** Please report security issues **only** to [security@djangoproject.com](mailto:security@djangoproject.com). This is a private list only open to long-time, highly trusted Django developers, and its archives are not public. For further details, please see *our security policies*.

---

Django has several official mailing lists on Google Groups that are open to anyone.

### 10.2.1 django-users

This is the right place if you are looking to ask any question regarding the installation, usage, or debugging of Django.

**Note:** If it's the first time you send an email to this list, your email must be accepted first so don't worry if *your message does not appear* instantly.

---

- [django-users mailing archive](#)
- [django-users subscription email address](#)
- [django-users posting email](#)

### 10.2.2 django-core-mentorship

The Django Core Mentorship list is intended to provide a welcoming introductory environment for community members interested in contributing to the Django Project.

- [django-core-mentorship mailing archive](#)
- [django-core-mentorship subscription email address](#)
- [django-core-mentorship posting email](#)

### 10.2.3 django-developers

The discussion about the development of Django itself takes place here.

---

**Note:** Please make use of *django-users mailing list* if you want to ask for tech support, doing so in this list is inappropriate.

---

- [django-developers mailing archive](#)
- [django-developers subscription email address](#)
- [django-developers posting email](#)

## 10.2.4 django-i18n

This is the place to discuss the internationalization and localization of Django's components.

- [django-i18n mailing archive](#)
- [django-i18n subscription email address](#)
- [django-i18n posting email](#)

## 10.2.5 django-announce

A (very) low-traffic list for announcing *upcoming security releases*, new releases of Django, and security advisories.

- [django-announce mailing archive](#)
- [django-announce subscription email address](#)
- [django-announce posting email](#)

## 10.2.6 django-updates

All the ticket updates are mailed automatically to this list, which is tracked by developers and interested community members.

- [django-updates mailing archive](#)
- [django-updates subscription email address](#)
- [django-updates posting email](#)

# 10.3 Organization of the Django Project

## 10.3.1 Principles

The Django Project is managed by a team of volunteers pursuing three goals:

- Driving the development of the Django Web Framework,
- Fostering the ecosystem of Django-related software,
- Leading the Django community in accordance with the values described in the [Django Code of Conduct](#).

The Django Project isn't a legal entity. The [Django Software Foundation](#), a non-profit organization, handles financial and legal matters related to the Django Project. Other than that, the Django Software Foundation lets the Django Project manage the development of the Django framework, its ecosystem and its community.

The Django core team makes the decisions, nominates its new members, and elects its technical board. While it holds decision power in theory, it aims at using it as rarely as possible in practice. Rough consensus should be the norm and formal voting an exception.

### 10.3.2 Core team

#### Role

The core team is the group of trusted volunteers who manage the Django Project. They assume many roles required to achieve the project's goals, especially those that require a high level of trust. They make the decisions that shape the future of the project.

Core team members are expected to act as role models for the community and custodians of the project, on behalf of the community and all those who rely on Django.

They will intervene, where necessary, in online discussions or at official Django events on the rare occasions that a situation arises that requires intervention.

They have authority over the Django Project infrastructure, including the Django Project website itself, the Django GitHub organization and repositories, the Trac bug tracker, the mailing lists, IRC channels, etc.

#### Prerogatives

Core team members may participate in formal votes, typically to nominate new team members and to elect the technical board.

Some contributions don't require commit access. Depending on the reasons why a contributor joins the team, they may or may not have commit permissions to the Django code repository.

However, should the need arise, any team member may ask for commit access by writing to the core team's mailing list. Access will be granted unless the person withdraws their request or the technical board vetoes the proposal.

Core team members who have commit access are referred to as "committers" or "core developers".

Other permissions, such as access to the servers, are granted to those who need them through the same process.

#### Membership

The core team finds its origins with the *four people* who created Django. It has grown to *a few dozen people* by co-opting volunteers who demonstrate:

- a good grasp of the philosophy of the Django Project
- a solid track record of being constructive and helpful
- significant contributions to the project's goals, in any form
- willingness to dedicate some time to improving Django

As the project matures, contributions go way beyond code. Here's an incomplete list of areas where contributions may be considered for joining the core team, in no particular order:

- Working on community management and outreach
- Providing support on the mailing-lists and on IRC

- Triaging tickets
- Writing patches (code, docs, or tests)
- Reviewing patches (code, docs, or tests)
- Participating in design decisions
- Providing expertise in a particular domain (security, i18n, etc.)
- Managing the continuous integration infrastructure
- Managing the servers (website, tracker, documentation, etc.)
- Maintaining related projects (djangoproject.com site, ex-contrib apps, etc.)
- Creating visual designs

Very few areas are reserved to core team members:

- Reviewing security reports
- Merging patches (code, docs, or tests)
- Packaging releases

Core team membership acknowledges sustained and valuable efforts that align well with the philosophy and the goals of the Django Project.

It is granted by a four fifths majority of votes cast in a core team vote and no veto by the technical board.

Core team members are always looking for promising contributors, teaching them how the project is managed, and submitting their names to the core team's vote when they're ready. If you would like to join the core team, you can contact a core team member privately or ask for guidance on the [Django Core Mentorship mailing-list](#).

There's no time limit on core team membership. However, in order to provide the general public with a reasonable idea of how many people maintain Django, core team members who have stopped contributing are encouraged to declare themselves as "past team members". Those who haven't made any non-trivial contribution in two years may be asked to move themselves to this category, and moved there if they don't respond. Past team members lose their privileges such as voting rights and commit access.

### 10.3.3 Technical board

#### Role

The technical board is a group of experienced and active committers who steer technical choices. Their main concern is to maintain the quality and stability of the Django Web Framework.

#### Prerogatives

The technical board holds two prerogatives:

- Making major technical decisions when no consensus is found otherwise. This happens on the [django-developers](#) mailing-list.
- Veto a grant of commit access or remove commit access. This happens on the `django-core` mailing-list.

In both cases, the technical board is a last resort. In these matters, it fulfills a similar function to the former Benevolent Dictators For Life.

When the board wants to exercise one of these prerogatives, it must hold a private, simple majority vote on the resolution. The quorum is the full committee — each member must cast a vote or abstain explicitly. Then the board

communicates the result, and if possible the reasons, on the appropriate mailing-list. There's no appeal for such decisions.

In addition, at its discretion, the technical board may act in an advisory capacity on non-technical decisions.

## Membership

The technical board is an elected group of five committers. They're expected to be experienced but there's no formal seniority requirement. Its current composition is published [here](#).

A new board is elected after each feature release of Django. The election process is managed by a returns officer nominated by the outgoing technical board. The election process works as follows:

1. Candidates advertise their application for the technical board to the team.  
They must be committers already. There's no term limit for technical board members.
2. Each team member can vote for zero to five people among the candidates. Candidates are ranked by the total number of votes they received.

In case of a tie, the person who joined the core team earlier wins.

Both the application and the voting period last between one and two weeks, at the outgoing board's discretion.

## 10.3.4 Changing the organization

Changes to this document require a four fifths majority of votes cast in a core team vote and no veto by the technical board.

# 10.4 Django team

## 10.4.1 The original team

Django originally started at World Online, the Web department of the [Lawrence Journal-World](#) of Lawrence, Kansas, USA.

**Adrian Holovaty** Adrian is a Web developer with a background in journalism. He's known in journalism circles as one of the pioneers of "journalism via computer programming", and in technical circles as "the guy who invented Django."

He was lead developer at World Online for 2.5 years, during which time Django was developed and implemented on World Online's sites. He was the leader and founder of [EveryBlock](#), a "news feed for your block." He now develops [Soundslice](#).

Adrian lives in Chicago, USA.

**Simon Willison** Simon is a well-respected Web developer from England. He had a one-year internship at World Online, during which time he and Adrian developed Django from scratch. The most enthusiastic Brit you'll ever meet, he's passionate about best practices in Web development and maintains a well-read [web-development blog](#).

Simon lives in Brighton, England.

**Jacob Kaplan-Moss** Jacob is Director of Platform Security at [Heroku](#). He worked at World Online for four years, where he helped open source Django and found the Django Software Foundation. Jacob lives on a hobby farm outside of Lawrence where he spends his weekends playing with dirt and power tools.

**Wilson Miner** Wilson’s design-fu is what makes Django look so nice. He created the design that was used for nearly the first ten years on the Django Project website, as well as the current design for Django’s acclaimed admin interface. Wilson was the designer for EveryBlock and [Rdio](#). He now designs for Facebook.

Wilson lives in San Francisco, USA.

## 10.4.2 The current team

These are the folks who have a long history of contributions, a solid track record of being helpful on the mailing lists, and a proven desire to dedicate serious time to Django. In return, they’ve been invited to join the *core team*.

**Luke Plant** At University Luke studied physics and Materials Science and also met [Michael Meeks](#) who introduced him to Linux and Open Source, re-igniting an interest in programming. Since then he has contributed to a number of Open Source projects and worked professionally as a developer.

Luke has contributed many excellent improvements to Django, including database-level improvements, the CSRF middleware and many unit tests.

Luke currently works for a church in Bradford, UK, and part-time as a freelance developer.

**Russell Keith-Magee** Russell studied physics as an undergraduate, and studied neural networks for his PhD. His first job was with a startup in the defense industry developing simulation frameworks. Over time, mostly through work with Django, he’s become more involved in Web development.

Russell has helped with several major aspects of Django, including a couple major internal refactorings, creation of the test system, and more.

Russell lives in the most isolated capital city in the world — Perth, Australia.

**James Bennett** James has been one of Django’s release managers, and also contributes to the documentation and provide the occasional bugfix.

James came to Web development from philosophy when he discovered that programmers get to argue just as much while collecting much better pay. He lives in San Mateo, California and previously worked at World Online and Mozilla; currently, he’s part of the Web engineering team at [Clover](#).

He [keeps a blog](#), and enjoys fine port and talking to his car.

**Justin Bronn** Justin Bronn is a computer scientist and attorney specializing in legal topics related to intellectual property and spatial law.

In 2007, Justin began developing `django.contrib.gis` in a branch, a.k.a. [GeoDjango](#), which was merged in time for Django 1.0. While implementing GeoDjango, Justin obtained a deep knowledge of Django’s internals including the ORM, the admin, and Oracle support.

Justin lives in Houston, TX.

**Karen Tracey** Karen has a background in distributed operating systems (graduate school), communications software (industry) and crossword puzzle construction (freelance). The last of these brought her to Django, in late 2006, when she set out to put a Web front-end on her crossword puzzle database. That done, she stuck around in the community answering questions, debugging problems, etc. – because coding puzzles are as much fun as word puzzles.

Karen lives in Apex, NC, USA.

**Jannis Leidel** Jannis graduated in media design from [Bauhaus-University Weimar](#), is the author of a number of pluggable Django apps and likes to contribute to Open Source projects like [virtualenv](#) and [pip](#).

He has worked on Django’s auth, admin and staticfiles apps as well as the form, core, internationalization and test systems. He currently works at [Mozilla](#).

Jannis lives in Berlin, Germany.

**Andrew Godwin** Andrew is a freelance Python developer and tinkerer, and has been developing against Django since 2007. He graduated from Oxford University with a degree in Computer Science, and has become most well known in the Django community for his work on South, the schema migrations library.

Andrew lives in San Francisco, CA, USA.

**Carl Meyer** Carl has been a Django user since 2007 (long enough to remember queryset-refactor, but not magic-removal), and builds web apps at [OddBird](#). He became a Django contributor by accident, because fixing bugs is more interesting than working around them.

Carl lives in Rapid City, SD, USA.

**Ramiro Morales** Ramiro has been reading Django source code and submitting patches since mid-2006 after researching for a Python Web tool with matching awesomeness and being pointed to it by an old ninja.

A software developer in the electronic transactions industry, he is a living proof of the fact that anyone with enough enthusiasm can contribute to Django, learning a lot and having fun in the process.

Ramiro lives in Córdoba, Argentina.

**Chris Beaven** Chris has been submitting patches and suggesting crazy ideas for Django since early 2006. An advocate for community involvement and a long-term triager, he is still often found answering questions in the [#django](#) IRC channel.

Chris lives in Napier, New Zealand (adding to the pool of Oceanic core developers). He works remotely as a developer for [Lincoln Loop](#).

**Honza Král** Honza first discovered Django in 2006 and started using it right away, first for school and personal projects and later in his full-time job. He contributed various patches and fixes mostly to the newforms library, newforms admin and, through participation in the Google Summer of Code project, assisted in creating the [model validation](#) functionality.

He is currently working for [Whiskey Media](#) in San Francisco developing awesome sites running on pure Django.

**Tim Graham** When exploring Web frameworks for an independent study project in the fall of 2008, Tim discovered Django and was lured to it by the documentation. He enjoys contributing to the docs because they're awesome.

Tim works as a software engineer and lives in Philadelphia, PA, USA.

**Paul McMillan** Paul found Django in 2008 while looking for a more structured approach to web programming. He stuck around after figuring out that the developers of Django had already invented many of the wheels he needed. His passion for breaking (and then fixing) things led to his current role working to maintain and improve the security of Django.

**Julien Phalip** Julien has a background in software engineering and human-computer interaction. As a Web developer, he enjoys tinkering with the backend as much as designing and coding user interfaces. Julien discovered Django in 2007 while doing his PhD in Computing Sciences. Since then he has contributed patches to various components of the framework, in particular the admin. Julien was a co-founder of the [Interaction Consortium](#). He now works at [Odopod](#), a digital agency based in San Francisco, CA, USA.

**Aymeric Augustin** Aymeric is an engineer with a background in mathematics and computer science. He chose Django because he believes that software should be simple, explicit and tested. His perfectionist tendencies quickly led him to triage tickets and contribute patches.

Aymeric has a pragmatic approach to software engineering, can't live without a continuous integration server, and likes proving that Django is a good choice for enterprise software.

**Claude Paroz** Claude is a former teacher who fell in love with free software at the beginning of the 21st century. He's now working as freelancer in Web development in his native Switzerland. He has found in Django a perfect match for his needs of a stable, clean, documented and well-maintained Web framework.

He's also helping the GNOME Translation Project as maintainer of the Django-based [110n.gnome.org](#).

**Anssi Kääriäinen** Anssi works as a developer at Finnish National Institute for Health and Welfare. He is also a computer science student at Aalto University. In his work he uses Django for developing internal business applications and sees Django as a great match for that use case.

Anssi is interested in developing the object relational mapper (ORM) and all related features. He's also a fan of benchmarking and he tries keep Django as fast as possible.

**Florian Apolloner** Florian is currently studying Physics at the [Graz University of Technology](#). Soon after he started using Django he joined the [Ubuntuusers webteam](#) to work on *Inyoka*, the software powering the whole Ubuntu-users site.

For the time being he lives in Graz, Austria (not Australia ;)).

**Jeremy Dunck** Jeremy was rescued from corporate IT drudgery by Free Software and, in part, Django. Many of Jeremy's interests center around access to information.

Jeremy was the lead developer of Pegasus News, one of the first uses of Django outside World Online, and has since joined Votizen, a startup intent on reducing the influence of money in politics.

He serves as DSF Secretary, organizes and helps organize sprints, cares about the health and equity of the Django community. He has gone an embarrassingly long time without a working blog.

Jeremy lives in Mountain View, CA, USA.

**Bryan Veloso** Bryan found Django 0.96 through a fellow designer who was evangelizing its use. It was his first foray outside of the land that was PHP-based templating. Although he has only ever used Django for personal projects, it is the very reason he considers himself a designer/developer hybrid and is working to further design within the Django community.

Bryan works as a designer at GitHub by day, and masquerades as a [vlogger](#) and [shoutcaster](#) in the after-hours. Bryan lives in Los Angeles, CA, USA.

**Simon Charette** Simon is a mathematics student who discovered Django while searching for a replacement framework to an in-house PHP entity. Since that faithful day Django has been a big part of his life. So far, he's been involved in some ORM and forms API fixes.

Apart from contributing to multiple open source projects he spends most of his spare-time playing [Ultimate Frisbee](#) and working part-time at this awesome place called [Reptiletech](#).

Simon lives in Montréal, Québec, Canada.

**Donald Stufft** Donald found Python and Django in 2007 while trying to find a language, and web framework that he really enjoyed using after many years of PHP. He fell in love with the beauty of Python and the way Django made tasks simple and easy. His contributions to Django focus primarily on ensuring that it is and remains a secure web framework.

Donald currently works at [Nebula Inc](#) as a Software Engineer for their security team and lives in the Greater Philadelphia Area.

**Marc Tamlyn** Marc started life on the web using Django 1.2 back in 2010, and has never looked back. He was involved with rewriting the class-based view documentation at DjangoCon EU 2012, and also helped to develop [CCBV](#), an additional class-based view reference tool.

Marc is currently a full-time parent, part-time developer, and lives in Oxford, UK.

**Shai Berger** Shai started working with Python back in 1998, and with Django just before 1.0. He is a Free Software enthusiast, but life happens, and he was driven by consulting gigs to contribute to the Oracle and SQL Server backends of South, and then the Oracle backend of Django itself. Finally, he joined core to help maintain the Oracle backend.

Shai works for [Platonix](#), a small consulting company he started with a few friends in 1996, and lives near Tel Aviv, Israel.

**Baptiste Mispelon** Baptiste discovered Django around the 1.2 version and promptly switched away from his home-grown PHP framework. He started getting more involved in the project after attending DjangoCon EU 2012, mostly by triaging tickets and submitting small patches.

Baptiste currently lives in Budapest, Hungary and works for [M2BPO](#), a small French company providing services to architects.

**Daniele Procida** Daniele unexpectedly became a Django developer on 29th April 2009. Since then he has relied daily on Django's documentation, which has been a constant companion to him. More recently he has been able to contribute back to the project by helping improve the documentation itself.

He is the author of [Arkestra](#) and [Don't be afraid to commit](#). He lives in Cardiff, Wales, and works for [Divio](#).

**Erik Romijn** Erik started using Django in the days of 1.2. His largest contribution to Django was `GenericIPAddressField`, and he has worked on all sorts of patches since. While developing with Django, he always keeps a little list of even the slightest Django frustrations, to tackle them at a later time and prevent other developers from having to deal with the same issues.

Erik is an independent app maker, mostly developing web and mobile apps, as [Solid Links](#). He also enjoys helping ordinary developers to build safer web apps, for which Django is already a great start, and developed [Erik's Pony Checkup](#) with that goal in mind. Erik lives in Amsterdam, The Netherlands.

**Loïc Bistuer** Loïc studied telecommunications engineering and works as an independent software developer and consultant.

He discovered Django in 2008 shortly before the 1.0 release and has been hooked ever since. He contributes mostly to Django's ORM and Form components. His main contributions include advanced query prefetching, streamlining QuerySet and Manager to improve query reusability, and a significant refactor of forms error handling.

Loïc is originally from the South of France and currently lives in Bangkok, Thailand.

**Michael Manfre** Michael started running Django on Windows against a Microsoft SQL Server (MSSQL) database in 2008. He quickly became the maintainer of the `django-mssql` database backend. Much of his involvement with Django relates to the ORM, the private 3rd party database API, and using Django on Windows.

Michael lives in Cary, NC, USA.

**Collin Anderson** Collin found Django in November 2006. He was in awe of the admin and ORM and was amazed that the documentation was teaching him best web practices like redirecting after a successful POST request. Why had he never learned this before? No one knows to this day.

He enjoys helping people on the [django-users](#) mailing list and making Django simple and easy for newcomers.

Collin lives in South Bend, IN, USA where he uses Django to [increase unity](#).

**Tom Christie** Tom has background in speech recognition, networking, and web development. He has a particular interest in Web API design and is the original author of [Django REST framework](#).

Tom lives in the seaside city of Brighton, UK.

**Curtis Maloney** Curtis is a self-taught programmer from Melbourne, Australia, who eschews specialization. Upon finding Django when it was first open sourced, he realized it was possible to enjoy web development.

He spends a lot of time helping people on the [#django](#) IRC channel, and has authored and released a number of smaller Django apps.

**Markus Holtermann** Markus is a senior backend developer at [LaterPay](#) in Munich. He studied Computer Science at the [Technical University of Berlin](#). He started working with Django in 2010 when he joined the [ubuntuusers.de](#) web team to work on [Inyoka](#). Markus made his first contribution to the Django project during DjangoCon Europe 2013 in Warsaw. He was the web team leader for the [EuroPython 2014 website](#) and started regular contributions to Django after that.

Markus lives in Berlin, Germany.

**Josh Smeaton** Josh was given the opportunity to work on a new Django app around version 1.1 after working with a homegrown PHP reporting framework. The simplicity of the ORM and the power of the Admin were extremely liberating.

Still being involved with custom reporting applications, he decided to try his hand at improving the ORM support for analytics. His contributions focus on giving more power to users of the ORM.

Josh lives in Melbourne, Australia where he heads up development for a SaaS telecommunications company.

**Preston Timmons** Preston is a software developer with a background in mathematics. He enjoys Django because it enables consistent, simple, and tested systems to be built that even new programmers can quickly dive into. Preston lives in Dallas, TX.

**Tomek Paczkowski** Tomek started using Django in 2007 as a tool for quickly dealing with university projects. Since then, he worked with various technologies like Ruby on Rails, JavaScript and Android but always returned to Python and Django.

Tomek loves the Django community. He organized multiple Django sprints, co-organized [DjangoCon Europe 2013](#) and has mentored at many [Django Girls](#) events.

Originally from Poland, Tomek currently lives in London, where he works at [Squirrel](#).

**Ola Sitarska** Ola started working with Django in 2009, when she discovered the power of the Django admin and quickly fell in love with the beauty of Python.

She co-organized [DjangoCon Europe 2013](#) in Warsaw and co-authored the [Django Girls Tutorial](#), the most beginner friendly Django tutorial out there. Together with Ola Sendekca, she started [Django Girls](#), a community and series of Django workshops for women who've never programmed before.

In 2015, she became a Django Software Foundation board member. Ola was also a part of the team responsible for shipping the [djangoproject.com](#) redesign.

Originally from Poland, Ola currently lives in London, where she works with friends at [Potato](#).

**Ola Sendekca** Ola started her adventure with Django when writing a university project in 2009. After that she attended her first DjangoCon Europe which defined her future life as a Django professional.

Since then she has been an active community member. Ola co-organized a number of Django sprints and conferences including: [DjangoCon Europe 2013](#), [Django Under the Hood 2015](#) and [DjangoCon Europe 2016](#). Together with Ola Sitarska she founded [Django Girls](#), co-authored the [Django Girls Tutorial](#) and is a member of the Django Girls Foundation. She is also an author of the [Coding is for Girls](#) YouTube series teaching programming and Django to beginners.

Originally from Poland, Ola currently lives in London, where she works for [Potato](#).

### 10.4.3 Past team members

**Georg “Hugo” Bauer** Georg created Django’s internationalization system, managed 118n contributions and made a ton of excellent tweaks, feature additions and bug fixes.

**Robert Wittams** Robert was responsible for the *first* refactoring of Django’s admin application to allow for easier reuse and has made a ton of excellent tweaks, feature additions and bug fixes.

**Alex Gaynor** Alex was involved in many parts of Django, he contributed to the ORM, forms, admin, amongst others; he is most known for his work on multiple-database support in Django.

Alex lives in Washington, DC, USA.

**Simon Meers** Simon discovered Django 0.96 during his Computer Science PhD research and has been developing with it full-time ever since. His core code contributions are mostly in Django’s admin application.

Simon works as a freelance developer based in Wollongong, Australia.

**Gabriel Hurley** Gabriel has been working with Django since 2008, shortly after the 1.0 release. Convinced by his business partner that Python and Django were the right direction for the company, he couldn't have been more happy with the decision. His contributions range across many areas in Django, but years of copy-editing and an eye for detail lead him to be particularly at home while working on Django's documentation.

Gabriel works as a developer in the SF Bay Area, CA, USA.

**Malcolm Tredinnick** Malcolm originally wanted to be a mathematician and somehow ended up a software developer. He contributed to many Open Source projects, served on the board of the GNOME foundation, and was a great chess player.

Malcolm was deeply involved in many part of Django - most notably, the ORM, but many other internals bear his fingerprints. Django's support for unicode and autoescaping in templates can both be almost entirely attributed to Malcolm.

He was an International Man of Mystery and lived in Sydney, Australia.

*Malcolm passed away on March 17, 2013.*

**Preston Holmes** Preston is a recovering neuroscientist who originally discovered Django as part of a sweeping move to Python from a grab bag of half a dozen languages. He was drawn to Django's balance of practical batteries included philosophy, care and thought in code design, and strong open source community. Currently working in the rent-your-infra space (aka Cloud), he is always looking for opportunities to volunteer for community oriented education projects, such as for kids and scientists (e.g. Software Carpentry).

Preston lives with his family and animal menagerie in Santa Barbara, CA, USA.

**Idan Gazit** As a self-professed design geek, Idan was initially attracted to Django sometime between magic-removal and queryset-refactor. Formally trained as a software engineer, Idan straddles the worlds of design and code, jack of two trades and master of none. He is passionate about usability and finding novel ways to extract meaning from data, and is a longtime [photographer](#).

Idan is currently hacking on all things data and visualization at [Heroku](#).

**Matt Boersma** Matt helped with Django's Oracle support.

**Ian Kelly** Ian also helped with Oracle support.

**Joseph Kocherhans** Joseph was the director of lead development at EveryBlock and previously developed at the Lawrence Journal-World. He often disappears for several days into the woods, attempts to teach himself computational linguistics, and annoys his neighbors with his [Charango](#) playing.

Joseph's first contribution to Django was a series of improvements to the authorization system leading up to support for pluggable authorization. Since then, he's worked on the new forms system, its use in the admin, and many other smaller improvements.

Joseph lives in Chicago, USA.

**Gary Wilson** Gary starting contributing patches to Django in 2006 while developing Web applications for [The University of Texas](#) (UT). Since, he has made contributions to the email and forms systems, as well as many other improvements and code cleanups throughout the code base.

Gary lives in Austin, Texas, USA.

**Brian Rosner** Brian enjoys learning more about programming languages and system architectures and contributing to open source projects.

He helped immensely in getting Django's "newforms-admin" branch finished in time for Django 1.0.

Brian lives in Denver, Colorado, USA.

**James Tauber** James is the lead developer of [Pinax](#) and the CEO and founder of [Eldarion](#). He has been doing open source software since 1993, Python since 1998 and Django since 2006. He serves on the board of the Python Software Foundation and is currently on a leave of absence from a PhD in linguistics.

James currently lives in Boston, MA, USA but originally hails from Perth, Western Australia where he attended the same high school as Russell Keith-Magee.

## 10.5 Roles

### 10.5.1 Technical board

The technical board for the 1.10 release cycle is:

- James Bennett
- Andrew Godwin
- Russell Keith-Magee
- Carl Meyer
- Marc Tamlyn

### 10.5.2 Committers

Most *core team* members have commit access. They're called "committers" or "core developers".

Being part of the core team is a pre-requisite for having commit access.

### 10.5.3 Security team

The security team is responsible for *Django's security policies*. It handles private reports of security issues.

The current security team members are:

- Florian Apolloner
- James Bennett
- Tim Graham
- Adrian Holovaty
- Markus Holtermann
- Paul McMillan
- Carl Meyer

### 10.5.4 Releasers

Releasers take care of *building Django releases*.

The current releasers are:

- James Bennett
- Jacob Kaplan-Moss

- Tim Graham

### 10.5.5 Ops team

The ops team maintains Django's infrastructure like the Django Project server, Trac instance, and continuous integration infrastructure.

- Florian Apolloner
- Aymeric Augustin
- Tim Graham
- Markus Holtermann
- Jannis Leidel

## 10.6 Django's security policies

Django's development team is strongly committed to responsible reporting and disclosure of security-related issues. As such, we've adopted and follow a set of policies which conform to that ideal and are geared toward allowing us to deliver timely security updates to the official distribution of Django, as well as to third-party distributions.

### 10.6.1 Reporting security issues

**Short version: please report security issues by emailing [security@djangoproject.com](mailto:security@djangoproject.com).**

Most normal bugs in Django are reported to [our public Trac instance](#), but due to the sensitive nature of security issues, we ask that they **not** be publicly reported in this fashion.

Instead, if you believe you've found something in Django which has security implications, please send a description of the issue via email to [security@djangoproject.com](mailto:security@djangoproject.com). Mail sent to that address reaches a *subset of the core team*, who can forward security issues into the private team's mailing list for broader discussion if needed.

Once you've submitted an issue via email, you should receive an acknowledgment from a member of the security team within 48 hours, and depending on the action to be taken, you may receive further followup emails.

---

#### Sending encrypted reports

If you want to send an encrypted email (*optional*), the public key ID for [security@djangoproject.com](mailto:security@djangoproject.com) is `0xfcb84b8d1d17f80b`, and this public key is available from most commonly-used key servers.

---

### 10.6.2 Supported versions

At any given time, the Django team provides official security support for several versions of Django:

- The [master development branch](#), hosted on GitHub, which will become the next major release of Django, receives security support. Security issues that only affect the master development branch and not any stable released versions are fixed in public without going through the *disclosure process*.
- The two most recent Django release series receive security support. For example, during the development cycle leading to the release of Django 1.5, support will be provided for Django 1.4 and Django 1.3. Upon the release of Django 1.5, Django 1.3's security support will end.

- *Long-term support releases* will receive security updates for a specified period.

When new releases are issued for security reasons, the accompanying notice will include a list of affected versions. This list is comprised solely of *supported* versions of Django: older versions may also be affected, but we do not investigate to determine that, and will not issue patches or new releases for those versions.

### 10.6.3 How Django discloses security issues

Our process for taking a security issue from private discussion to public disclosure involves multiple steps.

Approximately one week before public disclosure, we send two notifications:

First, we notify *django-announce* of the date and approximate time of the upcoming security release, as well as the severity of the issues. This is to aid organizations that need to ensure they have staff available to handle triaging our announcement and upgrade Django as needed. Severity levels are:

**High:**

- Remote code execution
- SQL injection

**Moderate:**

- Cross site scripting (XSS)
- Cross site request forgery (CSRF)
- Broken authentication

**Low:**

- Sensitive data exposure
- Broken session management
- Unvalidated redirects/forwards
- Issues requiring an uncommon configuration option

Second, we notify a list of *people and organizations*, primarily composed of operating-system vendors and other distributors of Django. This email is signed with the PGP key of someone from *Django's release team* and consists of:

- A full description of the issue and the affected versions of Django.
- The steps we will be taking to remedy the issue.
- The patch(es), if any, that will be applied to Django.
- The date on which the Django team will apply these patches, issue new releases and publicly disclose the issue.

On the day of disclosure, we will take the following steps:

1. Apply the relevant patch(es) to Django's codebase.
2. Issue the relevant release(s), by placing new packages on [the Python Package Index](#) and on the Django website, and tagging the new release(s) in Django's git repository.
3. Post a public entry on [the official Django development blog](#), describing the issue and its resolution in detail, pointing to the relevant patches and new releases, and crediting the reporter of the issue (if the reporter wishes to be publicly identified).
4. Post a notice to the *django-announce* and [oss-security@lists.openwall.com](mailto:oss-security@lists.openwall.com) mailing lists that links to the blog post.

If a reported issue is believed to be particularly time-sensitive – due to a known exploit in the wild, for example – the time between advance notification and public disclosure may be shortened considerably.

Additionally, if we have reason to believe that an issue reported to us affects other frameworks or tools in the Python/web ecosystem, we may privately contact and discuss those issues with the appropriate maintainers, and coordinate our own disclosure and resolution with theirs.

The Django team also maintains an *archive of security issues disclosed in Django*.

## 10.6.4 Who receives advance notification

The full list of people and organizations who receive advance notification of security issues is not and will not be made public.

We also aim to keep this list as small as effectively possible, in order to better manage the flow of confidential information prior to disclosure. As such, our notification list is *not* simply a list of users of Django, and merely being a user of Django is not sufficient reason to be placed on the notification list.

In broad terms, recipients of security notifications fall into three groups:

1. Operating-system vendors and other distributors of Django who provide a suitably-generic (i.e., *not* an individual’s personal email address) contact address for reporting issues with their Django package, or for general security reporting. In either case, such addresses **must not** forward to public mailing lists or bug trackers. Addresses which forward to the private email of an individual maintainer or security-response contact are acceptable, although private security trackers or security-response groups are strongly preferred.
2. On a case-by-case basis, individual package maintainers who have demonstrated a commitment to responding to and responsibly acting on these notifications.
3. On a case-by-case basis, other entities who, in the judgment of the Django development team, need to be made aware of a pending security issue. Typically, membership in this group will consist of some of the largest and/or most likely to be severely impacted known users or distributors of Django, and will require a demonstrated ability to responsibly receive, keep confidential and act on these notifications.

## 10.6.5 Requesting notifications

If you believe that you, or an organization you are authorized to represent, fall into one of the groups listed above, you can ask to be added to Django’s notification list by emailing `security@django-project.com`. Please use the subject line “Security notification request”.

Your request **must** include the following information:

- Your full, real name and the name of the organization you represent, if applicable, as well as your role within that organization.
- A detailed explanation of how you or your organization fit at least one set of criteria listed above.
- A detailed explanation of why you are requesting security notifications. Again, please keep in mind that this is *not* simply a list for users of Django, and the overwhelming majority of users should subscribe to *django-announce* to receive advanced notice of when a security release will happen, without the details of the issues, rather than request detailed notifications.
- The email address you would like to have added to our notification list.
- An explanation of who will be receiving/reviewing mail sent to that address, as well as information regarding any automated actions that will be taken (i.e., filing of a confidential issue in a bug tracker).
- For individuals, the ID of a public key associated with your address which can be used to verify email received from you and encrypt email sent to you, as needed.

Once submitted, your request will be considered by the Django development team; you will receive a reply notifying you of the result of your request within 30 days.

Please also bear in mind that for any individual or organization, receiving security notifications is a privilege granted at the sole discretion of the Django development team, and that this privilege can be revoked at any time, with or without explanation.

## 10.7 Django’s release process

### 10.7.1 Official releases

Since version 1.0, Django’s release numbering works as follows:

- Versions are numbered in the form `A.B` or `A.B.C`.
- `A.B` is the *feature release* version number. Each version will be mostly backwards compatible with the previous release. Exceptions to this rule will be listed in the release notes.
- `C` is the *patch release* version number, which is incremented for bugfix and security releases. These releases will be 100% backwards-compatible with the previous patch release. The only exception is when a security or data loss issue can’t be fixed without breaking backwards-compatibility. If this happens, the release notes will provide detailed upgrade instructions.
- Before a new feature release, we’ll make alpha, beta, and release candidate releases. These are of the form `A.B.alpha/beta/rc N`, which means the `N`th alpha/beta/release candidate of version `A.B`.

In git, each Django release will have a tag indicating its version number, signed with the Django release key. Additionally, each release series has its own branch, called `stable/A.B.x`, and bugfix/security releases will be issued from those branches.

For more information about how the Django project issues new releases for security purposes, please see [our security policies](#).

**Feature release** Feature releases (`A.B`, `A.B+1`, etc.) will happen roughly every eight months – see [release process](#) for details. These releases will contain new features, improvements to existing features, and such.

**Patch release** Patch releases (`A.B.C`, `A.B.C+1`, etc.) will be issued as needed, to fix bugs and/or security issues.

These releases will be 100% compatible with the associated feature release, unless this is impossible for security reasons or to prevent data loss. So the answer to “should I upgrade to the latest patch release?” will always be “yes.”

**Long-term support release** Certain feature releases will be designated as long-term support (LTS) releases. These releases will get security and data loss fixes applied for a guaranteed period of time, typically three years.

See the [download page](#) for the releases that have been designated for long-term support.

### 10.7.2 Release cadence

Starting with Django 2.0, version numbers will use a loose form of [semantic versioning](#) such that each version following an LTS will bump to the next “dot zero” version. For example: 2.0, 2.1, 2.2 (LTS), 3.0, 3.1, 3.2 (LTS), etc.

SemVer makes it easier to see at a glance how compatible releases are with each other. It also helps to anticipate when compatibility shims will be removed. It’s not a pure form of SemVer as each feature release will continue to have a few documented backwards incompatibilities where a deprecation path isn’t possible or not worth the cost. Also, deprecations started in an LTS release (`X.2`) will be dropped in a non-dot-zero release (`Y.1`) to accommodate our policy of keeping deprecation shims for at least two feature releases. Read on to the next section for an example.

### 10.7.3 Deprecation policy

A feature release may deprecate certain features from previous releases. If a feature is deprecated in feature release A.x, it will continue to work in all A.x versions (for all versions of x) but raise warnings. Deprecated features will be removed in the B.0 release, or B.1 for features deprecated in the last A.x feature release to ensure deprecations are done over at least 2 feature releases.

So, for example, if we decided to start the deprecation of a function in Django 4.2:

- Django 4.2 will contain a backwards-compatible replica of the function which will raise a `RemovedInDjango51Warning`.
- Django 5.0 (the version that follows 4.2) will still contain the backwards-compatible replica.
- Django 5.1 will remove the feature outright.

The warnings are silent by default. You can turn on display of these warnings with the `python -Wd` option.

A more generic example:

- X.0
- X.1
- X.2 LTS
- Y.0: Drop deprecation shims added in X.0 and X.1.
- Y.1: Drop deprecation shims added in X.2.
- Y.2 LTS: No deprecation shims dropped (while Y.0 is no longer supported, third-party apps need to maintain compatibility back to X.2 LTS to ease LTS to LTS upgrades).
- Z.0: Drop deprecation shims added in Y.0 and Y.1.

### 10.7.4 Supported versions

At any moment in time, Django's developer team will support a set of releases to varying levels. See the [supported versions section](#) of the download page for the current state of support for each version.

- The current development master will get new features and bug fixes requiring non-trivial refactoring.
- Patches applied to the master branch must also be applied to the last feature release branch, to be released in the next patch release of that feature series, when they fix critical problems:
  - Security issues.
  - Data loss bugs.
  - Crashing bugs.
  - Major functionality bugs in newly-introduced features.
  - Regressions from older versions of Django.

The rule of thumb is that fixes will be backported to the last feature release for bugs that would have prevented a release in the first place (release blockers).

- Security fixes and data loss bugs will be applied to the current master, the last two feature release branches, and any other supported long-term support release branches.
- Documentation fixes generally will be more freely backported to the last release branch. That's because it's highly advantageous to have the docs for the last release be up-to-date and correct, and the risk of introducing regressions is much less of a concern.

As a concrete example, consider a moment in time halfway between the release of Django 5.1 and 5.2. At this point in time:

- Features will be added to development master, to be released as Django 5.2.
- Critical bug fixes will be applied to the `stable/5.1.x` branch, and released as 5.1.1, 5.1.2, etc.
- Security fixes and bug fixes for data loss issues will be applied to `master` and to the `stable/5.1.x`, `stable/5.0.x`, and `stable/4.2.x` (LTS) branches. They will trigger the release of 5.1.1, 5.0.5, 4.2.8, etc.
- Documentation fixes will be applied to `master`, and, if easily backported, to the latest stable branch, 5.1.x.

### 10.7.5 Release process

Django uses a time-based release schedule, with feature releases every eight months or so.

After each feature release, the release manager will announce a timeline for the next feature release.

#### Release cycle

Each release cycle consists of three parts:

##### Phase one: feature proposal

The first phase of the release process will include figuring out what major features to include in the next version. This should include a good deal of preliminary work on those features – working code trumps grand design.

Major features for an upcoming release will be added to the wiki roadmap page, e.g. <https://code.djangoproject.com/wiki/Version1.9Roadmap>.

##### Phase two: development

The second part of the release schedule is the “heads-down” working period. Using the roadmap produced at the end of phase one, we’ll all work very hard to get everything on it done.

At the end of phase two, any unfinished features will be postponed until the next release.

Phase two will culminate with an alpha release. At this point, the `stable/A.B.x` branch will be forked from `master`.

##### Phase three: bugfixes

The last part of a release cycle is spent fixing bugs – no new features will be accepted during this time. We’ll try to release a beta release one month after the alpha and a release candidate one month after the beta.

The release candidate marks the string freeze, and it happens at least two weeks before the final release. After this point, new translatable strings must not be added.

During this phase, committers will be more and more conservative with backports, to avoid introducing regressions. After the release candidate, only release blockers and documentation fixes should be backported.

In parallel to this phase, `master` can receive new features, to be released in the `A.B+1` cycle.

## Bug-fix releases

After a feature release (e.g. A.B), the previous release will go into bugfix mode.

The branch for the previous feature release (e.g. `stable/A.B-1.x`) will include bugfixes. Critical bugs fixed on master must *also* be fixed on the bugfix branch; this means that commits need to cleanly separate bug fixes from feature additions. The developer who commits a fix to master will be responsible for also applying the fix to the current bugfix branch.

## 10.8 Django Deprecation Timeline

This document outlines when various pieces of Django will be removed or altered in a backward incompatible way, following their deprecation, as per the [deprecation policy](#). More details about each item can often be found in the release notes of two versions prior.

### 10.8.1 2.0

See the [Django 1.9 release notes](#) for more details on these changes.

- The weak argument to `django.dispatch.signals.Signal.disconnect()` will be removed.
- `django.db.backends.base.BaseDatabaseOperations.check_aggregate_support()` will be removed.
- The `django.forms.extras` package will be removed.
- The `assignment_tag` helper will be removed.
- The `host` argument to `assertsRedirects` will be removed. The compatibility layer which allows absolute URLs to be considered equal to relative ones when the path is identical will also be removed.
- `Field.rel` will be removed.
- `Field.remote_field.to_attribute` will be removed.
- The `on_delete` argument for `ForeignKey` and `OneToOneField` will be required.
- `django.db.models.fields.add_lazy_relation()` will be removed.
- When time zone support is enabled, database backends that don't support time zones won't convert aware datetimes to naive values in UTC anymore when such values are passed as parameters to SQL queries executed outside of the ORM, e.g. with `cursor.execute()`.
- The `django.contrib.auth.tests.utils.skipIfCustomUser()` decorator will be removed.
- The `GeoManager` and `GeoQuerySet` classes will be removed.
- The `django.contrib.gis.geopip` module will be removed.
- The `supports_recursion` check for template loaders will be removed from:
  - `django.template.engine.Engine.find_template()`
  - `django.template.loader_tags.ExtendsNode.find_template()`
  - `django.template.loaders.base.Loader.supports_recursion()`
  - `django.template.loaders.cached.Loader.supports_recursion()`
- The `load_template()` and `load_template_sources()` template loader methods will be removed.
- The `template_dirs` argument for template loaders will be removed:

- `django.template.loaders.base.Loader.get_template()`
- `django.template.loaders.cached.Loader.cache_key()`
- `django.template.loaders.cached.Loader.get_template()`
- `django.template.loaders.cached.Loader.get_template_sources()`
- `django.template.loaders.filesystem.Loader.get_template_sources()`
- The `django.template.loaders.base.Loader.__call__()` method will be removed.
- Support for custom error views with a single positional parameter will be dropped.
- The `mime_type` attribute of `django.utils.feedgenerator.Atom1Feed` and `django.utils.feedgenerator.RssFeed` will be removed in favor of `content_type`.
- The `app_name` argument to `include()` will be removed.
- Support for passing a 3-tuple as the first argument to `include()` will be removed.
- Support for setting a URL instance namespace without an application namespace will be removed.
- `Field._get_val_from_obj()` will be removed in favor of `Field.value_from_object()`.
- `django.template.loaders.eggs.Loader` will be removed.
- The `current_app` parameter to the `contrib.auth` views will be removed.
- The `callable_obj` keyword argument to `SimpleTestCase.assertRaisesMessage()` will be removed.
- Support for the `allow_tags` attribute on `ModelAdmin` methods will be removed.
- The `enclosure` keyword argument to `SyndicationFeed.add_item()` will be removed.
- The `django.template.loader.LoaderOrigin` and `django.template.base.StringOrigin` aliases for `django.template.base.Origin` will be removed.

See the [Django 1.10 release notes](#) for more details on these changes.

- The `makemigrations --exit` option will be removed.
- Support for direct assignment to a reverse foreign key or many-to-many relation will be removed.
- The `get_srid()` and `set_srid()` methods of `django.contrib.gis.geos.GEOSGeometry` will be removed.
- The `get_x()`, `set_x()`, `get_y()`, `set_y()`, `get_z()`, and `set_z()` methods of `django.contrib.gis.geos.Point` will be removed.
- The `get_coords()` and `set_coords()` methods of `django.contrib.gis.geos.Point` will be removed.
- The `cascaded_union` property of `django.contrib.gis.geos.MultiPolygon` will be removed.
- `django.utils.functional.allow_lazy()` will be removed.
- The `shell --plain` option will be removed.
- The `django.core.urlresolvers` module will be removed.
- The `model` `CommaSeparatedIntegerField` will be removed. A stub field will remain for compatibility with historical migrations.
- Support for the `template` `Context.has_key()` method will be removed.
- Support for the `django.core.files.storage.Storage.accessed_time()`, `created_time()`, and `modified_time()` methods will be removed.

- Support for query lookups using the model name when `Meta.default_related_name` is set will be removed.
- The `__search` query lookup and the `DatabaseOperations.fulltext_search_sql()` method will be removed.
- The shim for supporting custom related manager classes without a `_apply_rel_filters()` method will be removed.
- Using `User.is_authenticated()` and `User.is_anonymous()` as methods will no longer be supported.
- The private attribute `virtual_fields` of `Model._meta` will be removed.
- The private keyword arguments `virtual_only` in `Field.contribute_to_class()` and `virtual` in `Model._meta.add_field()` will be removed.
- The `javascript_catalog()` and `json_catalog()` views will be removed.
- The `django.contrib.gis.utils.precision_wkt()` function will be removed.
- In multi-table inheritance, implicit promotion of a `OneToOneField` to a `parent_link` will be removed.
- Support for `Widget._format_value()` will be removed.
- `FileField` methods `get_directory_name()` and `get_filename()` will be removed.
- The `mark_for_escaping()` function and the classes it uses: `EscapeData`, `EscapeBytes`, `EscapeText`, `EscapeString`, and `EscapeUnicode` will be removed.
- The escape filter will change to use `django.utils.html.conditional_escape()`.
- `Manager.use_for_related_fields` will be removed.
- `Model Manager` inheritance will follow `MRO` inheritance rules and the `Meta.manager_inheritance_from_future` to opt-in to this behavior will be removed.
- Support for old-style middleware using `settings.MIDDLEWARE_CLASSES` will be removed.

## 10.8.2 1.10

See the *Django 1.8 release notes* for more details on these changes.

- Support for calling a `SQLCompiler` directly as an alias for calling its `quote_name_unless_alias` method will be removed.
- `cycle` and `firstof` template tags will be removed from the future template tag library (used during the 1.6/1.7 deprecation period).
- `django.conf.urls.patterns()` will be removed.
- Support for the `prefix` argument to `django.conf.urls.i18n.i18n_patterns()` will be removed.
- `SimpleTestCase.urls` will be removed.
- Using an incorrect count of unpacked values in the `for` template tag will raise an exception rather than fail silently.
- The ability to reverse URLs using a dotted Python path will be removed.
- The ability to use a dotted Python path for the `LOGIN_URL` and `LOGIN_REDIRECT_URL` settings will be removed.
- Support for `optparse` will be dropped for custom management commands (replaced by `argparse`).

- The class `django.core.management.NoArgsCommand` will be removed. Use `BaseCommand` instead, which takes no arguments by default.
- `django.core.context_processors` module will be removed.
- `django.db.models.sql.aggregates` module will be removed.
- `django.contrib.gis.db.models.sql.aggregates` module will be removed.
- The following methods and properties of `django.db.sql.query.Query` will be removed:
  - Properties: `aggregates` and `aggregate_select`
  - Methods: `add_aggregate`, `set_aggregate_mask`, and `append_aggregate_mask`.
- `django.template.resolve_variable` will be removed.
- The following private APIs will be removed from `django.db.models.options.Options` (`Model._meta`):
  - `get_field_by_name()`
  - `get_all_field_names()`
  - `get_fields_with_model()`
  - `get_concrete_fields_with_model()`
  - `get_m2m_with_model()`
  - `get_all_related_objects()`
  - `get_all_related_objects_with_model()`
  - `get_all_related_many_to_many_objects()`
  - `get_all_related_m2m_objects_with_model()`
- The `error_message` argument of `django.forms.RegexField` will be removed.
- The `unordered_list` filter will no longer support old style lists.
- Support for string view arguments to `url()` will be removed.
- The backward compatible shim to rename `django.forms.Form._has_changed()` to `has_changed()` will be removed.
- The `removetags` template filter will be removed.
- The `remove_tags()` and `strip_entities()` functions in `django.utils.html` will be removed.
- The `is_admin_site` argument to `django.contrib.auth.views.password_reset()` will be removed.
- `django.db.models.field.subclassing.SubfieldBase` will be removed.
- `django.utils.checksums` will be removed; its functionality is included in `django-localflavor` 1.1+.
- The `original_content_type_id` attribute on `django.contrib.admin.helpers.InlineAdminForm` will be removed.
- The backwards compatibility shim to allow `FormMixin.get_form()` to be defined with no default value for its `form_class` argument will be removed.
- The following settings will be removed:
  - `ALLOWED_INCLUDE_ROOTS`

- `TEMPLATE_CONTEXT_PROCESSORS`
- `TEMPLATE_DEBUG`
- `TEMPLATE_DIRS`
- `TEMPLATE_LOADERS`
- `TEMPLATE_STRING_IF_INVALID`
- The backwards compatibility alias `django.template.loader.BaseLoader` will be removed.
- Django template objects returned by `get_template()` and `select_template()` won't accept a `Context` in their `render()` method anymore.
- *Template response APIs* will enforce the use of `dict` and backend-dependent template objects instead of `Context` and `Template` respectively.
- The `current_app` parameter for the following function and classes will be removed:
  - `django.shortcuts.render()`
  - `django.template.Context()`
  - `django.template.RequestContext()`
  - `django.template.response.TemplateResponse()`
- The `dictionary` and `context_instance` parameters for the following functions will be removed:
  - `django.shortcuts.render()`
  - `django.shortcuts.render_to_response()`
  - `django.template.loader.render_to_string()`
- The `dirs` parameter for the following functions will be removed:
  - `django.template.loader.get_template()`
  - `django.template.loader.select_template()`
  - `django.shortcuts.render()`
  - `django.shortcuts.render_to_response()`
- Session verification will be enabled regardless of whether or not `'django.contrib.auth.middleware.SessionAuthenticationMiddleware'` is in `MIDDLEWARE_CLASSES`.
- Private attribute `django.db.models.Field.related` will be removed.
- The `--list` option of the `migrate` management command will be removed.
- The `ssi` template tag will be removed.
- Support for the `=` comparison operator in the `if` template tag will be removed.
- The backwards compatibility shims to allow `Storage.get_available_name()` and `Storage.save()` to be defined without a `max_length` argument will be removed.
- Support for the legacy `%(<foo>)s` syntax in `ModelFormMixin.success_url` will be removed.
- `GeoQuerySet` aggregate methods `collect()`, `extent()`, `extent3d()`, `make_line()`, and `unionagg()` will be removed.
- Ability to specify `ContentType.name` when creating a content type instance will be removed.

- Support for the old signature of `allow_migrate` will be removed. It changed from `allow_migrate(self, db, model)` to `allow_migrate(self, db, app_label, model_name=None, **hints)`.
- Support for the syntax of `{% cycle %}` that uses comma-separated arguments will be removed.
- The warning that *Signer* issues when given an invalid separator will become an exception.

### 10.8.3 1.9

See the *Django 1.7 release notes* for more details on these changes.

- `django.utils.dictconfig` will be removed.
- `django.utils.importlib` will be removed.
- `django.utils.tzinfo` will be removed.
- `django.utils.unittest` will be removed.
- The `syncdb` command will be removed.
- `django.db.models.signals.pre_syncdb` and `django.db.models.signals.post_syncdb` will be removed.
- `allow_syncdb` on database routers will no longer automatically become `allow_migrate`.
- Automatic syncing of apps without migrations will be removed. Migrations will become compulsory for all apps unless you pass the `--run-syncdb` option to `migrate`.
- The SQL management commands for apps without migrations, `sql`, `sqlall`, `sqlclear`, `sqldropindexes`, and `sqlindexes`, will be removed.
- Support for automatic loading of `initial_data` fixtures and initial SQL data will be removed.
- All models will need to be defined inside an installed application or declare an explicit `app_label`. Furthermore, it won't be possible to import them before their application is loaded. In particular, it won't be possible to import models inside the root package of their application.
- The model and form `IPAddressField` will be removed. A stub field will remain for compatibility with historical migrations.
- `AppCommand.handle_app()` will no longer be supported.
- `RequestSite` and `get_current_site()` will no longer be importable from `django.contrib.sites.models`.
- FastCGI support via the `runfcgi` management command will be removed. Please deploy your project using WSGI.
- `django.utils.datastructures.SortedDict` will be removed. Use `collections.OrderedDict` from the Python standard library instead.
- `ModelAdmin.declared_fieldsets` will be removed.
- Instances of `util.py` in the Django codebase have been renamed to `utils.py` in an effort to unify all util and utils references. The modules that provided backwards compatibility will be removed:
  - `django.contrib.admin.util`
  - `django.contrib.gis.db.backends.util`
  - `django.db.backends.util`
  - `django.forms.util`

- `ModelAdmin.get_formsets` will be removed.
- The backward compatibility shim introduced to rename the `BaseMemcachedCache.get_memcache_timeout()` method to `get_backend_timeout()` will be removed.
- The `--natural` and `-n` options for `dumpdata` will be removed.
- The `use_natural_keys` argument for `serializers.serialize()` will be removed.
- Private API `django.forms.forms.get_declared_fields()` will be removed.
- The ability to use a `SplitDateTimeWidget` with `DateTimeField` will be removed.
- The `WSGIRequest.REQUEST` property will be removed.
- The class `django.utils.datastructures.MergeDict` will be removed.
- The `zh-cn` and `zh-tw` language codes will be removed and have been replaced by the `zh-hans` and `zh-hant` language code respectively.
- The internal `django.utils.functional.memoize` will be removed.
- `django.core.cache.get_cache` will be removed. Add suitable entries to `CACHES` and use `django.core.cache.caches` instead.
- `django.db.models.loading` will be removed.
- Passing callable arguments to queriesets will no longer be possible.
- `BaseCommand.requires_model_validation` will be removed in favor of `requires_system_checks`. Admin validators will be replaced by admin checks.
- The `ModelAdmin.validator_class` and `default_validator_class` attributes will be removed.
- `ModelAdmin.validate()` will be removed.
- `django.db.backends.DatabaseValidation.validate_field` will be removed in favor of the `check_field` method.
- The `validate` management command will be removed.
- `django.utils.module_loading.import_by_path` will be removed in favor of `django.utils.module_loading.import_string`.
- `ssi` and `url` template tags will be removed from the future template tag library (used during the 1.3/1.4 deprecation period).
- `django.utils.text.javascript_quote` will be removed.
- Database test settings as independent entries in the database settings, prefixed by `TEST_`, will no longer be supported.
- The `cache_choices` option to `ModelChoiceField` and `ModelMultipleChoiceField` will be removed.
- The default value of the `RedirectView.permanent` attribute will change from `True` to `False`.
- `django.contrib.sitemaps.FlatPageSitemap` will be removed in favor of `django.contrib.flatpages.sitemaps.FlatPageSitemap`.
- Private API `django.test.utils.TestTemplateLoader` will be removed.
- The `django.contrib.contenttypes.generic` module will be removed.
- Private APIs `django.db.models.sql.where.WhereNode.make_atom()` and `django.db.models.sql.where.Constraint` will be removed.

## 10.8.4 1.8

See the *Django 1.6 release notes* for more details on these changes.

- `django.contrib.comments` will be removed.
- The following transaction management APIs will be removed:
  - `TransactionMiddleware`,
  - the decorators and context managers `autocommit`, `commit_on_success`, and `commit_manually`, defined in `django.db.transaction`,
  - the functions `commit_unless_managed` and `rollback_unless_managed`, also defined in `django.db.transaction`,
  - the `TRANSACTIONS_MANAGED` setting.
- The `cycle` and `firstof` template tags will auto-escape their arguments. In 1.6 and 1.7, this behavior is provided by the version of these tags in the future template tag library.
- The `SEND_BROKEN_LINK_EMAILS` setting will be removed. Add the `django.middleware.common.BrokenLinkEmailsMiddleware` middleware to your `MIDDLEWARE_CLASSES` setting instead.
- `django.middleware.doc.XViewMiddleware` will be removed. Use `django.contrib.admindocs.middleware.XViewMiddleware` instead.
- `Model._meta.module_name` was renamed to `model_name`.
- Remove the backward compatible shims introduced to rename `get_query_set` and similar `queryset` methods. This affects the following classes: `BaseModelAdmin`, `ChangeList`, `BaseCommentNode`, `GenericForeignKey`, `Manager`, `SingleRelatedObjectDescriptor` and `ReverseSingleRelatedObjectDescriptor`.
- Remove the backward compatible shims introduced to rename the attributes `ChangeList.root_query_set` and `ChangeList.query_set`.
- `django.views.defaults.shortcut` will be removed, as part of the goal of removing all `django.contrib` references from the core Django codebase. Instead use `django.contrib.contenttypes.views.shortcut`. `django.conf.urls.shortcut` will also be removed.
- Support for the Python Imaging Library (PIL) module will be removed, as it no longer appears to be actively maintained & does not work on Python 3. You are advised to install [Pillow](#), which should be used instead.
- The following private APIs will be removed:
  - `django.db.backend`
  - `django.db.close_connection()`
  - `django.db.backends.creation.BaseDatabaseCreation.set_autocommit()`
  - `django.db.transaction.is_managed()`
  - `django.db.transaction.managed()`
- `django.forms.widgets.RadioButton` will be removed in favor of `django.forms.widgets.RadioChoiceInput`.
- The module `django.test.simple` and the class `django.test.simple.DjangoTestSuiteRunner` will be removed. Instead use `django.test.runner.DiscoverRunner`.
- The module `django.test._doctest` will be removed. Instead use the `doctest` module from the Python standard library.
- The `CACHE_MIDDLEWARE_ANONYMOUS_ONLY` setting will be removed.

- Usage of the hard-coded *Hold down “Control”, or “Command” on a Mac, to select more than one.* string to override or append to user-provided `help_text` in forms for ManyToMany model fields will not be performed by Django anymore either at the model or forms layer.
- The `Model._meta.get_(add|change|delete)_permission` methods will be removed.
- The session key `django_language` will no longer be read for backwards compatibility.
- Geographic Sitemaps will be removed (`django.contrib.gis.sitemaps.views.index` and `django.contrib.gis.sitemaps.views.sitemap`).
- `django.utils.html.fix_ampersands`, the `fix_ampersands` template filter and `django.utils.html.clean_html` will be removed following an accelerated deprecation.

## 10.8.5 1.7

See the *Django 1.5 release notes* for more details on these changes.

- The module `django.utils.simplejson` will be removed. The standard library provides `json` which should be used instead.
- The function `django.utils.itercompat.product` will be removed. The Python builtin version should be used instead.
- Auto-correction of `INSTALLED_APPS` and `TEMPLATE_DIRS` settings when they are specified as a plain string instead of a tuple will be removed and raise an exception.
- The `mimetype` argument to the `__init__` methods of `HttpResponse`, `SimpleTemplateResponse`, and `TemplateResponse`, will be removed. `content_type` should be used instead. This also applies to the `render_to_response()` shortcut and the sitemap views, `index()` and `sitemap()`.
- When `HttpResponse` is instantiated with an iterator, or when `content` is set to an iterator, that iterator will be immediately consumed.
- The `AUTH_PROFILE_MODULE` setting, and the `get_profile()` method on the `User` model, will be removed.
- The `cleanup` management command will be removed. It’s replaced by `clearsessions`.
- The `daily_cleanup.py` script will be removed.
- The `depth` keyword argument will be removed from `select_related()`.
- The undocumented `get_warnings_state()/restore_warnings_state()` functions from `django.test.utils` and the `save_warnings_state()/restore_warnings_state()` `django.test.TestCase` methods are deprecated. Use the `warnings.catch_warnings` context manager available starting with Python 2.6 instead.
- The undocumented `check_for_test_cookie` method in `AuthenticationForm` will be removed following an accelerated deprecation. Users subclassing this form should remove calls to this method, and instead ensure that their auth related views are CSRF protected, which ensures that cookies are enabled.
- The version of `django.contrib.auth.views.password_reset_confirm()` that supports base36 encoded user IDs (`django.contrib.auth.views.password_reset_confirm_uidb36`) will be removed. If your site has been running Django 1.6 for more than `PASSWORD_RESET_TIMEOUT_DAYS`, this change will have no effect. If not, then any password reset links generated before you upgrade to Django 1.7 won’t work after the upgrade.
- The `django.utils.encoding.StrAndUnicode` mix-in will be removed. Define a `__str__` method and apply the `python_2_unicode_compatible()` decorator instead.

## 10.8.6 1.6

See the *Django 1.4 release notes* for more details on these changes.

- `django.contrib.databrowse` will be removed.
- `django.contrib.localflavor` will be removed following an accelerated deprecation.
- `django.contrib.markup` will be removed following an accelerated deprecation.
- The compatibility modules `django.utils.copycompat` and `django.utils.hashcompat` as well as the functions `django.utils.itercompat.all` and `django.utils.itercompat.any` will be removed. The Python builtin versions should be used instead.
- The `csrf_response_exempt` and `csrf_view_exempt` decorators will be removed. Since 1.4 `csrf_response_exempt` has been a no-op (it returns the same function), and `csrf_view_exempt` has been a synonym for `django.views.decorators.csrf.csrf_exempt`, which should be used to replace it.
- The `django.core.cache.backends.memcached.CacheClass` backend was split into two in Django 1.3 in order to introduce support for PyLibMC. The historical `CacheClass` will be removed in favor of `django.core.cache.backends.memcached.MemcachedCache`.
- The UK-prefixed objects of `django.contrib.localflavor.uk` will only be accessible through their GB-prefixed names (GB is the correct ISO 3166 code for United Kingdom).
- The `IGNORABLE_404_STARTS` and `IGNORABLE_404_ENDS` settings have been superseded by `IGNORABLE_404_URLS` in the 1.4 release. They will be removed.
- The form wizard has been refactored to use class-based views with pluggable backends in 1.4. The previous implementation will be removed.
- Legacy ways of calling `cache_page()` will be removed.
- The backward-compatibility shim to automatically add a debug-false filter to the 'mail\_admins' logging handler will be removed. The `LOGGING` setting should include this filter explicitly if it is desired.
- The builtin truncation functions `django.utils.text.truncate_words()` and `django.utils.text.truncate_html_words()` will be removed in favor of the `django.utils.text.Truncator` class.
- The `django.contrib.gis.geoip.GeoIP` class was moved to `django.contrib.gis.geoip` in 1.4 – the shortcut in `django.contrib.gis.utils` will be removed.
- `django.conf.urls.defaults` will be removed. The functions `include()`, `patterns()` and `url()` plus `handler404`, `handler500`, are now available through `django.conf.urls`.
- The functions `setup_envron()` and `execute_manager()` will be removed from `django.core.management`. This also means that the old (pre-1.4) style of `manage.py` file will no longer work.
- Setting the `is_safe` and `needs_autoescape` flags as attributes of template filter functions will no longer be supported.
- The attribute `HttpRequest.raw_post_data` was renamed to `HttpRequest.body` in 1.4. The backward compatibility will be removed – `HttpRequest.raw_post_data` will no longer work.
- The value for the `post_url_continue` parameter in `ModelAdmin.response_add()` will have to be either `None` (to redirect to the newly created object's edit page) or a pre-formatted url. String formats, such as the previous default `'../%s/'`, will not be accepted any more.

## 10.8.7 1.5

See the *Django 1.3 release notes* for more details on these changes.

- Starting Django without a `SECRET_KEY` will result in an exception rather than a `DeprecationWarning`. (This is accelerated from the usual deprecation path; see the *Django 1.4 release notes*.)
- The `mod_python` request handler will be removed. The `mod_wsgi` handler should be used instead.
- The `template` attribute on `django.test.client.Response` objects returned by the *test client* will be removed. The `templates` attribute should be used instead.
- The `django.test.simple.DjangoTestRunner` will be removed. Instead use a unittest-native class. The features of the `django.test.simple.DjangoTestRunner` (including fail-fast and Ctrl-C test termination) can currently be provided by the unittest-native `TextTestRunner`.
- The undocumented function `django.contrib.formtools.utils.security_hash` will be removed, instead use `django.contrib.formtools.utils.form_hmac`
- The function-based generic view modules will be removed in favor of their class-based equivalents, outlined *here*.
- The `django.core.servers.basehttp.AdminMediaHandler` will be removed. In its place use `django.contrib.staticfiles.handlers.StaticFilesHandler`.
- The template tags library `adminmedia` and the template tag `{% admin_media_prefix %}` will be removed in favor of the generic static files handling. (This is faster than the usual deprecation path; see the *Django 1.4 release notes*.)
- The `url` and `ssi` template tags will be modified so that the first argument to each tag is a template variable, not an implied string. In 1.4, this behavior is provided by a version of the tag in the *future* template tag library.
- The `reset` and `sqlreset` management commands will be removed.
- Authentication backends will need to support an inactive user being passed to all methods dealing with permissions. The `supports_inactive_user` attribute will no longer be checked and can be removed from custom backends.
- `transform()` will raise a `GEOSEException` when called on a geometry with no SRID value.
- `django.http.CompatCookie` will be removed in favor of `django.http.SimpleCookie`.
- `django.core.context_processors.PermWrapper` and `django.core.context_processors.PermLookupDict` will be removed in favor of the corresponding `django.contrib.auth.context_processors.PermWrapper` and `django.contrib.auth.context_processors.PermLookupDict`, respectively.
- The `MEDIA_URL` or `STATIC_URL` settings will be required to end with a trailing slash to ensure there is a consistent way to combine paths in templates.
- `django.db.models.fields.URLField.verify_exists` will be removed. The feature was deprecated in 1.3.1 due to intractable security and performance issues and will follow a slightly accelerated deprecation timeframe.
- Translations located under the so-called *project path* will be ignored during the translation building process performed at runtime. The `LOCALE_PATHS` setting can be used for the same task by including the filesystem path to a `locale` directory containing non-app-specific translations in its value.
- The Markup contrib app will no longer support versions of Python-Markdown library earlier than 2.1. An accelerated timeline was used as this was a security related deprecation.
- The `CACHE_BACKEND` setting will be removed. The cache backend(s) should be specified in the `CACHES` setting.

## 10.8.8 1.4

See the *Django 1.2 release notes* for more details on these changes.

- `CsrfResponseMiddleware` and `CsrfMiddleware` will be removed. Use the `{% csrf_token %}` template tag inside forms to enable CSRF protection. `CsrfViewMiddleware` remains and is enabled by default.
- The old imports for CSRF functionality (`django.contrib.csrf.*`), which moved to core in 1.2, will be removed.
- The `django.contrib.gis.db.backend` module will be removed in favor of the specific backends.
- `SMTPConnection` will be removed in favor of a generic Email backend API.
- The many to many SQL generation functions on the database backends will be removed.
- The ability to use the `DATABASE_*` family of top-level settings to define database connections will be removed.
- The ability to use shorthand notation to specify a database backend (i.e., `sqlite3` instead of `django.db.backends.sqlite3`) will be removed.
- The `get_db_prep_save`, `get_db_prep_value` and `get_db_prep_lookup` methods will have to support multiple databases.
- The Message model (in `django.contrib.auth`), its related manager in the User model (`user.message_set`), and the associated methods (`user.message_set.create()` and `user.get_and_delete_messages()`), will be removed. The *messages framework* should be used instead. The related `messages` variable returned by the auth context processor will also be removed. Note that this means that the admin application will depend on the messages context processor.
- Authentication backends will need to support the `obj` parameter for permission checking. The `supports_object_permissions` attribute will no longer be checked and can be removed from custom backends.
- Authentication backends will need to support the `AnonymousUser` class being passed to all methods dealing with permissions. The `supports_anonymous_user` variable will no longer be checked and can be removed from custom backends.
- The ability to specify a callable template loader rather than a `Loader` class will be removed, as will the `load_template_source` functions that are included with the built in template loaders for backwards compatibility.
- `django.utils.translation.get_date_formats()` and `django.utils.translation.get_partial_date_formats()`. These functions will be removed; use the locale-aware `django.utils.formats.get_format()` to get the appropriate formats.
- In `django.forms.fields`, the constants: `DEFAULT_DATE_INPUT_FORMATS`, `DEFAULT_TIME_INPUT_FORMATS` and `DEFAULT_DATETIME_INPUT_FORMATS` will be removed. Use `django.utils.formats.get_format()` to get the appropriate formats.
- The ability to use a function-based test runner will be removed, along with the `django.test.simple.run_tests()` test runner.
- The `views.feed()` view and `feeds.Feed` class in `django.contrib.syndication` will be removed. The class-based view `views.Feed` should be used instead.
- `django.core.context_processors.auth`. This release will remove the old method in favor of the new method in `django.contrib.auth.context_processors.auth`.
- The `postgresql` database backend will be removed, use the `postgresql_psycopg2` backend instead.
- The `no` language code will be removed and has been replaced by the `nb` language code.

- Authentication backends will need to define the boolean attribute `supports_inactive_user` until version 1.5 when it will be assumed that all backends will handle inactive users.
- `django.db.models.fields.XMLField` will be removed. This was deprecated as part of the 1.3 release. An accelerated deprecation schedule has been used because the field hasn't performed any role beyond that of a simple `TextField` since the removal of `oldforms`. All uses of `XMLField` can be replaced with `TextField`.
- The undocumented `mixin` parameter to the `open()` method of `django.core.files.storage.Storage` (and subclasses) will be removed.

### 10.8.9 1.3

See the *Django 1.1 release notes* for more details on these changes.

- `AdminSite.root()`. This method of hooking up the admin URLs will be removed in favor of including `admin.site.urls`.
- Authentication backends need to define the boolean attributes `supports_object_permissions` and `supports_anonymous_user` until version 1.4, at which point it will be assumed that all backends will support these options.

## 10.9 The Django source code repository

When deploying a Django application into a real production environment, you will almost always want to use an [official packaged release of Django](#).

However, if you'd like to try out in-development code from an upcoming release or contribute to the development of Django, you'll need to obtain a clone of Django's source code repository.

This document covers the way the code repository is laid out and how to work with and find things in it.

### 10.9.1 High-level overview

The Django source code repository uses [Git](#) to track changes to the code over time, so you'll need a copy of the Git client (a program called `git`) on your computer, and you'll want to familiarize yourself with the basics of how Git works.

Git's website offers downloads for various operating systems. The site also contains vast amounts of [documentation](#).

The Django Git repository is located online at [github.com/django/django](https://github.com/django/django). It contains the full source code for all Django releases, which you can browse online.

The Git repository includes several [branches](#):

- `master` contains the main in-development code which will become the next packaged release of Django. This is where most development activity is focused.
- `stable/A.B.x` are the branches where release preparation work happens. They are also used for bugfix and security releases which occur as necessary after the initial release of a feature version.
- `soc20XX/<project>` branches were used by students who worked on Django during the 2009 and 2010 Google Summer of Code programs.
- `attic/<project>` branches were used to develop major or experimental new features without affecting the rest of Django's code.

The Git repository also contains `tags`. These are the exact revisions from which packaged Django releases were produced, since version 1.0.

The source code for the [Djangoproject.com](http://Djangoproject.com) website can be found at [github.com/django/djangoproject.com](https://github.com/django/djangoproject.com).

## 10.9.2 The master branch

If you'd like to try out the in-development code for the next release of Django, or if you'd like to contribute to Django by fixing bugs or developing new features, you'll want to get the code from the master branch.

Note that this will get *all* of Django: in addition to the top-level `django` module containing Python code, you'll also get a copy of Django's documentation, test suite, packaging scripts and other miscellaneous bits. Django's code will be present in your clone as a directory named `django`.

To try out the in-development code with your own applications, simply place the directory containing your clone on your Python import path. Then `import` statements which look for Django will find the `django` module within your clone.

If you're going to be working on Django's code (say, to fix a bug or develop a new feature), you can probably stop reading here and move over to [the documentation for contributing to Django](#), which covers things like the preferred coding style and how to generate and submit a patch.

## 10.9.3 Other branches

Django uses branches to prepare for releases of Django.

In the past when Django was hosted on Subversion, branches were also used for feature development. Now Django is hosted on Git and feature development is done on contributor's forks, but the Subversion feature branches remain in Git for historical reference.

### Stable branches

These branches can be found in the repository as `stable/A.B.x` branches and will be created right after the first alpha is tagged.

For example, immediately after *Django 1.5 alpha 1* was tagged, the branch `stable/1.5.x` was created and all further work on preparing the code for the final 1.5 release was done there.

These branches also provide limited bugfix support for the most recent released version of Django and security support for the two most recently-released versions of Django.

For example, after the release of Django 1.5, the branch `stable/1.5.x` receives only fixes for security and critical stability bugs, which are eventually released as Django 1.5.1 and so on, `stable/1.4.x` receives only security fixes, and `stable/1.3.x` no longer receives any updates.

---

### Historical information

This policy for handling `stable/A.B.x` branches was adopted starting with the Django 1.5 release cycle.

Previously, these branches weren't created until right after the releases and the stabilization work occurred on the main repository branch. Thus, no new features development work for the next release of Django could be committed until the final release happened.

For example, shortly after the release of Django 1.3 the branch `stable/1.3.x` was created. Official support for that release has expired, and so it no longer receives direct maintenance from the Django project. However, that and

all other similarly named branches continue to exist and interested community members have occasionally used them to provide unofficial support for old Django releases.

---

## Feature-development branches

---

### Historical information

Since Django moved to Git in 2012, anyone can clone the repository and create their own branches, alleviating the need for official branches in the source code repository.

The following section is mostly useful if you're exploring the repository's history, for example if you're trying to understand how some features were designed.

---

Feature-development branches tend by their nature to be temporary. Some produce successful features which are merged back into Django's master to become part of an official release, but others do not; in either case there comes a time when the branch is no longer being actively worked on by any developer. At this point the branch is considered closed.

Unfortunately, Django used to be maintained with the Subversion revision control system, that has no standard way of indicating this. As a workaround, branches of Django which are closed and no longer maintained were moved into `attic`.

For reference, the following are branches whose code eventually became part of Django itself, and so are no longer separately maintained:

- `boulder-oracle-sprint`: Added support for Oracle databases to Django's object-relational mapper. This has been part of Django since the 1.0 release.
- `gis`: Added support for geographic/spatial queries to Django's object-relational mapper. This has been part of Django since the 1.0 release, as the bundled application `django.contrib.gis`.
- `il18n`: Added *internationalization support* to Django. This has been part of Django since the 0.90 release.
- `magic-removal`: A major refactoring of both the internals and public APIs of Django's object-relational mapper. This has been part of Django since the 0.95 release.
- `multi-auth`: A refactoring of *Django's bundled authentication framework* which added support for *authentication backends*. This has been part of Django since the 0.95 release.
- `new-admin`: A refactoring of *Django's bundled administrative application*. This became part of Django as of the 0.91 release, but was superseded by another refactoring (see next listing) prior to the Django 1.0 release.
- `newforms-admin`: The second refactoring of Django's bundled administrative application. This became part of Django as of the 1.0 release, and is the basis of the current incarnation of `django.contrib.admin`.
- `queryset-refactor`: A refactoring of the internals of Django's object-relational mapper. This became part of Django as of the 1.0 release.
- `unicode`: A refactoring of Django's internals to consistently use Unicode-based strings in most places within Django and Django applications. This became part of Django as of the 1.0 release.

When Django moved from SVN to Git, the information about branch merges wasn't preserved in the source code repository. This means that the `master` branch of Django doesn't contain merge commits for the above branches.

However, this information is [available as a grafts file](#). You can restore it by putting the following lines in `.git/info/grafts` in your local clone:

```
ac64e91a0cad57f4bc5cd5d66955832320ca7a1 553a20075e6991e7a60baee51ea68c8adc520d9a_

```

Additionally, the following branches are closed, but their code was never merged into Django and the features they aimed to implement were never finished:

- full-history
- generic-auth
- multiple-db-support
- per-object-permissions
- schema-evolution
- schema-evolution-ng
- search-api
- sqlalchemy

All of the above-mentioned branches now reside in `attic`.

Finally, the repository contains `soc2009/xxx` and `soc2010/xxx` feature branches, used for Google Summer of Code projects.

## 10.9.4 Tags

Each Django release is tagged and signed by a *releaser*.

The tags can be found on GitHub's [tags](#) page.

## 10.10 How is Django Formed?

This document explains how to release Django.

**Please, keep these instructions up-to-date if you make changes!** The point here is to be descriptive, not prescriptive, so feel free to streamline or otherwise make changes, but **update this document accordingly!**

## 10.10.1 Overview

There are three types of releases that you might need to make:

- Security releases: disclosing and fixing a vulnerability. This'll generally involve two or three simultaneous releases – e.g. 1.5.x, 1.6.x, and, depending on timing, perhaps a 1.7 alpha/beta/rc.
- Regular version releases: either a final release (e.g. 1.5) or a bugfix update (e.g. 1.5.1).
- Pre-releases: e.g. 1.6 alpha, beta, or rc.

The short version of the steps involved is:

1. If this is a security release, pre-notify the security distribution list one week before the actual release.
2. Proofread the release notes, looking for organization and writing errors. Draft a blog post and email announcement.
3. Update version numbers and create the release package(s).
4. Upload the package(s) to the `djangoproject.com` server.
5. Upload the new version(s) to PyPI.
6. Declare the new version in the admin on `djangoproject.com`.
7. Post the blog entry and send out the email announcements.
8. Update version numbers post-release.

There are a lot of details, so please read on.

## 10.10.2 Prerequisites

You'll need a few things before getting started:

- A GPG key. If the key you want to use is not your default signing key, you'll need to add `-u you@example.com` to every GPG signing command below, where `you@example.com` is the email address associated with the key you want to use.
- An install of some required Python packages:

```
$ pip install wheel twine
```

- Access to Django's record on PyPI. Create a file with your credentials:

```
/.pypirc
[pypi]
username:YourUsername
password:YourPassword
```

- Access to the `djangoproject.com` server to upload files.
- Access to the admin on `djangoproject.com` as a "Site maintainer".
- Access to post to `django-announce`.
- If this is a security release, access to the pre-notification distribution list.

If this is your first release, you'll need to coordinate with James and/or Jacob to get all these things lined up.

### 10.10.3 Pre-release tasks

A few items need to be taken care of before even beginning the release process. This stuff starts about a week before the release; most of it can be done any time leading up to the actual release:

1. If this is a security release, send out pre-notification **one week** before the release. We maintain a list of who gets these pre-notification emails in the private `django-core` repository. Send the mail to `security@djangoproject.com` and BCC the pre-notification recipients. This email should be signed by the key you'll use for the release, and should include patches for each issue being fixed.
2. As the release approaches, watch Trac to make sure no release blockers are left for the upcoming release.
3. Check with the other committers to make sure they don't have any uncommitted changes for the release.
4. Proofread the release notes, including looking at the online version to catch any broken links or reST errors, and make sure the release notes contain the correct date.
5. Double-check that the release notes mention deprecation timelines for any APIs noted as deprecated, and that they mention any changes in Python version support.
6. Double-check that the release notes index has a link to the notes for the new release; this will be in `docs/releases/index.txt`.
7. If this is a feature release, ensure translations from Transifex have been integrated. This is typically done by a separate translation's manager rather than the releaser, but here are the steps. Provided you have an account on Transifex:

```
$ python scripts/manage_translations.py fetch
```

and then commit the changed/added files (both `.po` and `.mo`). Sometimes there are validation errors which need to be debugged, so avoid doing this task immediately before a release is needed.

8. *Update the django-admin manual page:*

```
$ cd docs
$ make man
$ man _build/man/django-admin.1 # do a quick sanity check
$ cp _build/man/django-admin.1 man/django-admin.1
```

and then commit the changed man page.

### 10.10.4 Preparing for release

Write the announcement blog post for the release. You can enter it into the admin at any time and mark it as inactive. Here are a few examples: [example security release announcement](#), [example regular release announcement](#), [example pre-release announcement](#).

### 10.10.5 Actually rolling the release

OK, this is the fun part, where we actually push out a release!

1. Check [Jenkins](#) is green for the version(s) you're putting out. You probably shouldn't issue a release until it's green.
2. A release always begins from a release branch, so you should make sure you're on a stable branch and up-to-date. For example:

```
$ git checkout stable/1.5.x
$ git pull
```

3. If this is a security release, merge the appropriate patches from `django-private`. Rebase these patches as necessary to make each one a simple commit on the release branch rather than a merge commit. To ensure this, merge them with the `--ff-only` flag; for example:

```
$ git checkout stable/1.5.x
$ git merge --ff-only security/1.5.x
```

(This assumes `security/1.5.x` is a branch in the `django-private` repo containing the necessary security patches for the next release in the 1.5 series.)

If `git` refuses to merge with `--ff-only`, switch to the `security-patch` branch and rebase it on the branch you are about to merge it into (`git checkout security/1.5.x; git rebase stable/1.5.x`) and then switch back and do the merge. Make sure the commit message for each security fix explains that the commit is a security fix and that an announcement will follow ([example security commit](#)).

4. For a feature release, remove the `UNDER DEVELOPMENT` header at the top of the release notes and add the release date on the next line. For a patch release, replace `*Under Development*` with the release date. Make this change on all branches where the release notes for a particular version are located.
5. Update the version number in `django/__init__.py` for the release. Please see [notes on setting the VERSION tuple](#) below for details on `VERSION`.
6. If this is a pre-release package, update the “Development Status” trove classifier in `setup.py` to reflect this. Otherwise, make sure the classifier is set to `Development Status :: 5 - Production/Stable`.
7. Tag the release using `git tag`. For example:

```
$ git tag --sign --message="Tag 1.5.1" 1.5.1
```

You can check your work by running `git tag --verify <tag>`.

8. Push your work, including the tag: `git push --tags`.
9. Make sure you have an absolutely clean tree by running `git clean -dfx`.
10. Run `make -f extras/Makefile` to generate the release packages. This will create the release packages in a `dist/` directory.
11. Generate the hashes of the release packages:

```
$ cd dist
$ md5sum *
$ sha1sum *
$ sha256sum *
```

12. Create a “checksums” file, `Django-<<VERSION>>.checksum.txt` containing the hashes and release information. Start with this template and insert the correct version, date, GPG key ID (from `gpg --list-keys --keyid-format LONG`), release URL, and checksums:

```
This file contains MD5, SHA1, and SHA256 checksums for the source-code
tarball and wheel files of Django <<VERSION>>, released <<DATE>>.
```

```
To use this file, you will need a working install of PGP or other
compatible public-key encryption software. You will also need to have
the Django release manager's public key in your keyring; this key has
the ID ``XXXXXXXXXXXXXXXXXX`` and can be imported from the MIT
keyserver. For example, if using the open-source GNU Privacy Guard
```

```
implementation of PGP:

    gpg --keyserver pgp.mit.edu --recv-key XXXXXXXXXXXXXXXXXXXX

Once the key is imported, verify this file::

    gpg --verify <<THIS FILENAME>>

Once you have verified this file, you can use normal MD5, SHA1, or SHA256
checksumming applications to generate the checksums of the Django
package and compare them to the checksums listed below.

Release packages:
=====

https://www.djangoproject.com/m/releases/<<RELEASE TAR.GZ FILENAME>>
https://www.djangoproject.com/m/releases/<<RELEASE WHL FILENAME>>

MD5 checksums:
=====

<<MD5SUM>> <<RELEASE TAR.GZ FILENAME>>
<<MD5SUM>> <<RELEASE WHL FILENAME>>

SHA1 checksums:
=====

<<SHA1SUM>> <<RELEASE TAR.GZ FILENAME>>
<<SHA1SUM>> <<RELEASE WHL FILENAME>>

SHA256 checksums:
=====

<<SHA256SUM>> <<RELEASE TAR.GZ FILENAME>>
<<SHA256SUM>> <<RELEASE WHL FILENAME>>
```

13. Sign the checksum file (`gpg --clearsign --digest-algo SHA256 Django-<version>.checksum.txt`). This generates a signed document, `Django-<version>.checksum.txt.asc` which you can then verify using `gpg --verify Django-<version>.checksum.txt.asc`.

If you're issuing multiple releases, repeat these steps for each release.

### 10.10.6 Making the release(s) available to the public

Now you're ready to actually put the release out there. To do this:

1. Upload the release package(s) to the django project server, replacing A.B. with the appropriate version number, e.g. 1.5 for a 1.5.x release:

```
$ scp Django-* django project.com:/home/www/www/media/releases/A.B
```

2. Upload the checksum file(s):

```
$ scp Django-A.B.C.checksum.txt.asc django project.com:/home/www/www/media/pgp/
↪ Django-A.B.C.checksum.txt
```

- Test that the release packages install correctly using `easy_install` and `pip`. Here’s one method (which requires `virtualenvwrapper`):

```
$ RELEASE_VERSION='1.7.2'
$ MAJOR_VERSION=`echo $RELEASE_VERSION| cut -c 1-3`

$ mktmpenv
$ easy_install https://www.djangoproject.com/m/releases/$MAJOR_VERSION/Django-
→$RELEASE_VERSION.tar.gz
$ deactivate
$ mktmpenv
$ pip install https://www.djangoproject.com/m/releases/$MAJOR_VERSION/Django-
→$RELEASE_VERSION.tar.gz
$ deactivate
$ mktmpenv
$ pip install https://www.djangoproject.com/m/releases/$MAJOR_VERSION/Django-
→$RELEASE_VERSION-py2.py3-none-any.whl
$ deactivate
```

This just tests that the tarballs are available (i.e. redirects are up) and that they install correctly, but it’ll catch silly mistakes.

- Ask a few people on IRC to verify the checksums by visiting the checksums file (e.g. <https://www.djangoproject.com/m/pgp/Django-1.5b1.checksum.txt>) and following the instructions in it. For bonus points, they can also unpack the downloaded release tarball and verify that its contents appear to be correct (proper version numbers, no stray `.pyc` or other undesirable files).
- Upload the release packages to PyPI (for pre-releases, only upload the wheel file):

```
$ twine upload -s dist/*
```

- Go to the [Add release page in the admin](#), enter the new release number exactly as it appears in the name of the tarball (Django-<version>.tar.gz). So for example enter “1.5.1” or “1.4c2”, etc. If the release is part of an LTS branch, mark it so.
- Make the blog post announcing the release live.
- For a new version release (e.g. 1.5, 1.6), update the default stable version of the docs by flipping the `is_default` flag to `True` on the appropriate `DocumentRelease` object in the `docs.djangoproject.com` database (this will automatically flip it to `False` for all others); you can do this using the site’s admin.
- Post the release announcement to the [django-announce](#), [django-developers](#), and [django-users](#) mailing lists. This should include a link to the announcement blog post. If this is a security release, also include [oss-security@lists.openwall.com](mailto:oss-security@lists.openwall.com).
- Add a link to the blog post in the topic of the `#django` IRC channel: `/msg chanserv TOPIC #django new topic goes here.`

## 10.10.7 Post-release

You’re almost done! All that’s left to do now is:

- Update the `VERSION` tuple in `django/__init__.py` again, incrementing to whatever the next expected release will be. For example, after releasing 1.5.1, update `VERSION` to `VERSION = (1, 5, 2, 'alpha', 0)`.
- Add the release in [Trac’s versions list](#) if necessary (and make it the default if it’s a final release). Not all versions are declared; take example on previous releases.

3. If this was a security release, update *Archive of security issues* with details of the issues addressed.

## 10.10.8 New stable branch tasks

There are several items to do in the time following the creation of a new stable branch (often following an alpha release). Some of these tasks don't need to be done by the releaser.

1. Create a new `DocumentRelease` object in the `docs.djangoproject.com` database for the new version's docs, and update the `docs/fixtures/doc_releases.json` JSON fixture, so people without access to the production DB can still run an up-to-date copy of the docs site.
2. Create a stub release note for the new feature version. Use the stub from the previous feature release version or copy the contents from the previous feature version and delete most of the contents leaving only the headings.
3. Increase the default PBKDF2 iterations in `django.contrib.auth.hashers.PBKDF2PasswordHasher` by about 20% (pick a round number). Run the tests, and update the 3 failing hasher tests with the new values. Make sure this gets noted in the release notes (see the 1.8 release notes for an example).
4. Remove features that have reached the end of their deprecation cycle. Each removal should be done in a separate commit for clarity. In the commit message, add a "refs #XXXX" to the original ticket where the deprecation began if possible.
5. Remove `.. versionadded::`, `.. versionadded::`, and `.. deprecated::` annotations in the documentation from two releases ago. For example, in Django 1.9, notes for 1.7 will be removed.
6. Add the new branch to [Read the Docs](#). Since the automatically generated version names ("stable-A.B.x") differ from the version numbers we've used historically in Read the Docs ("A.B.x"), we currently ask Eric Holscher to add the version for us. Someday the alias functionality may be built-in to the Read the Docs UI.

## 10.10.9 Notes on setting the VERSION tuple

Django's version reporting is controlled by the `VERSION` tuple in `django/__init__.py`. This is a five-element tuple, whose elements are:

1. Major version.
2. Minor version.
3. Micro version.
4. Status – can be one of "alpha", "beta", "rc" or "final".
5. Series number, for alpha/beta/RC packages which run in sequence (allowing, for example, "beta 1", "beta 2", etc.).

For a final release, the status is always "final" and the series number is always 0. A series number of 0 with an "alpha" status will be reported as "pre-alpha".

Some examples:

- `(1, 2, 1, 'final', 0)` → "1.2.1"
- `(1, 3, 0, 'alpha', 0)` → "1.3 pre-alpha"
- `(1, 3, 0, 'beta', 2)` → "1.3 beta 2"
